Among the more important articles in this Volume are the following:

**PRESIDENT PROPHETS.** JESUS COLLIANS, M.P.
**PEKING** ............... Professor Legge.
**PELASGIANS; FLUTA** ..... F. B. Jevons.
**PELVIS** ................ Dr. David Hebrurn.
**PENDULUM** .............. E. A. Keane.
**PENNANT; HAPIE** ...... Frank D. Greene, M.A.
**PHILOSOPHY (Arts)** ... Lewis Col. Dunlop, R.A.

**NAVY** .................. Cape. Garnett, R.N.
**PENATECH; PETER** ...... Rev. J. Sutherland Black.
**PETS** .................. H. B. Wreathe.
**PERFUMERY** ............ C. A. Pierre.
**PERIODICALS** .......... W. T. Stead.
**PERSIA; PERSSEPOLIS** ... Major-Gen. Sir R. Murdoch Smith.
**PERU; PIZARRO** ........ Sir Clements R. Markham, K.C.B.
**PERSIMMON** ............ Professor W. Caldwell.
**PETERBOROUGH** ........ II. D. Thayl.
**PETRARCH** .............. Sigismund Cantagalli.
**PETROGRAPHY, &c** ...... Professor James Geikie.
**PETROLEUM** ............. Henry C. Foller, Junr.
**PHILADELPHIA** .......... W. S. Washington.
**PHILIPPINE ISLANDS** ... Professor A. H. Krane.
**PHILOLOGY** ............. John Pelle, LL.D.
**PHILOSOPHY, &c** ...... Professor Phineas Pattison.
**PHOENICIA** ............ Charles Rawlinson.
**PHONETICS** ............. Dr. A. J. Ellis.
**PHONOGRAPH** ............ Thomas A. Edison.
**PHILOSOPHERS** .......... E. W. Hyble.
**PHOTOGRAPHY** .......... T. C. Hepworth & T. W. Baseford.
**PHILOSOPHY; PLANTS** ... Norman Wylde.
**PIANO** .................. J. F. Rowbotham.
**PICTURES** .............. A. M. Bay.
**PICTURE** ............... F. T. Cunningham.
**PINDAR; PLAUTUS** ...... John Mason.
**PINE** .................. W. Sutherland.
**PIQUET; POKER** ......... Henry Jones (‘Cavendish’).
**PISCICULTURE** .......... Sir James G. Maitland, Bart.
**PICT** .................. W. E. H. Locky, M.P.
**PITTSBURGH** ............ B. C. Jillson, M.D.
**PLANETS; PTOLEMY** .... Rev. E. B. Kirk.
**PLATO** .................. D. G. Ritchie.
**PLEURO-PNEUMONIA** ... Principal Williams.
**PLIQUE; POTATO** ....... James MacDonal.
**PLUTARCH** .............. Rev. H. A. Holdens, LL.D.
**PLYMOUTH** ............. F. N. Worth.
**PNEUMONIA** ............. Dr. Lunde.
**POACHING** .............. C. N. Johnstone.
**POE, EDGAR ALLAN** .... Rev. Professor F. M. Bird.
**POETRY** ................ Edmund Gosse, LL.D.
**POISON** ............... Professor Ralph Stockman.
**POLEN** .................. R. W. Morrill.
**POLAR EXPLORATION** ... John S. Kellett, LL.D.
**POLAR, CARDINAL** ...... T. G. Law, J.L.D.
**POLICE** ................. James Monro, C.B.
**POLITICAL ECONOMY** ... T. Kirkup.
**POLYNESSIA** ............. Professor A. H. Krane.
**POMPES; PLINT** ......... Dr. J. F. Steele.
**POOR-LAWS** ............. W. C. Smith.
**POPES** .................. Rev. W. Hunt & F. A. Garquet, O.S.B.
**POPE, ALEXANDER** ...... Dr. H. D. Traill.
**POSITIVISM** ............ James Oliphant.
**POULTRY; RINO** ......... James Paton.
**PICKER** ................ Edward Browne.
**PRAETER-BOOK** .......... Bishop Dowden.
**PRESIDING; PHILO** ...... Thomas Davidson.

**PITIANCE** .............. J. Balfour Paul.
**PRE-RAPHAELITISM** ...... W. Holman Hunt.
**PRINTING** .............. John Southward.
**PRIOR; FRAZIO** ......... Austin Dobson.
**PRIESTS; E. D. CONN** ... Sir E. D. Cone, K.C.B.
**PRIORY-COUNCIL** ...... A. Wood Renton.
**PROBABILITIES** .......... E. E. Anderson.
**PROFIT-SHARING** ....... Robert Cochrane.
**PROTECTION** ............ W. Draper Lewis.
**PROTOPLASM** ............ J. A. Thomson.
**PROVENCAL** ............. A. P. Goudy.
**PROVERBS; QUEVEDO** .... John Gossby.
**PRUSSIA** ................ Findlay Murhead.
**PSALMS** ................ Professor T. K. Cheyne.
**PSYCHOLOGY** ............ Professor Sorley.
**PUERPERAL FEVER** ....... Dr. Milne Murray.
**PUFFLIES** ............... Henry Tinsen.
**PUNNY** .................. Rev. J. G. Johnston.
**PYRAMIA** ............... Professor Alex. Napier.
**PYRAMIDS** .............. Stanley Lane-Poole.
**QUIRATIONS** ............ Professor Knott.
**QUEBEC** ................ Dr. Stewart & J. G. Coleman, M.G.
**QUEENSLAND** ............ W. Senior.
**QUITO** .................. W. Dundas Walker.
**RAEULIS; REYNOLDS** ... Sir Walter Besant.
**RAEURN; RENNOLDS** .... J. M. Gray.
**RAILWAYS** ............... E. McDermott, of Railway News.
**RAINE** .................. Dr. Duchan.
**RAINBOW** ................ W. T. Godson.
**RALEIGH; RAGINE** ...... Thomas Davidson.
**RAHIL** .................. Sir Joseph Crowe, C.B.
**READ, CHARLES** ......... P. Hinde Groome.
**RECEIPTS; RECORDS** .... Walter Rye.
**RED SEA** ................ Sir John Murray.
**REFLECTION** ............ Dr. Alfred Daniell.
**REFORMATION; RENAN** ... P. Hume Brown.
**REFORMATORS** .......... Sir E. F. Cooke, K.G.B.
**REFRACTION** ............ Dr. Alfred Daniell.
**REGISTRATION** .......... Francis Watt.
**RELIGION** .............. Professor Flint.
**REMBRANDT** ............. P. G. Hamerton.
**REPRESENTATION** ...... Thomas Raleigh.
**REVOLUTION** ............ Thomas Jefferson.
**REVITALIZATION** ......... Norman Wylde.
**RESTITUTION** ........... Thackeray Turner.
**REVOLUTION** ............ Rev. J. Sutherland Black.
**REVOLVER** .............. W. W. Green.
**REVY** .................. J. T. Bealby.
**RICHARDSON, SAMUEL** ... Austin Dobson.
**RICHTER; REUTER** ...... J. T. Bealby.
**RIDING AND DRIVING** ... Captain Hayes.
**RIPLEYS** ............... Major-General Arbuthnot.
**RIGHT-HANDLESSNESS** ... James Shaw.
**RIGHT OF WAY** .......... G. E. W. Mactherson.
**RIVER** .................. Dr. Hutton Mill.
**RODNEY** ................ Professor J. K. Laughton.
**ROGERS** ................ F. Hinde Groome.
**ROMAN CATHOLICISM** ...... Rev. W. L. Gildea, B.D.
**ROMANCES; ROLAND** ...... John Omsby.
**ROBERTSON, Sir E. F.** ... Professor C. G. Robertson.
**ROME (Topography)** ...... Cardinal Isaac Taylor.

The Publishers beg to tender their thanks, for revising the articles ‘Penance’ and ‘Roman Catholic Church,’ to His Eminence Cardinal Manning; for ‘Pittsburgh,’ to Mr Andrew Carnegie; for ‘F. W. Robertson,’ to Rev. Stopford A. Brooke; for ‘Rosmini,’ to Father Lockhart; for ‘Profit-sharing,’ to Mr Alfred Dolok; for ‘Positivism,’ to Mr Frederic Harrison; for ‘Rochester,’ to Prebendary Levett; for ‘Peterhead,’ to Sir John Coode; and to the town-clerks of Peterborough, Preston, Rochdale, Rotherham, &c.
Peasant Proprietorship is a system of cultivation of small holdings of land by occupiers who own the land, or hold it on some secure or permanent tenure. Perhaps there is no question on which there is a greater diversity of opinion. On the one hand the small cultivator is held up as a pattern of industry, thrift, and prosperity, and on the other as an example of unceasing toil and miserable failure.

Arthur Young held that the best system of agriculture was that which secured the largest amount of produce from the land. It is evident, however, that another consideration of great importance must be taken into account—viz. the numbers, quality, and condition of those engaged in tilling the soil. Though nations might attain to brilliant positions by trade, commerce, and the accumulation of wealth, yet the permanent strength, the solvency, and resisting power of a country must closely depend on the number and condition of its rural population. Hence if it could be proved that vast areas of land could be cultivated at the greatest money profit, by means of machinery and a handful of labourers, yet such a method of cultivation would be adverse to the real interests of the nation as a whole.

There is substantial evidence, however, that small holdings of land are more productive in proportion than large farms, and that they are specially adapted to the production of certain kinds of food. It is from these causes that the rent value and purchase price of the smaller holdings in continental countries are so much higher than are found to obtain with the larger farms of Great Britain. It is frequently quoted in opposition to this view that the yield of corn per acre is much greater in England than on the Continent. This comparison, however, is of little value from the fact that the average of continental production is much lowered through the low yields of poor land, hillsides, and wastes, which, if in England, would not be cultivated at all. The evidence of the Royal Commission on Agriculture (1880) shows that the vast majority of holdings in the Netherlands are from 10 to 30 acres, held for the most part by cultivating owners, and that the small and medium-sized farms are generally the best cultivated and managed.

Mr Jenkins, the assistant commissioner, gave many examples of what he terms 'intensive' cultivation in Holland. One of these is that of a man who owned 22 acres of land, and rented 10 acres more. He had thirty milking cows in the fields, and ten feeding beasts in the stall. He fed every year thirty beasts besides his own cast cows, and spent above £600 per annum for food, principally for winter keep.

Belgium is rather a country of small cultivators than of peasant proprietors. If we leave out of account the owners of very small plots of land, it is the small tenant-farmer who is the most important element in Belgian agriculture. In spite, however, of excessive rents, the insecurity and other drawbacks of tenancies as compared with ownership, Belgium is a striking example of the advantages of la petite culture. M. de Laveleye states that Belgium is the best cultivated and the most productive country in the world; and refers to Flanders, with land naturally the worst in Europe, as a marvellous triumph of care, industry, and forethought on the part of the cultivators. According to the report above quoted, the available supply of milk and its products per head of the population is in Belgium about twice as great as that in Great Britain. In most districts in Belgium the labourer is a petit cultivateur—i.e. while hiring himself out as a labourer, he cultivates and often owns a piece of land stocked with rabbits, pigs, poultry, goats, and sometimes one or a couple of cows. A man of this class in the Ardennes, who was working with his son for a farmer at five francs per day, was found on inquiry by the present writer to be the owner of a cottage with 6 acres of land, two cows, and other smaller
but little hired labour, every member of the family doing something useful on the little holding. The system develops a hardiness, a fertility of resources, an adaptation of means to ends, and an incessant industry that makes of the peasant proprietor a model of competition with hired labour. As owner of his little holding the peasant proprietor has no restrictions as to cropping or methods of cultivation. He has no doubts about compensation for unexhausted manures and improvements, and no uncertainty as to tenure. He can cultivate his land as long as he lives and pass it on to his children. He has lived on and successfully cultivated a few acres of land remarked to the present writer—The more I care for and work my land the more it gives me back; my little farm is my bank in which I put my labour and savings, which it pays me back with good interest.' It is often said that thrift, prudence and perseverance are peculiar to the peasant proprietor on the Continent, and are the cause of his success. The history of peasant proprietorship, however, shows that these qualities are the result and not the cause of cultivating ownership, productive habits, early marriages, and little thought for the morrow are the too frequent accompaniments of a condition in which there is no prospect in life beyond that of a mere wage-receiver. The great secret of success of peasant proprietorship is summed up by a British agriculturist: 'All improvements, the most industrious, the most intelligent, and the most successful.' The two great drawbacks of peasant proprietorship are excessive subdivision and the unlimited power of mortgage. The land-lender—whether he is a great estate or a small proprietor who has the right to sell a few acres will submit to any proposition to save money, and will borrow at any rate, in order to acquire more land. The money-lender on the Continent, like the 'goubeem' man in Ireland, is the chief cause of trouble and difficulty to the small cultivator, because the creation of peasant proprietorship in Great Britain, though much discussed, has not till recently been seriously entertained as a practical question. In 1889 the government appointed a Select Committee on Small Holdings, and the evidence contains practical information on the various modes of developing and improving the applicability of the system to Great Britain. The committee in their Report (1890) unanimously recommend that facilities should be given for the creation of small holdings, and they adopt the principles of Mr Jesse Collings' Small Holdings Bill. The general provisions of this bill are as follows: Local authorities are empowered by money's borrowed for that purpose from the state, to acquire land and to sell the same in small holdings not exceeding 60 acres each. Purchasers are required to pay cash a small proportion not exceeding one-fourth or one-fifth of the purchase money. A part of the balance is to be paid off by annual payments, but the remainder—a small proportion of the original cost—is to remain at a perpetual feu or quit-rent. This provision, while it protects the land-lender, removes the money-lender, at the same time makes the terms of purchase as easy as possible. It also enables the local authority to enforce the conditions provided against subletting and subdivision. The local authority is further empowered to let land on favourable conditions in small holdings not exceeding 10 acres each. The report of the Select Committee declares that the extension of small ownerships 'is a matter of national importance both in the interests of the rural population, and
also as adding to the security of property generally.' The committee recommend that a sum not exceeding in the first instance five millions sterling should be devoted to the experiment, and 'earnestly hope that no time will be lost in introducing legislation to give effect to their recommendations.' This report, followed by the announcement of legislation on the subject in the Queen's speech of 1890, and the acceptance by the government in 1891 of the second reading of the Small Holdings Bill referred to, may together be taken as the first practical steps towards the creation of a peasant proprietorship in Great Britain.

See, besides the reports cited above, that from H.M. representatives abroad, On the Tenure of Land in the several Countries in Europe (1869); Loveloy's works on the rural economy of Belgium (new ed. 1875) and the Netherlands (1864); Laverger, Économie Rurale de la France (4th ed. 1877); and W. T. Thornton's Plea for Peasant Proprietors (new ed. 1874).

Peasant War (Bauernkrieg), a great insurrection of the German peasantry which broke out in the beginning of the year 1525. The oppression of the peasants gradually increased, as the nobility became more extravagant and the clergy more sensual and degenerate. The example of Switzerland encouraged the hope of success, and from 1431 to 1517 there were risings amongst the peasants and the towns. A peasant rebellion took place in the Rhine counties in 1502, and another in Würtemberg, in 1514, both of which were put down without any abatement of grievances. The Reformation, by stirring up the desire of freedom, must be reckoned amongst the causes of the great insurrection, although Luther, Melancthon, and the other leading reformers, whilst urging the nobles to justice and humanity, strongly reproved the violent proceedings of the peasants. The Anabaptists, however, encouraged them, and peasant insurrections, quickly suppressed, took place in 1522 and 1523. In January 1525 the peasantry of the abbacy of Kempen suddenly assailed and plundered the convent. This proved the signal for a rising of the peasants throughout the south of Germany. Many of the princes and nobles at first regarded the insurrection as disorder and not as a national demand; it was directed in the first instance chiefly against the ecclesiastical lords; some, too, because it seemed to set bounds to the increase of Austrian power. But the Archduke Ferdinand hastened to raise an army of north-western Germany. Von Waldburg, a man of stern and unsparing character. Von Waldburg defeated and destroyed some large bodies of peasants, but was himself defeated by them on the 22d of April. Meanwhile the insurrection extended, and a number of towns took part in it, as Heilbronn, Mühlhausen, Fulda, Frankfurt, &c., but there was a total want of organisation and co-operation. On 25th March 1525 there appeared in Upper Swabia a manifesto, in which the insurgents demanded the free election of their representatives, the maintenance of the parishes, after maintenance of the parish clergy, to the support of the poor; the abolition of serfdom; the restoration to the community of forests, fields, and meadows which the secular and ecclesiastical lords had appropriated; release from arbitrary augmentation and confiscation of seigneurial duties, and rents; the equal administration of justice; and the abolition of some of the most odious exactions of the clergy. The conduct of the insurgents was not, however, in accordance with these moderation of their demands. They were separated at Rothenburg, destroyed villages and castles (more than 1000 in all), murdered, pillaged, and were guilty of the greatest excesses. A number of princes and knights concluded treaties with the peasants, conceding their principal demands. The regent of Marienberg, near Würzburg, gave time to their enemies to support them with their forces. Götz von Berlichingen (q.v.) was one of the captains of the besieging peasants, who, however, afterwards maintained, had forced him to lead them. In May and June 1525 the peasants sustained a number of severe disasters, and the Landgrave Philip of Hesse, the Saxon Dukes, the electors of the Palatinate and Treves, and Frundsberg were successful farther north. The peasants were everywhere treated with terrible cruelty; more than 300,000 were killed in Upper Germany alone. Multitudes were burned in the streets, and many were put to death with the greatest tortures. Würzburg and other towns which had joined them suffered the terrible revenge of the victors. It is supposed that more than 150,000 persons lost their lives in the Peasant War. Flourishing and populous districts were desolated. The lot of the defeated insurgents became harder than ever, and many burdens of the peasantry originated at this period. The cause of the Reformation and of German national life also was very injuriously affected. Similar peasant insurrections in other countries are treated of under TYLER, CADE, KET, JACQUERE, SPARTACUS.

See works by Jörg (1831), Cornelius (1861), Baumann (1877), Fries (1883), Hartfelder (1884; 2d ed. 1899); the histories of Germany; and works cited at LUTHE, &c.

Peatstone, or Pisolite, a coarse variety of Oolite (q.v.).

Peat, a substance formed by the decomposition of plants amidst much moisture, and to a certain extent, muds, and morasses, and sometimes described as a kind of humus or soil, formed by the accumulation of the remains of mosses and other marsh-plants. The remains of the plants are often so well preserved in it that the species can be easily distinguished. Reeds, rushes, and other aquatic plants may usually be traced in peat, and stems of heart are often abundant in it; but it chiefly consists in the northern parts of the world of different species of Sphagnum or Bog-moss (see Bog-plants). Mosses of this genus grow in very wet situations, and throw out new shoots in the spring. As their upper parts are decaying and being transformed into peat; so that shallow pools are gradually changed into bogs. Stools and trunks of trees often occur under peat in the British Islands and some general remarks may be made upon this subject. Mosses are so abundant, that similar stools and trunks frequently are met with occupying a middle position in many peat-bogs—i.e. resting on peat and covered by a variable thickness of the same accumulation. It cannot be doubted that the overturning of trees, whether by natural causes or by man's hand, would in many cases impede surface drainage, and so eventually give rise to the formation of bogs. But there is reason to suspect that the succession of 'buried forests' and peat so frequently seen in the bogs of northern Europe, is due to slow changes (see Post-glacial System). Peat is vegetable matter more or less decomposed, and passes by insensible degrees into Lignite (q.v.). The less perfectly decomposed peat is generally of a brown colour; that which is more perfectly decomposed is often nearly black. Most peat possesses a decided and powerful antiseptic property, which is attributed to the presence of gallic acid and tannin, and is manifested in the perfect preservation not only of ancient trees and of leaves, fruits, &c., but sometimes even of human bodies. Instances human bodies have been found perfectly preserved in peat after the lapse of centuries.

The formation of peat takes place only in the colder parts of the world. In warm regions the
decay of vegetable substances after life has ceased is too rapid. The surface covered by peat is very extensive. In England it is considerable; it is greater in Scotland, and very great in Ireland. Some large peat-bogs occur in the south of Europe, even near the sea, and in more northern regions the masses or bogs are still more extensive; they occur also in the United States, but more extensively in Canada and Newfoundland. For their physical characters and the mode of reclaiming them, see Bog, and Waste LANDS. Mere peat is not a good soil, even when sufficiently drained, but by the application of lime, manure, &c., it is soon converted into a valuable land, yielding excellent crops. A mixture of peat is often of benefit to soils otherwise poor; and for many shrubs, as rhododendrons, kalmias, whorled berries, &c., no soil is so suitable as one largely composed of peat.

Peat is the ordinary fuel of great part of Ireland, and is still much in request in the hillier parts of Scotland and England. In Holland, Denmark, and parts of north Germany it is in use for the same purpose. Peat is a light and bulky kind of fuel, and cannot be carried considerable distances without too great expense. Efforts have, however, been made to render it more generally useful, and to promote the reclaiming of bogs, by compressing it until its specific gravity is nearly equal to that of coal. For this purpose it is first reduced to a pulp, but the process has not yet been advantageously prosecuted on an extensive scale, though numerous machines for the purpose have been patented in Germany and in the United States.

Peat charcoal, made from uncompressed peat, is very light and incombustible, and therefore unsuitable for many purposes, but for others it is particularly adapted, and no kind of charcoal excels it in antiseptic and desorilizing properties. Peat charcoal is highly esteemed for the smelting of iron and for working and tempering the finer kinds of cutlery. Charcoal made from compressed peat is in density superior to wood charcoal, and is capable of being used as coke. But the conversion of peat into charcoal has not proved remunerative; and the attempts to obtain valuable products (pyroxylic acid, ammonia, inflammable oils, &c.,) from it, and from its destructive distillation have been similarly unsuccessful.

Peat, specially prepared, is very serviceable for horses' bedding, &c. As antiseptic, it has been used for laying on wounds. Flower pots are sometimes made of it; it is easy to transplant plant roots growing in them without loosening the earth from the roots, the pot being readily cut to pieces; and liquid manure applied outside finds its way to the roots.

Pecan. See PASTEsr, Silk.

Pecary (Dicotyles), a genus of the family Sudida, containing at least two species. They have fewer teeth (thirty-eight) than the ordinary swine (forty-four), and a very short tail. The name Dicotyles is derived from a gland upon the back, almost corresponding in position to the navel below. D. trygmat is found from Arkansas to Patagonia, and is about 3 feet long; but the larger and fiercer D. labiates only ranges from Central America to southern Brazil. The latter is exceptionally pugnacious, and, as it goes about commonly in herds, it is extremely dangerous to meet with. Even the jaguar is said to retire before several of these animals when handled together. Both species, which freely breed together, are usually to be seen at the Zoological Gardens in London.

Pechili, Gulf of, a land-locked extension of the Yenisei (q.v.), between the base of the Korean peninsula and the Chinese province of Sian-tung, into which the Pei-ho (q.v.) discharges.

Peck, a measure of capacity for dry goods, such as grain, fruit, &c. It is equivalent to two gallons, and is the fourth part of a bushel; it thus contains in Britain 534.548 cubic inches, and in the United States 537.936 cubic inches. The old Scotch peck of wheat was slightly less than the imperial (British) peck: of barley, about 1450 imperial peck.

Pecock, REGINALD, author of The Expressor of Over-Much Blaming of the Clergy, was most probably born in Wales; was a Fellow of Oriel College, Oxford, in 1417, and was ordained acolyte and sub-deacon in 1420, proceeding to deacon's and priest's orders in the two following years. His preceptors were the mastership of Whittington College, London, together with the rector of St Michael in Holin; the bishopric of St Asaph's, from Duke Humphrey of Gloucester in 1444, when he also received his degree of Doctor of Divinity, and of Chichester, through the patronage of the ill-fated William de la Pole, Duke of Suffolk, in 1450. A student of great learning and industry, he plunged eagerly into the controversies of the day, and compiled many treatises, of which the Bonet (c. 1440), on the main truths of Christianity, and his practical Treatise on Faith (c. 1456), written for the Lollards, are still extant.
PECOS

In the latter he gives up infallible authority in the church, makes faith a matter of probability rather than of knowledge, lays a broad foundation for a really rational piety, and makes a noble approximation to the doctrine of religious toleration. The object in the Pedigree (1456) was to promote the peace of the church by plain arguments against Lollardy, written in the mother-tongue. He main-
tained that bishops had higher duties than mere preaching, and strove with great patience and clear logic to demonstrate the reasonableness of those doctrines and ordinances of the church which the Lollards rejected as not founded on Scripture. Of a liberal and tolerant spirit far before his time, Pecock pointed out with much point and originality the teaching of natural religion about man's moral duties, asserting that the judgment of reason must not be overruled and twisted into conformity with Scripture, which rather confirms than serves as the authority for the light of nature. In his argument that Scripture pre-supposes a knowledge of the moral virtues, and that its special object is to make known those truths which reason could not have discovered, he is distinctly the forerunner of the great Hooker. His attack on the Donation of Constantine is an admirable piece of reasoning, and his argument that experience shows that there is no subject on which men are more likely to err than theological doctrine deals a deadly blow to the bibliolatry of Lollardy and Protestantism. Pecock's philosophic breadth and independence of judgment brought upon him the suspicions of the church, and especially of the friars, whom he had stigmatised as 'pulpit bailiers.' The storm of opposition to which he was gathering burst upon him out of the blue, and he was impeached before the archbishop Bourecher at Lambeth, where his writings were subjected to examination by twenty-four doctors. In the end he was condemned by the archbishop as a heretic whose doctrines were con-
trary to St. Augustine, St. Jerome, and St. Gregory, and the cruel alternative was put before him, to abjure his errors or be burned. He elected to abjure, made confession of many errors and heresies of which he had never been guilty, and with his own hands delivered to the executioner his three folios and eleven volumes; and thus he died; but he did not die in peace. Against the further sentence that he should be deprived of his see he appealed to Rome, and the pope indeed commanded him to be reinstated, but he was prevailed upon to resign his bishoprie into the hands of the king. The rest of his days he spent in the abbey of Thorney in Cambridgeshire. Forty pounds a year was allowed for his mainten-
ance; he was to have the service of an attendant, somewhat liberal diet, and a private chamber with a chimney and a passage leading from it which gave a sight of an altar and allowed him to hear mass. He was denied writing materials, and his books were but five—a breviary, a mass-book, a psalter, a legendary, and a Bible. He died about 1460.

See the article LOLLARDS; also James Gardiner's essays on 'The Lollards,' in Studies in English History (1881); the adduction to Churchill Babington's edition of the Repressor in the Rolls series (2 vols. 1860); and the Life by John Lewis (1774; reprinted, Oxford, 1820).

PECOS, a river of New Mexico and Texas, flows some 800 miles SSE. to the Rio Grande.

PEECTEN. See SCALLOP.

PECULIAR. See BENEFICE.

Peculiar People, a sect of Faith-healers (q.v.), founded in London in 1888. They reject medical aid in cases of disease, although not in surgical cases, and rely on anointing with oil by the elders, and on unceasing prayer, with patient nursing. They have their own collection of hymns, usually select their preachers from among the elders, and baptise their children when they are considered old enough to understand the ceremony and to express consent. Their communities are not numer-
ous, and the members are nearly all very poor working-folk; but they bear a high character for morality, honesty, and Christian charity.

Pedestrianism. See ATHLETIC SPORTS.

Pedicularies, very remarkable minute structures on the skin of sea-urchins and starfish, having the form of a stalk with a three-bladed or two-
bladed snapping forceps at the summit. They take hold of algae preparatory to the application of the se sentorial feet, and probably help likewise to keep the surface of the echinoderm clean.

Pedicularis, a genus of herbs of the natural order Scrophulariaceae, some of which have rather large and finely-
coloured flowers. Two species, P. palustris and P. sylvan-
tica, are natives of Russia and of Britain, common in wet grounds. Both have received the name of Love-wort, the English equivalent of 'pedicularis,' from their supposed influence in produc-
ing the lovesickness in sheep—a notion purely imagin-
ary. Their acridity renders them obnoxious to sheep; but cattle, goats, and swine eat them. Continental herbalists, and the northern parts of Asia produce many other species, and some are found in North America. P. p.p., Love-wort (Pedicularis palustris), trau, or King Charles's Sceptre, is one of the principal ornaments of marshy grounds in the most northern countries of Europe. P. sylvatica is said to be astringent and serviceable in stopping hemorrhage; and applied externally it helps to cleanse ulcers.

Pedigree (possibly from pied de grue, crane's foot), from the slender lines used in drawing pedigrees), a tabular view of the members of a particular family, with the relations in which they stand to each other, accompanied or unaccompanied by a notice of the chief events in the life of each, with their dates, and the evidence of the facts stated. Pedigrees are indispensable aids to the student of history. The materials to be used in the formation of a pedigree are notes of the facts to be set forth, and a ready assistance of signs and abbrevi-
ations. These notes comprise the name of every person who is to appear in the pedigree, with such dates and circumstances as it may be considered desirable to record. Among the commonest abbrevi-
ations are: d., deceased; dwd., deceased; m.,母; w., wife of; s., son; d., daughter of; k., king; e., earl; &c. The sign = placed between:

PECOS PEDIIGREE

5
two names indicates that they were husband and wife; symbols indicate that they had children; \( \downarrow \) under a name signifies that the person had children. Men are frequently indicated by small squares, women by circles or lozenges. All persons of the same sex are arranged in their order of birth in two groups—the sons first, and then the daughters; but where the same father or mother has children by more than one marriage, the children of each marriage ought to form distinct groups. The actual arrangement, however, of a pedigree must always depend on the leading object which it is intended to illustrate. Specimens may be seen in the articles Bonaparte and Bourbon.

Tabular genealogies, generally brief, and meant to illustrate some particular family group of either a royal, public or private, of the early middle ages; but after the incorporation of the English Heralds' College far more attention was devoted to the compilation of pedigrees of families, more particularly with reference to their early heraldry and bravery. In the course of the 16th century the heralds obtained copies of all such accounts of the English families of any distinction as could be supplied to them, and entered them in the books which contain the records of their official proceedings. Royal commissions were issued till 1704 to the two provincial kings of arms, empowering them to visit in turn the several counties of England, in order to collect from the principal persons of each county an account of the changes which had taken place in their respective families in the interval since the last proceeding visitation, and to inquire what account could be given of themselves by families who had stepped into the rank of gentry, or had become settled in the county since that period. The register books kept by the heralds and their assistants contain the pedigrees collected in the course of the visitations, with the signatures of the heads of the families. See HERALDRY, Vol. V., p. 600.

In Scotland, in the absence of the regular system of the English heralds, the Scottish heralds, holding a great deal of evidence regarding the pedigrees of the historical families of the country scattered here and there in public and private collections, including the Advocates' Library and Lyon Office. A register of genealogies exists in the Lyon Office, in which the pedigrees of applicants, after being proved to the satisfaction of the heraldic authorities, are inserted with the accompanying evidence, and the Register of Arms contains much valuable information. To what extent the register of genealogies contains the pedigrees of the families of Scotland is not ascertained. The most probable document, conclusive of the facts which it sets forth, has not been ascertained by actual decision; but there can be no doubt that, in questions both as to property and honours, it would be regarded as the most important and authentic of proof.

Burnett, Popular Genealogist, or the Art of Pedigree-making (Edin., 1865); Rye, Records and Record Searching (1888); Whitham, The Alphabetical Peerage (1853-56); Durrer, Bibliographia Genealogica Americana (1898).

Pediment, the triangular space over the portals at the ends of the roof of classical buildings. It may be called the gable of classical buildings, and is frequently enriched with sculpture, for which it forms a fine setting. See GREEK ARCHITECTURE.

Pedlers. See Hawkers.

Pedometer, an instrument for measuring walking. It has been used for centuries in the revolutions of the mechanism; and the mechanism is generally actuated by the relative movement of a comparatively heavy suspended mass attendant on each step, though in some forms it is driven by a cord connected with the foot. In all cases the walking movement is the number of steps rather than the distance walked; and the user must find the true meaning of the readings of the apparatus as applied to his own walking. An instrument attached to the wheel of a carriage so as to mark the number of revolutions of the wheel and so the distance traversed is called hodometer or odometer (Gr. ἡδος, 'way,' and μετρειν, 'measure'). This is usually a train of wheelwork attached to the axle of the carriage, and communicating motion to an index on a dial. A similar instrument, called a velocimeter, is attached to bicycles and tricycles. The name velocimeter is also applied to a wheeled apparatus, by surveyors, which records the distances in miles or rods.

Pedro I., emperor of Brazil (1798-1822), second son of John VI. of Portugal, fled to Brazil with his parents on Napoleon's invasion of Portugal, and became prince-regent of Brazil on his father's return to Portugal. For the proclamation of Brazilian independence and subsequent history, see BRAZIL. —Pedro II., his son, born 2d December 1825, became king in 1831 on his father's abdication, was declared of age in 1840, and, distinguished by his his kindness and leniency, ruled Brazil in peace until the sudden revolution of November 15, 1889, compelled him to withdraw to Europe, where he lived, mainly in France, Brazil becoming a republic under the name of United States of Brazil. He died at Paris, 5th December 1891. See Life by Moss (1892).

Pedro the Cruel, king of Castile and Leon, was the only legitimate son of Alfonso XI., and was born at Burgos, 30th August 1334. On his father's death (1350) Pedro succeeded to the throne without opposition, but left the whole exercise of power to his mother, Donna Maria of Portugal, and Albuquerque, his prince-minister and chamberlain. He reigned over Brazil in peace until the sudden revolution of November 15, 1889, compelled him to withdraw to Europe, where he lived, mainly in France, Brazil becoming a republic under the name of United States of Brazil. He died at Paris, 5th December 1891. See Life by Moss (1892).

Pedra, mountain range in Italy, forming the northern boundary of the Umbria region.
PEEL

people were in general well and justly governed, but the heavy taxes imposed to maintain the cost of his long wars with Aragon and Granada dissipated his popularity. Henry, who had fled to France, came back to Portugal, the Spanish boundaries, returned (1366) at the head of a body of exiles, backed by Bertrand du Guesclin (q.v.) with an army of mercenaries, and aided by Aragon, France, and the pope. Pedro, however, by great promises of territory and money, prevailed upon Edward, the prince black Prince, to suspend his extremity, and whilst Edward invaded Castile in the spring of 1367, totally defeated Henry and Du Guesclin at Navarrate (13th April), taking the latter prisoner. But the king disregusted his chivalrous ally by his cruelty to the vanquished, and paid no heed to his remonstrances; Edward accordingly repassed the Pyrenees, and left the misguided monarch to his fate. The whole kingdom groaned under his cruelties; rebellions broke out everywhere; and, in autumn 1367, Henry returned with 400 lances, the people immediately flocking to his standard. Pedro's scanty and ill-disciplined forces, including many Saracens, were routed at Montiel (14th March 1369), and himself compelled to retire for safety within the town, whence he was treacherously decoyed and captured by Du Guesclin. He was carried to Bayonne, and the two crowned monarchs, placed between him and Henry, in which Pedro was slain, 23rd March 1369. See Prosper Mérimée's monograph (1848; 2d ed. 1863; Eng. trans. 1849).

Peduncle. See FLOWER.

Peel, a county town of the Isle of Man, 111 miles by rail NW. of Douglas. On Peel Hill (450 feet) is a tower called Corrin's Folly; and on an island sheltering the harbour stand the beautiful ruins of Peel Castle, celebrated by both Scott and Wordsworth. It dates from the 12th century, but was mainly rebuilt from a foundation by Sir Thomas peel, Bishop of Durham, on 5th February 1798, near Bury in Lancashire. His father, Sir Robert Peel (1750-1830), created a baronet in 1806, was a wealthy cotton-spinner, from whom he inherited a great fortune. He was educated at Harrow, and at Christ Church, Oxford, where he took a double first in 1808, and entered the House of Commons in 1809 as member for Cashel, adopting the strong Tory politics of his father. Peel was then prime-minister. Peel set quietly about the business-work of the House, feeling his way with that steady prudence and persevering diligence that were the conspicuous features of his character. In 1811 he was appointed Under-secretary for the Colonies; and from 1812 to 1818 he held the office of Secretary for Ireland. In this capacity he displayed a strong anti-Catholic spirit (whence the witty Irish gave him the nickname of Orange Peel) and was in constant fear of being attacked by O'Connell that even the cool and cautious Secretary was swung into sending the agitator a challenge. The police, however, prevented the duel from taking place. From 1818 till 1822 Peel remained in the office of foreign secretary, where he sat for the university of Oxford. He now began to acquire a reputation as a financier and economist, and in 1819 was appointed chairman of the Bank Committee, and moved the resolutions which led to the resumption of cash-payments. He was still as avers as ever to anything like religious or political reform. No member of the Liverpool-Castleleach cabinet could have been to appearance more respectable; he even vehemently defended the Peterloo massacre. But as he re-entered the ministry as Home Secretary, Peel's troubles, often considerable, on which Canning was considerably in advance of his brother-secretary; and when the former was called upon by the king, after the resignation of Lord Liverpool, to form a sort of Whig-Tory ministry, Peel, along with the Duke of Wellington and others, withdrew from office. Yet it is singularly characteristic of this most honest statesman that even when he succeeded (1827) his opinions were veering round to the liberal and generous view of the claims of Roman Catholics; and when the death of Canning, shortly after, led to the formation of the Wellington-Peel government, its great measure—actually introduced by 'Orange Peel' himself—was the ever-rememberable one for the 'relief' of the Roman Catholics (1829). As Home Secretary he also signified himself by a reorganisation of the police and by his famous Act (sometimes called 'Peelers' and 'Bobbies'), and by the introduction of several other important measures. Meanwhile, the university of Oxford had rejected his upstart representative, and chosen in his stead Sir Harry Inglis. And now came on the odious question of parliamentary reform, on which Peel firmly but temperately opposed. In 1830 the Wellington-Peel ministry fell, and was succeeded by a Whig ministry under Earl Grey, which, in 1832, carried the Reform Bill. Peel (now, by the
death of his father, Sir Robert Peel), when he saw that reform was inevitable, accepted defeat and its results with great equanimity. He shrank from anything like fanatical opposition to the measure, and contented himself with vindicating it scrupulously as an experiment in political per centre. After it was passed he became the leader of the 'Conservative' opposition; and, as we have said, accepting reform itself as a fait accompli and irresistible, he only sought by a keen and vigilant criticism of Whig measures to retard the (too rapid) strides of liberalism.

In 1833, when the first reformed parliament assembled, Peel took his seat as member for Tamworth, which he represented till the close of his life. On the retirement of the Melbourne ministry in November 1834 he accepted almost of prime minister, but could not succeed in giving stability to his administration; he was compelled again to give place to Viscount Melbourne in April 1835, and resumed his place as leader of the opposition. Peel's conduct in opposition was always eminently patriotic. The Whigs, who were being pressed on the one side by the new Radical party and the Anti-corn-law League, and on the other by O'Connell and the Irish repealers, gradually lost ground, and, being all but defeated in 1841 on a motion of want of confidence, dissolved parliament early in 1843. The Irish repealers were virtually a contest between Free Trade and Protection. Protection won; and, when the new parliament met, a vote of no confidence was carried by a majority of ninety-one.

The Conservative party, headed by Peel, now came into office. The great feature of the new government was the attitude it adopted on the corn-law question. The Whigs, while in office, and even after their expulsion, were bent upon a fixed but moderate duty on foreign corn; the Anti-corn-law League would bear of nothing short of an entire repeal, while Sir Robert was in favour of a modification of the sliding-scale of duty which had existed since 1828. He introduced and carried (1842), in spite of strong opposition, a measure based upon this principle. The deficit in the revenue, which had become a crying evil under the Melbourne administration, next engaged his attention, and led him to bring in a bill (1842) for the imposition of an 'income-tax' of 7d. in the pound, to be levied for three years. To alleviate the distress caused by the revolution of the general tariff, and other abolished or lowered the duties on several very important articles of commerce, such as drugs, dyewoods, cattle, sheep, pigs, salted meat, butter, eggs, cheese, and lamb. He also secured himself respite in the repression of the malcontents of Ireland. O'Connell (q.v.) was tried for conspiracy, and, though the judgment against him was set aside on appeal to the House of Lords, the influence of the ‘agitator’ was broken. The first half of 1845 was marked by the alleged Maynooth being increased and changed into a permanent endowment instead of an annual grant, and by the foundation of the Irish unsectarian colleges, and other important measures. But the potato-riot in Ireland during the autumn, followed by a frightful famine, rendered 'cons' necessary. If millions were not starved, Colenso and the others resounding under their exertions. Lord John Russell announced the views of the Whig party on the crisis, and Peel again yielded. He told his ministerial colleagues that the issue was now decided, and that their repeal was inevitable. Some of them refused to go along with him, he resigned, but after a few days was recalled, and resumed office. Lord Stanley (afterwards Earl of Derby) succeeded, and, with Lord George Bentinck, Darnall (whose savage attacks goaded Peel into sending him a challenge), and others, formed a 'no-surrender' Tory party; but the Duke of Wellington, Graham, Abercrombie, and other eminent Conservatives stood by him, and the measure for the repeal was carried. He was, however, overthrown in the autumn and retired from office in June 1846, giving place to a Whig administration under Lord John Russell, to which he gave an independent but general support as the leader of a middle party rather Whig than Tory. In the critical months of 1844-45 he was one of the most important props of the government, whose free-trade principles he had now completely accepted. His ecclesiastical policy had also undergone a remarkable change, and he now frankly supported the Whigs in the efforts to carry an act for the repeal of the Jewish disabilities. He was himself regarded by the working and middle classes generally with much grateful respect. He had a keen English interest in sport, and a cultivated taste in matters literary and artistic. An accident put an end to his career. On the 28th of June 1844 he was riding with some friends near Lord Palmerston in the Don Pacifico matter; but on the following day he was thrown from his horse near Hyde Park Corner, and was so much injured that he died on the night of the 2d of July. He was buried in the church of Drayton Bassett, his Staffordshire home.

See Sir Robert Peel from his Private Papers, edited by C. S. Parker (3 vols. 1891-99), his Memoirs (2 vols. 1857), his Speeches (5 vols. 1856 and 1853); monographs on Peel by Guizot (1851), Laurence Peel, Lord Haldane, Baring, F. C. W. Smith, (1888), John McCarthy (1891), J. R. Southwood (1891), Shaw Levete, Peel and O'Connell (1887); Greville's Memoirs; Beaconsfield's Bentinck; Morley's Cobden; Froude's Beaconsfield (1890); Croker's Memoirs, Diaries, and Correspondence (1884); also Corn Laws, Catholic Emancipation.

Peel left five sons, the eldest of whom, Sir Robert, and the second, Sir Frederick, have both held office as ministers; whilst Arthur Wellesley, the youngest (born 1829), became Speaker of the House of Commons.

Peel, or Peel-tower, the name given to fortified towers or small castles of the type common on the Scottish border. In the 13th and 14th centuries the word 'peel' was used to denote the earthen works, surmounted by palisades, which surrounded and defended the courtyard and tower; but later on the name was applied to the tower itself. See Borders, Castle.

Peele, George, an Elizabethan dramatist, was son of James Peele, Clerk of Christ's Hospital, and was born most probably about 1558. He had his education there, and went up to Oxford in 1571. Next year his name is found on the list of members of Broughton Hall, now Lambrook College, and from December 1574 to 1579 he was a student of Christ Church. He took his bachelor's degree in 1577, his master's in 1579. He seems to have had a reputation at the university as a poet and raconteur; in his satirical pages, but by 1581 he had removed to London, where he lived a roystering Bohemian life as actor, poet, and playwright, dying a disreputable death in 1598. 'As Amerson died by the pot, so George Peele by the pan,' writes Meres. We know that he married in 1588, and was very near to those warned to repentance by the miserable Grocas in Grapesworth of Wit bought with a Million of Repentance (1592). Little confidence need be put in The Merry Jests of George Peele (1607), which are
PEEP O' DAY BOYS

mostly ancient and borrowed witticisms, representing Peele as a shifty and disreputable trickster and vagabond haunter of taverns. His best work, The Arraignment of Paris, a dramatic pastoral containing the revised version of the sonnets of Elizabeth, was published anonymously in 1584. Another pastoral play, The Hunting of Cupid (1591), is lost. In 1585 he was employed to write the Lord Mayor Dixi's Pageant, and in 1591 he prepared another for the mayoralty of Sir Willy, which is in Sir Henry Jortin's revised text to Sir John Norris in his expedition to Portugal in 1599 (cked out by A Tale of Troy); his Elegies Gravulatatory (1589) to the Earl of Essex on his return; his Polyphonica (1600), on the retirement of Sir Henry Lee from the office of queen's champion (closing with the exquisite song 'His golden locks time hath to silver turn'd,' quoted in The Newcomes); his Speeches for the reception of Queen Elizabeth on her visit (1591) to Burgsley at Theobalds; and his Honour of the Garter, written on the occasion of the investiture of the Earl of Northumberland and Worcester (1593), are other examples of the occasional poems that flowed from his fluent pen, and helped him to make a shifty living.

The historical play of Edward I. (1593) has descended in a very corrupt text, and is grievously marred by its baseless slanders against the stainless Queen Eleanor, due to the anti-Spanish prejudice of the time. His bombastic and ranting play, The Battle of Alcæus, was published anonymously in 1594, and was followed by another now lost, which is in Sir Henry Jortin's revised text to Sir John Norris in his expedition to Portugal in 1599.

In the reign of Elizabeth, he visited the Dutch Republic, and wrote a dramatic poem in imitation of Polyphonica (1600), on the retirement of Sir Henry Lee from the office of queen's champion (closing with the exquisite song 'His golden locks time hath to silver turn'd,' quoted in The Newcomes); his Speeches for the reception of Queen Elizabeth on her visit (1591) to Burgsley at Theobalds; and his Honour of the Garter, written on the occasion of the investiture of the Earl of Northumberland and Worcester (1593), are other examples of the occasional poems that flowed from his fluent pen, and helped him to make a shifty living.

The historical play of Edward I. (1593) has descended in a very corrupt text, and is grievously marred by its baseless slanders against the stainless Queen Eleanor, due to the anti-Spanish prejudice of the time. His bombastic and ranting play, The Battle of Alcæus, was published anonymously in 1594, and was followed by another now lost, which is in Sir Henry Jortin's revised text to Sir John Norris in his expedition to Portugal in 1599. His charming play, The Old Wives' Tale (1596), which most probably gave Milton the subject for his Comus, is well defended by Mr Bulwen from the groundless criticisms of Symonds and Saintsbury. The latter, however, finds much higher poetic merit in David and Bethsabe (1599) than either Mr Bulwen or Charles Lamb. The last work assigned to Peele is Sir Clymene and Sir Chemence (1599), but its authorship is more than doubtful.

Peele's works were first collected by Dyce (2 vols. 1838; 2d ed. 1839; a supplementary 3d volume in 1839). A carefully revised re-issue was published, together with Greene, in 1885, and a revised edition is that of H. H. Bulwen (2 vols. 1888). See Ward's English Dramatic Literature (1875), and J. A. Symonds's Shakespeare's Predecessors (1884).

PEEP O' DAY BOYS, an Ulster Protestant association (1780-95).

PEEPUL, or PIPAL (Ficus religiosa), also known as the SACRED FIG of India, and in Ceylon called the BO-TREE, a species of Fig (q.v.), somewhat resembling the Banyan, but the branches not rooting like those of that tree, and the leaves heart-shaped with long attenuated points. The tree is held sacred by the Hindus, because Vishnu is said to have been born under it. It is generally planted near temples, and religious duties spend their lives under its shade. It is also held sacred by the Buddhists of Ceylon (see BO-TREE). It attains a great size and age. The peepul is often planted near houses, and by the sides of walks, for the sake of its grateful shade. The juice contains a kind of gum, and is used by women and bandoline. Loc-insects feed upon this tree, and much lac is obtained from it. The fruit is not much larger than a grape, and although edible is not valued.

Peeage. See Nobility, Parliament.

Peevit. See Lapwing.

PEGASUS, in Greek Mythology, a winged horse which arose with Chrysoroi from the blood of the Gorgon Medusa, when she was slain by Perseus. He is said to have received his name because he first made his appearance beside the springs (pégaí) of Oceanus. He afterwards ascended to heaven to carry the thunder and lightning of Zeus. Some later authors make him the horse of Eos. Bellerophon had in vain sought to catch Pegasus for his combat with the Chimaira, but at length was advised by the seer Polydorus of Corinth to sleep in the temple of Minerva. The goddess appeared to him in his sleep, and gave him a golden bridle with which he caught him, and by his aid overcame the Chimaira. Modern writers ignorant of mythology make Pegasus the horse of the Muses, with whom, however, he had nothing to do beyond having by a kick of his hoof made spring up the inspiring fountain of Hippocrene.

Pegmatite, a variety of Granite (q.v.).

PEGU, a town, division, and river of Lower Burma. The town stands on the river Pegu, 46 miles N.E. of Rangoon. The old city was founded in 573 and was made the capital of a powerful independent kingdom. European travellers in the 16th century speak of its great size and magnificence. It was destroyed in the middle of the 18th century by Alompra; but was rebuilt. A celebrated pagoda still stands within part of the old walls. The place was handed over to the British by the inhabitants both in the first and the second Burmese war. Pop. 10,762. - The division has an area of 9160 sq. m. and a pop. (1891) of 1,456,489. - The river rises in the Pegu Yoma Mountains, and flows generally south for 180 miles, joining the Rangoon or Hingin River.

PELEHLY, an ancient West-Indian (Median and Persian) idiom, in use chiefly during the period of the Sassanides (235-640 A.D.). See Persia, Zend.

PELI-NO, a river of China, rises near the borders of Mongolia, flows north-east and south-east, past Peking and Tsien-tsin, and falls into the Gulf of Pe-chi-li after a course of more than 350 miles. The mouth of the river is defended by the powerful forts of Taku (q.v.). See China.

PÉNÉLOPE. See Peire, Pénélope.

PÉNÉLOPE, in Greek Mythology, a winged horse which arose with Chrysoroi from the blood of the
prevailed, which had no sanction from the law, of
the effect of tying the thumbs tightly together with
whipcord, that the pain might induce the offender to plead. Among instances of
the infliction of the pume forte et dure are the following: Juliana Quick, in 1442, charged
with her husband in speaking contemptuously of Her
Majority, 'the master of York', in 1588, for her constancy to the Catholic faith; Walter
Calverly of Calverly, in Yorkshire, arraigned at the
York assizes in 1665, for murdering his two children
and stabbing his wife; and Major Strangways, in
Northumberland in 1757, for refusing to hold when charged
with the murder of his brother-in-law. In 1720
a person of the name of Phillips was pressed in New-
gate for a considerable time, till he was released
on his submission; and the same is recorded in the
following year of one Nathaniel Hawes, who lay
under a weight of 250 lb. for seven minutes. As late
as 1741 a person is said to have been pressed to death
at the Cambridge assizes, the tying of his thumbs
having been first tried without effect. A statute
of 1772 virtually abolished the pume forte et dure, but
preserved that any person who shall stand mute
when arraigned for felony or piracy shall be con-
victed, and have the same judgment and execution
awarded against him as if he had been convicted
by verdict or confession. A later statute (1828)
made standing mute equal to a plea of 'not
guilty.'

PEIPUS, LAKE, in the north-west of Russia,
lies between the government of St Petersburg
and the province of Livonia. On the south it is con-
ected with Lake Pakoff by a long, narrow channel,
the length of both lakes being 57 miles, the greatest
breadth about 30, the area 1356 sq. m., and the
depth from 14 to 40 ft. The waters, which
abound in fish, are carried to the Gulf of Finland
by the Narva. The shores are marshy and flat.

PELREE, BENJAMIN, mathematician, was born
at Salem, Massachusetts, 4th April 1800, and
studied at Harvard, where in 1823 he became pro-
fessor. In 1849 he became consulting astronomer
in the American Nautical Almanac; and from
1857 to 1874 he was superintendent of the Coast
Survey. In 1856-46 he issued an admirable series of
mathematical text-books, and he contributed to
various mathematical journals. His paper on
the discovery of Neptune (1848) attracted universal
attention; and his papers on the constitution of
Saturn's rings (1851-55) were equally remarkable.
His great Treatise on Analytic Mechanics appeared
in 1857; and he left his mark on various depart-
ments of mathematical and astronomical investiga-
tion. He died at Cambridge, 6th October 1889.

PELISHWA. See MAHRATTAS.

PEKANU or WOOD-SNOUT (Martes pennanti),
an American species of Marten (c. v.), the largest
of all the species, was formerly common in North
America from Alaska and the Slave Lake into the
central United States, but is now extinct in settled
districts. There seems to be nothing in its habits
to justify its common name of Fisher or Fisher
Marten; but hunters it is called the Wood
Fisher.

PEKIN, capital of Tzaytow county, Illinois, on
the Illinois River, 10 miles by rail S. of Peoria.
It has several foundries, flour-mills, distilleries,
and manufactories of organs, ploughs, wagons, &c.
(Pop. (1860) 8429).

PEKING, or, as now often pronounced, PEKI-
CHOW, Tientsin (on the Northern Capital), the capital of the
Chinese empire, is in 39° 54' 36" N. lat. and 116°
37' E. long. It is situated in a sandy plain, and
is surrounded by many gated walls, with suburbs
smaller than most other large cities in the country.
The visitor coming to it from Tien-tsin is not
prepared for his approach to it by villas and
mansions with their parks and gardens, such as
greet him in drawing near to the capitals of
the West. At a turn in the road the city bursts at
once on his view, standing up grand and grim,
complete in itself with its lofty walls, and
the loitering towers upon them. The city consists,
in fact, of two cities—the Inner and the Outer—known
also as the Manchu or Tartar and the Chinese,
the Northern and the Southern. They are separated
by a high wall common to them both, but properly
belonging to the former, and giving it the appear-
ance of nearly a square, on which the other partly
rests in the form of a rectangle, its southern and
northern walls longer than those of the square, but
the other two shorter. The walls of the Manchu
city average 50 feet in height, and are fully 60 feet
wide at the bottom and 40 at the top; the dimen-
sions of those of the Chinese city are less—30 feet
in height and 25 and 15 in width. Those of the
former measure 144 miles in circuit, including
its part of the cross-wall, and those of the Chinese
city 10. Not counting the cross-wall, the whole
circuit measures about 21 miles, including al-
together an area of nearly 26 sq. m. In all
Peking has sixteen gates. Over each is raised a
tower about 100 feet high, and of very imposing
appearance. All the gates of the Manchu city are

Guarded by semicircular arcades, enclosing a
yellow-tiled temple to Kwan Ti, a hero of our 21st
century, now honoured as the 'God of War.'

When a stranger has entered by a gate of the
Northern City, and rides or drives along the cross-
wall to its central gate, he is greatly impressed by
the magnificence of the walls and towers, and
readily believes Peking is the grandest city in the
world. Such was the feeling of the writer when he
entered it in 1873; after he had passed through the
gate, there stretched before him, as far as his
eye could reach, a street about 200 feet across,
lined with what seemed to be brilliant shops on
each side, with wide spaces for foot-passengers,
and between them a carriage-way, raised about
two feet, on which a constant stream of vehicles,
with horses, mules, camels, and donkeys,
was hurrying. But by-and-by this impression of
the magnificence of the city was displaced by another
of the dilapidation and decay, squalor and filth,
which everywhere obtruded themselves.

Peking is one of the most ancient cities of the
world. On the same site stood the metropolis of
the feudal state of Yin, whose history is traceable
back to the 12th century B.C. In our 10th and
12th centuries two Tartar tribes which attempted

Gateway at Peking.
to impose their sovereignty on the empire made the old metropolis of Yen their capital. The second, which had absorbed the other, fell before the invading Mongols in the 13th century, and Kublai, a grandson of Genghis Khan, enters the chronological line as sovereign of all China in 1280. He made Peking his capital, and there he was found by Marco Polo, who styles the buildings which had absorbed the old 'a vast and excellent city.' It is called the King Shan, loosely translated 'Prospect Hill,' and affords the finest view of the entire city. It is separated from the Forbidden City by a moat, which is crossed by more than one marble bridge. Among the people the common name for it is 'Coal Hill.' Their belief being that it was formed by stores of coal, deposited there by way of provision against a siege. The western portion of the 'August City' goes by the name of the Western Park. A principal attraction in it is an artificial lake more than a mile long, though not nearly so wide, the dam of which is the hills to the west of the city, which served also to supply the moat all round the walls. The lake is crossed by a marble bridge of nine arches, and in the proper season its surface is beautiful with the large, brilliant flowers of the lotus. At the south end of the park are the summer-house, the rock-work, the gardens, and the hall for the examination of military candidates, and at the opposite end the copper statue of Maitreya (the coming Buddha, 60 feet high, with one hundred arms), the temple of the Patent Rice, a temple dedicated to Yuan Fei (2500 B.C.), the discoverer of the uses of the silk-worm, with a plantation of mulberry-trees and a cocoanut-house near it. The empress annually comes here with her ladies to offer sacrifice to this Yuan Fei, to feed the silk-worms, and to unwind some of the cocoons, as an example to the women of the empire.

We now come to the General City. On either side of the avenue leading from the central gate of the cross-wall to the August City are the principal offices of the government—the Ministry of the Censorate. In the same neighbourhood are the observatory, the Provincial Hall for literary examinations, the Colonial Office, and the Han Lin Yuan, which we call the 'National Academy,' and to belong to which is the highest literary distinction in China. Its members are many and of various grades. All the literary work of the government may be said to pass through their hands.

In the north-eastern corner of the city is the Russian mission, and west from it the Yung Ho Kung, or Foreign Temple. It is a great lamastery, where more than a thousand Mongol and Tibetan monks dwell, and are provided for, while they study their religion under the rule of a Geogor, or 'living Buddha.' At the north-west end of the city is the enormous image of Maitreya, 70 feet high. A little farther to the west stands, amidst many cypress, the temple of Confucius, under the ancient name of Kwo-ta-tze Chien. In the lofty hall are the spirit-tablets of the sage and his most celebrated disciples and followers—nothing else. Close by these rises from a cireel of water the Pi Yang Kung, commonly called 'The Hall of the Classics,' from the most remarkable thing about it—182 pillared slabs of granite, reared up in two corridors, and having the text of all the classical books engraved on them, in thick, fine, and braille, formats.

In the western side of the city are the headquarters of the T'ie-tuh, or 'general-in-chief,' who has the control of the police and garrison of the city, and very much directs its civil administration. He resides between the same two temples of both conspicuous objects. Five great bells were cast in the Yung-lo period, early in the 16th century. One of them is here, another about 2 miles in a north-west direction from the city, in 'The Great Bell Temple.' It is indeed a monster, 14 feet high, 34 feet in circumference at the rim, and 9 inches thick, and is said to weigh 120,000
Peking. (See Bell.) It is covered, insidiously, with
myriads of Chinese characters, from *Hieh Hieh* and *Ling Yen*, two Buddhist sutras.

Going towards the south wall, we met great
structures on our way. One is the *Tien Muo*, or Temple of Heaven, where the
reigning emperor goes to worship the spirits of
nearly two hundred sovereigns, who ruled from
Pâ-hâ (at least 3000 years B.C.) to the present
dynasty, and with them are assailed
the spirits of the ablest and best of their
subjects. The temple, which, as an
example of stone industry to all his people,
contains a large structure reserved for
the emperor, his ministers, and court
officials. The usual Chinese plan is
adherent to, the hall and other open courts are
covered with artificial lakes and tanks. Where it is
over, the streets are for the most part narrow,
and the people are busy and hustling. There
are clubs-houses not a few, various temples,
charitable institutions for the poor, the aged, a
few hospitals, in the Inner City; companion
sung the latter is the new Roman Catholic church,
a magnificent structure, completed in 1891.

The Chinese or Outer City is very sparsely populated. Much of the ground is under
vigation, large tracts are wooded, green fields
though the chief and other open spaces are
covered with artificial lakes and tanks. Where it is
over, the streets are for the most part narrow,
and the people are busy and hustling. There
are clubs-houses not a few, various temples,

miserable. The manufacturers are unimportant. The government of the city is distinct from that of the department, and is administered by a superintendent (a high imperial functionary), a mayor, and officers in the several quarters. The police force in the city is very small; some 10,000 soldiers or militia are quartered in the town. The daily Peking Gazette, a pamphlet of sixty to seventy pages, is the imperial official journal. Since 1864 there has been an imperial university with American and European professors.

In the city of Peking, according to some, in the surrounding country; indeed, it exists only in some provinces, four or five in number. The dead-carr is in connection with the founding hospitals, which are established in the Inner and Outer Cities; there take their lives. At present the people are not aware of the existence of infanticide, nor is this abominable custom known in the surrounding country; indeed, it exists only in some provinces, four or five in number. The deaded-cart is in connection with the founding hospitals.

See Rennie's *Peking and the Pekingese* (1865); William's *Journeys in North China*, especially chapter xvi, which the author's brother, Mr. William, translated into Chinese: their Education, Philosophy, and Letters (1881); William's *The Middle Kingdom* (revised ed., 1883); and other works cited under CHINA.

**Pelagius,** a celebrated heresiarcl of the 5th century. He was probably born about the middle of the century in Britain, or according to some, in Avignon, his name being supposed to be a Greek rendering (Pelagios) of the Celtic appellative Morgan ('sea-born'). He was a monk, but he never entered into holy orders. He settled in Rome about 400, where he seems to have been acquainted with the Roman emperors and with their discussions. His views seem to have been early developed; and during his stay in Rome he seems to have given them full expression—especially in his commentaries on the Pauline Epistles, which were published at this time. It has been remarked that his doctrinal tenets, and in a word, his entire mind and views concerning the nature and end of the Eastem Church, and may therefore be taken as showing that Eastern influences were still alive in the Western churches. But more probably his theology was the outcome of his own devout and earnest mind. Jerome and Augustin tell tales to his discredit; but these are refuted by the respect with which Augustin always speaks of his character and conduct. The controversy about Pelagianism was not started by Pelagius, but by a devoted disciple of his. In Rome he had attacked to his views a follower of great energy named Celestius, probably an Irish Scot, originally a lawyer, who was practising in Rome when Pelagius came thither. He became a monk, and accompanied Pelagius wherever he went. In 410, after the sack of the city by the Gothic king, he went to Andrew. After some time Pelagius made a pilgrimage to Jerusalem, where he met St Jerome. Celestius having remained at Carthage, and sought to be admitted to ordination, his doctrines became the subject of discussion, and in a word, several opinions ascribed to him were condemned—proceedings which introduced St Augustine into the controversy. Meanwhile Pelagius remained at Jerusalem, and news of the proceedings at Carthage having been carried to Palestine, in 415 he was accused of heresy before the Synod of Constantinople. As accused by Celestius, his doctrines seem to have been a reaction against Gnosticism, Manicheism, and Fationalism, in the interest as he conceived of a higher morality than
the Augustinian writings in opposition to Pelagians, were some monks of the southern provinces of Gaul, and especially of Marseilles, whence they are usually supposed to have been, the Lutianian, from the Latin name (Molina) of that city. Of these leaders the chief was a priest named Cassian (Joannes Cassianus), who had been a deacon at Constantinople. Of the system which he propounded it may be enough to say that it upheld the sufficiency of grace as natural, but regarded the first act of conversion to God and the initial act of man's repentance for sin. Every man naturally possesses the capacity of beginning the work of self-conversion; but for all ulterior acts, as well as for the completion of justification, grace is indispensable. The Semi-Pelagian doctrine is often confounded with that of the Molinist (see Molina) school of Roman Catholic theology; but there is one essential difference. The latter persistently maintain the necessity of grace for all supernatural acts, even for the beginning of conversion, although they are generally represented as agreeing with the Semi-Pelagians as to the mode of explaining the freedom of the human will acting under the influence of divine grace. The chief writers in the controversy were Prosper, Bishop of Aquitania, and Ambrose of Milan, against whom is referred Celestine, Bishop of Rome in 431. It continued, however, to be agitated in the West for a considerable time. Faustinus, Bishop of Reji (Riez in the Baess Alps), towards the end of the 5th century revived the error, and it was emuluated in a council held at Cambrai in 553, and again in the second council held at Arusino (Orange) in 555, and again in the third council of Valence in 530. The words of Augustine were formally accepted: but the tendency which produced Pelagianism and Semi-Pelagianism has often reappeared. 

Pelargonium, a genus of plants of the natural order Geraniaceae, including many of the most favourite greenhouse flowers, to which the old generic name Geranium is often popularly given. The characters which distinguish pelargonium from geranium, as now restricted by botanists, are given in the article GERANIUM. Their leaves are numerous and mostly native of the Cape of Good Hope, of certain other parts of South Africa, and a few are natives of the Canary Islands. Some of them are herbaceous and some are stemless; most of them are half-shrubby. Some have tuberous root-stocks. The leaves exhibit great variety in form, size, colour, &c. The flowers always adhere to a certain type in form, but with great variety in size, colour, &c.; they are always in stalked umbels, which arise from the axils of the leaves, or on the stems. The kinds from the midst of the leaves. In no genus have the species produced more striking results than in this: and the number of beautiful hybrids and varieties is very great, some of them excelling in beauty any of the original species. Some species not possessing much beauty have been cultivated for the graceful colour of their leaves, which in some resemble that of roses, in others that of apples, lemons, &c. whilst that of many species is rather unpleasant. The cultivation of pelargoniums is similar to that of other Geraniaceae (see GERANIUM). A few of the species require the open air in the south of England; many are planted out in summer even in Scotland. Water must be liberally supplied to pelargoniums during the time of flowering; but no plants more strongly require a period of rest, and water must then be very sparingly given. The shrubby and sub-shrubby kinds are easily increased by cuttings either of the branches or the roots, stout year or the following year after the leaves fit for the purpose. Sandy soil and very moderate supplies of water are requisite till the cuttings are rooted, when richer soil and a more liberal supply of water are needed. The tuberculous-rooted species are increased by cuttings of the roots and by seed.

Pelagians, a term somewhat variously used for certain inhabitants of ancient Greece. In Homer the Pelasgi seem to have been an important tribe living in Thessaly. Herodotus seems to regard the Pelasgi not as Hellenic, but as barbarians who had occupied the Assinian plains at the time of it ere the Hellenes came thither (see Greece, Vol. V. p. 386). Modern students have also interpreted the term differently. Some regard the Pelasgi as the pre-Aryan occupants of Greece, others as the Greek-Italians—i.e. the common ancestors of the Greeks and Italians. The truth is that we know little or nothing of the pre-Aryan occupants of Greece, or of the Gravo-Italians, or of the builders of Cyclopean works, and that there are no reasons for identifying any of them with the insignificant tribe of Pelasgi. Then, Cyclopetan—i.e. a name applied to certain architectural works in Greece, which probably date from between 1000 B.C., and which are unconnected in point of evolution with any style of Greek architecture subsequently developed. The characteristic which distinguishes Cyclopetan from other works of architecture is that it consists of huge polygonal stones, which may or may not be so arranged as to fit into one another without interstices requiring lesser stones to fill them up, but which are always hewn and are always kept in their places not by means of mortar or any other material, but by their own great weight. On the other hand, work of this kind is not necessarily ancient; other considerations than the nature of the work itself are requisite to date it. Nor is it confined to Greece: similar remains are to be found in Egypt, Asia Minor, Sicily, Sardinia, Spain, &c., as well as in Greece and Italy. The most important ancient Cyclopean works in Greece are the walls of Tyrins, Iphippos, and Mycenae, the Lion Gate and so-called Tresorium (graves) of the latter place, and a probable temple on Mount Oetica. The Cyclopetan walls of ancient cities were so thick as to allow galleries to be run lengthwise through them. At Tyrins window-like openings look down from these galleries on to the town. That these galleries served the purposes of fortification in some way is clear, but in what way is not clear. The walls are broken by gates, of which the best known is the celebrated Lion Gate at Mycenae. In this form of doorway, in order to relieve the pressure on the lintel (which rests horizontally on the perpendicular stone doorposts), a triangular space is left above the lintel, and this is the case of the Lion Gate, with a slab, on which are sculptured the figures of two animals (not lions) rampant, one on either side of a pillar. This quadrilateral device is undoubtedly of oriental origin, or imitated from some Asiatic source, nothing as to the origin of the architecture or its builders. The same means for relieving the pressure on the lintel is employed in ancient remains in Cornwall. The Treasuries or tombs are underground chambers in the shape of bee-hives, vaulted with a succession of overlapping stones, and approached by a narrow passage through the side of the hill in which they are situated. The interior was ornamented with plates of bronze attached to the masonry. The term Cyclopetan was applied by the Greeks to this kind of architecture on the strength of the popular
etymology of the term: *cyclopes* = builders of a 'eye', or ring-wall. See CYCLOPES.

**Pelavo**, said to have been the first Christian king of Spain, seems to have made head against the Arabs in Asturias (q.v.) in the 8th century. See SPAIN.

**Pelcsch**, a royal castle of Roumania, built by Doderer of Vienna in 1783-84, in a romantic situation on the south side of the Transylvanian Alps, 70 miles N. of Bucharest.

**Pelew Islands**, also PALAU, a group in the Pacific belonging to Germany, lie south-east of the Philippines, at the western extremity of the Caroline Archipelago, with which they are sometimes classed. There are about twenty-five islands, mountainous, wooded, and surrounded with coral-reefs. Total area, 170 sq. m. The principal is Babelthup or Babeltop. The soil is rich and fertile, and the climate healthy. Bread-fruit, cocoa-nuts, sugar-cane, palms, areca-nuts, yams, &c. are grown. Turtles, tarpang, and fish abound on the coasts. The population is about 20,000 in all. The Plague is prevalent among the Malay race. The men go entirely naked and the women nearly so. They are described as being good-natured, and have peculiar social institutions — the women too. The islands were discovered by the Spanish in 1543, and visited again in 1696. See **Palau**, **Die Palauinseln** (1873); **Kubary, Die sozialen Einrichtungen der Palauer** (1885); and **Marche, Luçon et Palouan** (Paris, 1887).

**Pelham**, the family of, takes its name from a castle and lordship in the north-east of Hereford, and was elevated to the peerage in the person of Sir Thomas Pelham, who in 1706 was created Baron Pelham by William and Mary, and married Lady Grace Holles, sister of the Earl of Clare. His successor, THOMAS PELHAM HOLLES, Duke of Newcastle, and minister of the first two Georges, was born in 1693, and educated at Westminster and Clare Hall, Cambridge. In 1711 he succeeded to the vast estates of his maternal uncle the Duke of Newcastle, and next year to the peerage of his father, the first Lord Pelham. George I. rewarded his services by creating him Earl of Clare (1714) and Duke of Newcastle in Northumberland (1715). He was married twice, first to Elizabeth, Countess of Strathmore and Nottageham, and a Knight of the Garter in 1718, and in the same year he married Lady Henrietta Godolphin, granddaughter of the great Marlborough. In 1724 he succeeded Carteret as Secretary of State, and held the office continuously under all his successors for nearly thirty years, although a man of no particular ability except in parliamentary tactics. In 1754 he succeeded his brother, Henry Pelham, as premier, but retired in November 1756 to give place to the Duke of Devonshire, himself being rewarded with the title of Duke of Newcastle-under-Lyne, with special remainder to the Earl of Lincoln, his niece's husband. In July 1757 he was again premier, and compelled to take the first William Pitt into his ministry and to give him the lead in the House of Commons, and the supreme direction of the war and of foreign affairs. A succession of brilliant victories followed—Newcastle being only nominal head of the administration—and the great commoner had almost brought the war to a successful termination, when the accession of George III. led to the ministry's downfall. He resigned before the rent of Newcastle, in May 1762, by Lord Bute, as head of the ministry. Newcastle declined a preferred pension, with the remark that if he could no longer serve he would not burden his country. In the Rockingham ministry, formed this time for the purpose of toppling the ministry of Privy Seal. He died in Augt. 1768. — His younger brother, HENRY PELHAM (1690-1754), took an active part in supporting the rebellion of 1715, became Secretary of State for War in 1724, and was a zealous supporter of Walpole. In 1743 he was made head of a ministry as First Commissioner of the Treasury and Chancellor of the Exchequer. Events during his ministry were the war of the Austrian succession, the Dutch Rebellions of 1747 and 1756, and the successful financial bill of 1750 (see GEORGE II.), the reform of the calendar, and Lord Hardwick's Marriage Act. His father's ducal title descended to Henry, ninth Earl of Lincoln, whose great-grandson...

**Henry Pelham-Clinton**, fifth Duke of Newcastle, and twelfth Earl of Lincoln, was born 22d May 1811, and educated at Christ Church, Oxford. He represented South Notts in parliament from 1832 to 1846, when he was ousted by the influence of his father, the fourth duke, for supporting Sir Robert Peel in his free-trade measures. He was a Lord of the Treasury in the brief Conservative administration of 1834-35, and First Commissioner of Woods and Forests in the Peel administration, 1841-46. He was then made Irish Secretary, but went out of office with his father a few months afterwards. He succeeded to the dukedom in 1851, and returned to office in 1852, filling the post of Secretary of State for the Colonies in the Aberdeen government. The war with Russia broke out, and in June 1915 he formed a ministry to create a Secretary of State for War, and the new office was assigned to Newcastle. The terrible sufferings of the British army before Sebastopol in the winter months of 1854 raised a storm of popular discontent, and when the House of Commons determined to inquire into the conduct of the war the duke resigned. Newcastle was Colonial Secretary in the second administration of Lord Palmerston, and held the seals with general approval from 1859 till his death, 18th October 1864.

**Pelican** (*Pelecanus*), a genus of birds comprising a family, Pelicanidae, having a very long, large, flattened bill, and the mandible terminated by a strong hook, which curves over the tip of the lower one; beneath the lower mandible a great pouch of naked skin is appended; the tongue is very short, and almost rudimentary; the face and throat are naked, and the bird has a long length, the tail rounded. The species are widely distributed, frequenting the shores of the sea, lakes, and rivers, and feeding chiefly on fish. Although birds of powerful wing, they are seldom seen at a great distance from land. All of them are birds of large size. They take their prey by lowering over the water, and plunging upon it when it appears. They often fly in large flocks, and the sudden sweep of a flock of pelicans at a shoal of fish is a striking and beautiful sight. They store up their prey in their pouch, from which they bring it out as leisure, either for their own eating or to feed their young. The pouch is capable of being wrinkled up into small size, and of being greatly distended. The Common Pelican (*P. onocrotalus*) is as large as a swan, white, slightly tinged with flesh colour, and, in old birds, grey, with red bills, where the bill feathers are black, but are scarcely seen except when the wings are expanded. It is a native of the eastern parts of Europe and of many parts of Asia and Africa, and frequents both the seacoast and also rivers and lakes. It makes a nest of grass on the ground, and lays six or seven white eggs, often on an island, and lays two or three white eggs. The parents are said to carry water to their young, as well as food, in their pouch. During the night the pelican sits with its bill resting on its breast. The rail or hook which extends from the bill is red; and it has been supposed that the failure of the pelican feeding its young with blood from its own breast originated in its habit of pressing the
hill upon the breast in order to make it easier to empty the pouch, when the red tip might be mistaken for blood. Another explanation is that the characteristic has been transferred to the pelican from the flamingo, which does discharge into the mouth of its young a bloody-looking secretion which it discharges (see Notes and Queries, 1862, p. 361). And long since Sir Thomas Browne in *Vulgar Errors* pointed out that the carvings

is so enormous. The fish probably engulfs small animals in whale-like fashion, but at the bottom of the sea instead of at the surface. Gill and Ryder discovered a similar form, *Gastrostomus bairdii*, in 1883, in which the month again suggests a pelican's pouch. The equally strange Saccopharyngide are perhaps allied, but the jaws are less enormous, and the animals are notable for swallowing fishes larger than themselves.

**Pelican**

The ancient name of a wooded mountain-range in Thessaly, extending along the east coast. According to the myth, the Titans, in order to seal Olympus, the abode of the gods, placed Ossa (q.v.) on the summit of Pelion, the highest peak (6,210 feet) of the range. Its sides and summit have always been clothed with forests of oak, chestnut, beech, elm, plane, and pine; it was of Pelion timber that the Argo (see *Argonauts*) was built. The Centaur Chiron had his home on this mountain.

**Péllisson**, Amable Jean Jacques, Duc de Malakoff, Marshal of France, was born 6th November 1794, at Maromme, near Rouen, and, having passed successfully through the colleges of La Fère and St Cyr, entered the army. He served on the staff in Spain in 1823, made the campaign of the Morea in 1828, joined the first expedition to Algeria in 1830 as major of cavalry, and in 1838, with Algeria with the rank of lieutenant-colonel. In 1845 he acquired an unenviable notoriety by slaughtering more than 500 Arabs who took refuge in caves in the Dabra. By 1850 he had attained the rank of General of Division. On the outbreak of the Crimean war in 1855 he was given the command of the first corps, and soon succeeded Marshal Canrobert in the chief command before Sebastopol. On 8th September he stormed the Malakoff, the key of Sebastopol, for which exploit he was rewarded with a marshal's baton, and on his return to France was created Duc de Malakoff and a senator, and received a grant of 100,000 francs. In 1858 he came to London as the French ambassador, but resigned his post in the following year, and was named governor of Algeria, where he died on 22d May 1864. See Sir E. Hanley, *The War in the Crimea* (1869).

**Pelite Structure**, in Geology, applied to rocks which have a texture like that of dried mud.

**Pella**, the ancient capital of Macedonia, and the birthplace of Philip II. And Alexander the Great, was situated in the midst of marshes, a few miles NW. of Thessalonica, which stood half-way between it and the head of what is now the Gulf of Saloniki. Its royal castle had wall-paintings by Zeuxis.

**Pellagra** (Ital. *pelle agrì*, 'rough skin'), a disease, unknown prior to the first half of the 18th century, which is common among the peasantry of Northern Italy, and occurs also among the working class in Corfu, Roumania, the Landes and Girond in France, and Oviedo and elsewhere in Spain. But the headquarters of the disease are in the northern and north central provinces of Italy; it is unknown to the south of Rome and in the islands. It is an error to describe pelagra as the result of poverty alone—to call it *il delirio della miseria*; it is clearly traceable to the use, as the staple diet, of damaged and unwholesome maize, gathered before it is ripe, and stored carelessly—often in cellars or pits—in its wet state. The disease makes its appearance in spring, in the form of a reddish-brown rash, which smarted painfully to the exposed sun and air, and then on the back and feet; towards autumn this disappears, leaving, however, hard, dry spots on the skin, and returning with increased determination in the

**Pelican** (*Pelecanus crispus*).

and plicature, ecclesiastical and heraldic, of the so-called pelican feeding its young with its own blood were by no means quite like a pelican, and noted that a like tale was told by the Egyptians of the vulture. The story, which was unknown to the classical writers, seems to have originated in Egypt; and the love of the vulture for its young was proverbial there (see *Academy*, 1884, p. 87). The Rufous-necked Pelican (*P. fusca*) abounds in the West Indies and in many parts of America. Other species are found in other parts of the world, and in some places the number of pelicans is prodigious, particularly in some of the most southern parts of the world. See also *Heraldry*, Vol. V. p. 694.

**Pelican-fish** (*Euphrarpex pelecanoides*), a remarkable deep-sea Teleostean fish, described by

Vaillant in 1822. The body is somewhat pelike, and is fringed on the dorsal and ventral middle line with spinous rays. It is the region of the jaws, however, which is most remarkable, the gape
following spring, and again in each successive year, till the skin becomes shrivelled and yellow, or black in certain spots, and the body is reduced to a mummified state. A burning feeling in the mouth and bowels is an accompanying symptom, and profuse diarrhoea, along with a rapid wasting, and dropsey, is a frequent cause of death. As the disease progresses, disorders relating to the nervous system gradually develop, and culminate in melancholy, imbecility, or mania; death often ensues from delirium, or the wretched patients drag out their life within the walls of an asylum. In România 1,2, and in Corfin 3-2 per 1000 of the population, have died from pellagra, and 3688 deaths from pellagra, or 2.04 per 1000 of the estimated population; but in 1881 the proportion was 4.8, and since then it has steadily decreased, in part owing to the number of hospitals built within late years for the special treatment of this disease. See the official report, La Pellagra in Italia (Rome, 1880).

Pelligrini, CARLO, caricaturist, was born at Capua in 1839, came to London in 1865, and from 1868 till his death on 22d January 1889 was the "Ape" of Vanity Fair, the delineator of its inimitable series of cartoons of celebrities. Especially good was his statute in red plaster of Mr Lowe standing on a match-box (1871).

Pell'ico, SILVIO, an Italian poet, celebrated for his long and cruel imprisonment by the Austrians, was born 24th June 1788, at Saluzzo, in Piedmont, and was educated in Pignerol, where his father, Onorato Pellico, a lyric poet, had a silk-factory. In his sixteenth year he accompanied his sister Rosina (on her marriage) to Lyons, where he remained until Foscolo's Sepolcri awakened in him a strong patriotic feeling and an irresistible desire to return to Italy. Coming, about 1810, to Milan, he was warmly received by Ugo Foscolo and Vincenzo Monti, and became French tutor in the military school. His tragedies of Laodamia and Frenesce da Rimini gained him an honourable name amongst Italian poets. He again translated Manfred of Byron, with whom he had become acquainted. He lived in great intimacy with the most eminent patriots and authors of liberal views, and took an active part in a periodical, Conciatitore, which after a time was suppressed on account of its liberal tone. In 1829 he was arrested on a charge of Carbonarian, and sent to the prison of Sta Margherita, and afterwards to the Piombi at Venice. After two years' imprisonment he was condemned to death, but had his sentence commuted to fifteen years' imprisonment, and was carried to the fortress of Spielberg near Brinn; he was, however, liberated in August 1830. During his imprisonment he had written two other dramas; and afterwards published an account of his sufferings during his ten years' imprisonment, under the title Le mie Prigioni (Paris, 1833), which has been translated into many languages, and has made his name familiar where it would not have been known on account of his poetry. Pellico's health was never quite restored. The Marchioness of Barolo received him into her house at Turin as her secretary. Pellico subsequently published numerous tragedies and other poems, and a little catechism on the duties of man. He died January 31, 1854. See the Life by Chiron (Italian, 1852), and that by Bourdon (Paris, 5th ed. 1885).

Pellitoric, or WALL-PELLITORIC (Parietaria), a genus of plants of the natural order Urticaceae, having both unsexual and hermaphrodite flowers on the same plant, the perianth of both kinds 4-fld. The Common Pellitory (P. officinalis), which grows on old walls and heaps of rubbish in Britain and many parts of Europe and Asia, is a perennial herb, with erect or prostrate stems, ovate leaves, and inconspicuous flowers. It sometimes attracts attention from the manner in which the pollen is conti- nually discharged in hot summer days by an elastic movement of the filaments. It is an old domestic remedy as a diuretic, emollient, and refrigerant, but only as a diuretic it is really serviceable, a property which depends on the nitre it contains.

Pellitory (Parietaria officinalis).
a third expedition was planned against Alexander of Phere, who, as usual, was threatening the Thessalian towns. The command was given to Pelopidas, and in the summer he marched into Thessaly, where he won the battle of Cynocephalae, but was himself killed while too eagerly pursuing the foe.

**Peloponnesus** (the isle of Pelopia), now called the Morea (q.v.), a peninsula which formed the southern part of ancient Greece, Helias Proper being situated to the northward of the isthmus on which stood the city of Corinth. See GREECE. The whole area is less than 9000 sq. m. Among its most important cities were Sparta and Argos. Sparta acquired after the Messenian war a decided supremacy over the other states, and disputed the supremacy with Athens in a war of almost thirty years' duration (451-404 B.C.)—the famous Peloponnesian war, of which the history has been written by Thucydides.

**Pelops**, in Greek Mythology, the grandson of Zeus, and the son of Tantalus, was slain by his father, and served up at an entertainment which he gave to the gods, in order to test their omniscience. They were not deceived, and would not touch the horrible food; but Demeter, absorbed with grief for the loss of her daughter, ate part of a shoulder without observing. The gods then commanded the members to be thrown into a cauldron, out of which Clotho brought the boy again alive, and the want of the shoulder was supplied by an ivory one. According to the legend most general in later times, Pelops was a Phrygian, who, being driven by Ilos from Sipylos, came with great treasures to the peninsula which derived from him the name of Peloponnesus. Having purchased some skins, he entered the temple of Pan at Delphi, and after the contest purchased the cauldron of the god with Pan's flames. Pelops then married Hippodamia, obtained his father's kingdom by conquering him in a chariot-race, and became the father of Atreus, Thyestes, and other sons. But in what appear to be the oldest traditions he is represented as a Greek, and not as a foreigner. He was said to have revived the Olympic games, and was particularly honoured at Olympia.

**Pel's Fish-owl** (Scotopelia peli), so named from having been first discovered by Mr Pel, the Dutch commandant at Elmina, is found in West Africa from Senegambia to Gaboon, and in the Zambezi region in South-east Africa. It measures about 19 inches in length; its wing is 18 inches long. Its colour above is a deep rufous-brown crossed with numerous irregular bars of black; the wing is similarly barred; the under surface of the body is light brown with heart-shaped bars of black; the bill is of a dark-blue lead colour, and the iris is dark brown. The birds from the Zambezi are a little larger than those from West Africa. The natives regard this owl as a fetish bird possessing the power of destroying whatever it looks on; and curiously enough its presence in more than one locality has been followed by an outbreak of disease among domestic animals. See the Ibis for 1859, p. 445.

**Pelletier Effect.** See Electricity, Vol. IV. p. 276.

**Peltry**, a general term applied to the trade in skins of wild animals, and to the skins themselves. It is understood to mean only skins undressed, except by drying, and eddy those which, when dressed, are called Fur. See FUR.

**Pelusium**, the Greek name of an ancient Egyptian city, situated at the north-eastern angle of the Delta, and important as the key of Egypt on the Asiatic side. The eastern mouth of the Nile derived from it the epithet Pelusiac. Its identity with Sin of the Old Testament and the Greek Sais is doubtful. The *Ostium Pelusiacum* was choked up with sand as long ago as the 1st century B.C., and the whole district is a wilderness of sand and marshes.

**Pelvis.** This term is used to indicate one of the chief divisions of the skeleton. It consists of the sacrum, coccyx, and the innominate or haunch bones. Each of the latter originally consisted of three parts—ilium, ischium, pubis—which have become fused together. By the articulation of the pubic bones in the middle line anteriorly the innominate bones form the anterior and lateral aspects of the pelvis. Wedged in between them posteriorly are the sacrum and coccyx. Various powerful ligaments give support to and maintain the pelvic bones in position. Notwithstanding the importance of this part of the skeleton, the ancient Greek physician had no word whereby to designate it, and both Greek and Roman associated the sacrum and coccyx with the vertebral column, and the innominate bones with the lower extremities.

The pelvis is divided into two parts by a plane which extends from the upper margin or promontory of the sacrum to the upper margin of the articulation between the two public bones—i.e. the symphysis pubis. On the inner surface of each innominate bone a line may be traced from the sacral promontory to the symphysis pubis. This is named the ilio-pelvic line, and it helps to complete the circumference of the plane which divides the pelvis into two parts. The space above this plane lies mostly between the expanded iliac bones. It belongs to the abdomen proper, and is named the false pelvis. The space below the level of the sacral promontory and ilio-pelvic lines is called the true pelvis, and certain descriptive terms are employed in connection with it. Thus the plane which separates it from the false pelvis is called the inlet or brim of the true pelvis. Its inferior circumference or outlet extends from the tip of the coccyx to the inferior border of the pubic symphysis, and from the one ischial tuberosity to the other. Between the ischial tuberosities in front and extending forwards to the symphysis there is the subpubic arch. The space between the inlet and the outlet is named the cavity of the true pelvis. The measurements of the true pelvis are made along certain definite lines which are applicable to the brim, the cavity, or the outlet. These are (1) the antero-posterior or conjugate diameter—i.e. from the mesial line in front to the mesial line behind; (2) the transverse or widest diameter; (3) the oblique diameters—right and left. These extend from the articulation between sacrum and ilium on one side to the farthest point on the opposite side of the mesial plane. In the erect attitude of the body the plane of the brim of the true pelvis forms.

![Fig. 1.—Adult Human Pelvis, in situ:](attachment:image)
an angle with the horizontal which varies from 60° to 65°. Thus the weight of the upper part of the body which is communicated to the sacrum is directed downwards and transmitted through the innominate bones to the heads of the femora, and so to the inferior extremities. In addition to the ligaments, muscles, blood-vessels, and nerves which constitute the soft parts of the pelvis there are certain special organs which are present in both sexes, and others which are peculiar to each sex.

Thus, of those common to both sexes, there are the urinary bladder and the rectum. The urinary bladder is placed behind the symphyseal pubis, and only rises out of the pelvis into the abdomen when considerably distended. The rectum—a name applied to that part of the alimentary canal which passes through the pelvis—is placed on the front of the sacrum and coecyx, a short distance below which it terminates in the anus. The lower end of the rectum is supported by two muscles—the levatores ani—which surround it so completely as to form a floor or diaphragm for the pelvis. In addition to these organs there are others which are characteristic of the sexes. In the male we have the retecula seminale and the prostate gland—the latter surrounding the outlet of the urinary bladder. In the female we have the uteri, ovaries, and their various appendages. The diverse functions of these organs have led to corresponding and marked differences in the size and form of the osseous pelves of the sexes. In the female the bones are more slender, and the muscular impressions less distinct. The true pelvis has a greater breadth and capacity, but its perpendicular depth is less. The inlet is more nearly circular; the ischial tuberosities are wider apart, and the subpubic arch is much wider. All of these differences indicate special modifications in connection with the necessities of child-bearing. Although the depth of the cavity of the true pelvis steadily increases from childhood to puberty, yet the characteristics of the sexes are discernible even at birth.

But not only does the pelvis display features which are characteristic of sex; it also presents characters which are peculiar to individual races of mankind. In this field of study a great amount of valuable work has been contributed by Sir William Turner of Edinburgh University, and embodied in the reports of the Challenger expedition. In determining these features peculiar to race numerous measurements have been made, mostly in relation to the cavity of the true pelvis, with its brim and inlet; but many of the external dimensions of the entire pelvis have also been noted, as well as the dimensions of individual bones. One of the most valuable of the external measurements is the comparison between the maximum height and breadth of the entire pelvis. A common result is obtained by the following formula:

\[
\text{height} \times \frac{100}{\text{breadth}},
\]

which establishes what is called a breadth-height index. Another index of great importance is the result of a comparison between the conjugate and transverse diameters at the brim of the pelvis. This is named the pelvis or brim index, and is obtained by the formula, \(\text{conj. diam.} \times 100\). The measurements are usually recorded in millimetres. As the result of numerous measurements Sir William Turner has devised a classification of pelvises based upon the relation of the conjugate and transverse diameters at the brim of the true pelvis—i.e. upon the brim index. Thus, those pelvises in which the conjugate diameter of the brim is either longer than the transverse or closely approaches it are named dolichopellic (pelvis, the Greek equivalent of the Latin pelvis, 'a basin'; and dolichos, 'long'), and in those the brim index is above 95. When the transverse diameter of the brim greatly exceeds the conjugate they are named platypellic (platys, 'while'), and the brim index is below 90. In those where the transverse diameter is not greatly in excess of the conjugate, i.e. where the brim index varies between 90 and 95, both inclusive, the term mesatipellic (mesaitatos, 'middlemost') is applied. Grouping the pelvises under these headings we find that such races as Australians, Bushmen, Hottentots, Kaffirs, Malays, Andaman Islanders, &c. are dolichopellic. Negroes, New Caledonians, &c. are mesatipellic. British, French, Germans, Europeans generally, natives of India, Chinese, American Indians, &c. are platypellic. These results are obtained from the examination of male pelvises, since, as we have already seen, the female pelvis is modified in its diameters in relation to the special requirements of sex.

If now we compare the human pelvis with that of the lower mammals, we shall find that the human pelvis is characterised by breadth and shallowness and the great capacity of the true pelvis. When, therefore, the conjugate diameter at the brim of the pelvis is longer than the transverse—i.e. when the pelvis is dolichopellic—an approach is made to the condition which prevails even to a greater extent among the lower animals, and it is 'a diminished or abnormal' disposition, as compared with platypellic pelvis of Europeans.

We have seen that in man the weight of the trunk is transmitted to the lower limbs through the pelvis, whereas in quadrupeds the downward pressure of the weight of the trunk is differently disposed. Doubtless, therefore, the attitude has great influence in controlling the expansion of the pelvis in the transverse diameter when the parts are young and plastic. It may therefore be owing to the habits and mode of life of the black races in their aboriginal state that their pelvis approach the lower type. Take, for example, the aboriginal Australian who sits on the ground embracing his knees with his arms, or any of the savages whose favourite attitude is 'squatting'—i.e. sitting down with the body bent forward and the buttocks resting on the heels; or again, when in pursuit of a game a stooping or crouching attitude is adopted. In all these positions the pressure upon the sacrum and pelvis is diminished, and there is a tendency to approximate the conditions to those of the anthropoid apes, while the white man on the other hand preserves the erect attitude whether standing, sitting, or walking.

Pemba, a coral island off the east coast of Africa, lies 50 miles N.E. of Zanzibar Island, has a length of 46 miles and a breadth of 43; area, 372 sq. m. There are numerous bays on the east coast; on one of them stands the chief town, Chaka. The inhabitants, 50,000 in number, rear cattle and trade in rice, cloves, and ebony, all products of the
Island. It is under the same administration as the rest of the Transvaal Protectorate.

Pembina: a city (pop. 1900, 929), capital of Pembina County, North Dakota, on the Red River of the North, at the month of the Pembina River. By rail it is 68 miles SW. of Winnipeg and 203 NW. of St Paul; and its position makes it worthy of notice, as on the north it marks the boundary line between Manitoba and the United States, while on the east only the Red River separates it from Minnesota.

Pembroke, the county town of Pembroke shire, on a navigable creek of Milford Haven, 9 miles W. of Tenby and 50 W. by N. of Cardiff. On the extremity of the peninsula on which this town is built stands Pembroke Castle, founded in 1094 by Arnulf de Montgomery, a very imposing ruin, with a Norman keep 75 feet high and 52 in diameter. Beneath is a huge natural cavern, 70 by 50 feet. The birthplace of Henry VII., this castle in 1483 was taken by Cromwell after six weeks' siege. Monkton Priory, with its rootless Decorated choir, is another interesting structure. The Pembroke district of boroughs, returning one member, comprises Pembroke, Milford, Tenby, Wiston, and also (since 1885) Haverfordwest, Fishguard, and Newgale. To form a great horned ram, which has given the title of earl to the House of Herbert (q.v.). At Pembroke Dock, or Pater, 21 miles north-west, is the naval dockyard and arsenal, established in 1314. It embraces an area of 70 acres, and since 1861 has been acquired at a cost of more than a quarter of a million. Pop. of Pembroke (1861) 15,071; (1881) 18,339; of Pembroke Dock (1861) 10,190; (1891) 10,481.

Pembroke shire, a maritime county of South Wales, the westernmost of the Principality. Measuring 30 by 25 miles, it has an area of 611 sq. m., or 391,181 acres, of which three-fourths is arable. The coast-line is much of it rugged and precipitous; and inland the surface is undulating, green hills alternating with fertile valleys, and containing a maximum altitude of 1754 feet in the Preseli range, which traverses the north of the county from east to west; and there are the Towy separating Pembroke shire from Cardigan, and the East and the West Cleidion. The rocks are largely Silurian; the soil varies much in quality; and coal, slate, lead, and iron have been worked. St David's Cathedral and half-a-dozen medieval castles make the county notable for its old inscriptions, neolithic implements, and Roman coins. At Haverfordwest and Tenby a colony of Flemings was established in 1107. They adopted the English tongue; and Pembroke shire, or 'Little England beyond Wales,' is now over more than half its area inhabited by an English-speaking population, although it is the remotest of all the Welsh counties. It was harried by Owen Glendower in 1406; and on 23rd February 1707 it witnessed the last French invasion, when 600 regulars and 800 gentry, with the Fishguard fleet, found it necessary to surrender unconditionally to some militia and yeomanry under Lord Cavendish. Pembroke returns one member. Pop. (1801) 50,280; (1841) 88,044; (1891) 91,824; (1911) 80,123. See Fenton's 'History of The County of Pembroke' (1814).

Penman: This was originally a North American Indian preparation only. It was introduced into the British navy victualling-yards in order to supply Arctic expeditions with an easily-preserved food, containing the largest amount of nutriment in the smallest space. As made by the Labradorians, a portion of the last remnant of vestiges dried in the sun, or wind, and then pounded into a paste and tightly pressed into cakes; sometimes a few fruits of Alnus alba varia are added to improve the flavour. It will keep for a very long time uninjured. That made for the arctic voyagers was chiefly of beef. In making pemmican it is necessary to remove the fat completely.

Pemphigus, or Pemphigus, belongs to that order of skin diseases which is characterised by an eruption of large vesicles, filled with serous fluid, and known as bullae. The disease occurs both in the acute and in the chronic form. In the acute case of acutepemphigus, bullae, or blisters, from the size of a pea to that of a chestnut, appear in succession (chiefly on the extremities), and having continued three or four days break, form a thin scab, and soon heal, unaccompanied with febrile or inflammatory symptoms. In England it is observed in cases of considerable constitutional disturbance, the bullae are larger, and the scabs heal with difficulty. The chronic form differs mainly from the acute by its prolonged continuance. The acute variety chiefly affects children, and has been ascribed to Cincinnati, errors of diet, &c.; while the chronic form chiefly attacks aged persons, and is probably due to debility and impaired nutrition. The acute form usually requires nothing but soothing medicines and diet, and mild local dressings, such as simple cerate, to protect the raw surfaces from exposure to the air. In severe cases of pemphigus bullae, with the judicious use of tonics (iron, bark, &c.), is most commonly successful. In obstinate cases arsenic is sometimes of use.

Pen, an instrument for writing with a fluid ink. When the Egyptians, Greeks, Romans, and some other ancient nations wrote upon papyrus or parchment they used a reed pen (Lat. calamus), and when in the Arab states the legend is covered with wax they wrote upon them with a pointed style of bronze, bone, or other material. Some of these ancient reed pens have been preserved. One, now at Naples, was found in a papyrus at Herculanum. Reed pens are still the only kind used by the natives of Persia and some neighbouring countries. A metal pen does not suit their mode of writing. These reed pens are pointed much in the same way as quills, and are made from the reeds or stems of Phragmites communis, which is also a good writing plant. Eremites and probably other species of this genus. The Chinese and Japanese write with a small brush or hair-pen. Quills are known to have been used for writing with as early as the 7th century of our era, but long after that reed pens also were employed in Europe for official purposes.

Metal pens were in use, but probably only to a very limited extent, among the ancient Romans. In the museum at Naples there is a bronze pen, milled like a modern steel pen, which was found at Pompeii. Another of a somewhat different shape was discovered at Herculanum. Bronze and silver writing pens appear to have been occasionally made in the middle ages, but there is little doubt these were more curiosities than articles in general use, and the same may be said of all metallic pens of a recent date, sometimes referred to in books, until we come to the beginning of the 19th century. For centuries before that quills were universally employed among western nations, and in schools steel pens were only very partially substituted for them till about 1840. Perhaps the most metallic pens of which we have any certain knowledge were some made in 1780 by Mr Harrison, split-ring maker, Birmingham, for Dr Priestley. They were of sheet-steel, formed into a tube and filed into shape, the joining of the metal making the slit. Brass pens were afterwards made in England before the end of last century; one of these seems to have been in the Strawberry Hill collection of art objects and
curiosities (Walpole's), which was sold in London in 1842. In the early part of the century various plans were tried to produce pens more lasting than ordinary quills. The quills were pointed with metal, but the new cutting sodal acid and paraffin shell had small pieces of diamond and other hard gems embedded in them by pressure. Another plan was to attach gold to their points. Such pens were of course too costly for general use. Barred pens of steel made by Mr Wise were on sale in London in 1808 but the carbonizing soda was so expensive that they did not take the market. The first English patent for the manufacture of steel pens is that of Bryan Donkin in 1803. A patent, the first of its kind in America, was granted in 1810 to Peregrie William-son of Baltimore for the manufacture of metallic pens. Steel pens of the barrel type were being made in 1815 by Sheldon of Sedgley, the price being 18s. per dozen. By 1820 the number of manufacturers had increased. To Mr James Perry belongs the credit of bringing steel pens into general use. He began pen-making at Manchester in 1819, using the best Sheffield steel (from Swedish charcoal iron) for the purpose. Perry removed to Red Lion Square, London, and had developed the pen trade with remarkable energy before the prominent Birmingham makers, Mitchell, Gillott, and Mason, ever came into existence. He originated the method of making pens. He took out a patent for a new method of making pens in 1830, from hard, thin, elastic metal, and a 'length of slitted or cleft space' scarcely exceeding that of quill-pens; and he made other improvements in 1832. The greatest improve-ment in the manufacturing side of the subject was the screw handpress for the cutting out of pens, enabling the manufacturer to supply them cheaply and in quantities. At first the method of slitting pens by means of a press was kept a profound secret by Gillott and Mason. To Mr John Mitchell, Birmingham, has been assigned priority in this invention. Sir Josiah Mason made barrel pens in 1828, and 'slip' pens for Perry in 1829. At the end of 1875, when Sir Josiah Mason retired from his business, his output exceeded 32,000 gross weekly. The output in 1866 had increased to 50,000 gross weekly; and about 4000 people were employed in all departments. In 1886 the weekly average of pens manufactured was about 160,000 gross, or twenty-two million pens. There were four pen-works in the United States at the same date, only one of which was of terrestrial origin, and one in Germany. The most successful recent patents in connection with pens have been those dealing with points which are turned up or turned down, thickened or 'plumished,' for smooth writing. A leading pen-maker has a catalogue containing 5000 varieties of pens, while it has been estimated that no fewer than 100,000 different shapes and sizes are in the market. All the pen-makers now make pen-holders, and Josiah Mason has related that he made the first stick pen-holders for Perry in 1832, and Gillott in 1835. Pens are also made of silver, platinum, and alumin-ium bronze. They have also been made of vulcanite. The gold pen, which is incorrodible with ink, was also made in Birmingham for Mordan and others. Made in the United States as early as 1835, it has been also manufactured in Russia and Japan. One American firm manufactures 100,000 every year. The gold pen goes through more than forty-five different processes, from the gold-bar, purchased from the United States Assay Office, which is said to be employed, to the pen nib, and the nib to the point. To give firmness to the point of the pen it is pointed with iridium. The United States imports over half a million gross of steel pens annually, and manufactures one and a half million gross, at Cam-den, Meriden, and Philadelphia. The steel used is
mostly imported from Birmingham. In the style-
graph, or fountain pen, the nib is dispensed with, a
finely-tapered point connecting with the barrel
containing the ink; the first fountain pen was
brought out in 1848. See Bunce's Josiah Mason
(1800), which contains a sketch of the history of
the steel-pen trade.

Penance. See Catholic Emancipation, Ireland.

Penance Law. See Catholic Emancipation, Ireland.

Penance (Lat. penitentia), in Roman Catholic
theology, means both the sorrow for sin and also
the sacrament by which absolution is conveyed.
It means the voluntary or accepted self-inflicted
punishment by which a repentant sinner manifests
its sorrow for sin, and to avow the punishment which, even after the
guilt has been remitted, may still remain due to
the offence. Penance is believed in the Roman
Catholic Church to be one of the sacraments of the
Church, although it is not necessary to explain it
briefly both under its relations as a sacrament and
as a private personal exercise.

Penance as a state of mind is simply sorrow for
evil-doing, accompanied with a purpose of amend-
ment. Penance is the fruit or the manifestation of
its cause, which is a contrition or repentance,
or expressed by some of those external acts which
are the natural manifestations of any deep sorrow,
either negative, as the neglect of ordinary attention
to dress, to the care of the person, to the use of food,
or positive, as the direct acts of personal mortifica-
tion and self-inflicted pain, such as fasting, wearing
barelloth, stretching the head with ashes, watch-
ing of nights, sleeping on hard boards, &c. Such
manifestations of sorrow, whether from motives
of religion or from merely natural causes, are common
among the Eastern races, and are frequently alluded
to in the Scripture. Although, the form and manner
of the early Christians' penance found a prominent
place, and the chief acknowledged object of
the stated Fast (q.v.), and other works of mortifi-
cation which prevailed, was that of penitential
correction, or of the manifestation of sorrow for
sin.

A still more striking use of penance, however,
in the early church, was the disciplinary one; and
this, in the Roman Catholic view, is connected
with the sacramental character of penance. Any
discussion of this purely theological question would
be out of place here, and it will be enough to state
briefly that Roman Catholics number penance among
the Seven Sacraments, and believe it to be of direct divine institution (Matt. xviii. 18;
John xx. 23; 1 Cor. v. 5). The matter of this sacra-
ment consists, in their view, of the three acts of
the penitent—contrition, or heartfelt sorrow for
sin, as being an offence against God; confession,
or detailed accusation of one's self to a priest
approved for the purpose; and satisfaction, or the
acceptance and accomplishment of certain peni-
tential works, in atonement of the sin confessed.
The form of the sacrament is the sentence of
absolution from sin pronounced by the priest who
has received the confession, and has been satis-
fied with the penitential disposition of the self accuse-
ing sinner. In all these points, of course, they
differ from Protestants. Even in the apostolic
times the practice prevailed of excluding persons
of scandalous life from the spiritual fellowship of the
Christian community (see Excommunica-
tion). At times, the attempt was made to fix the day
it may be stated as certain, from the authority of
Tertullian and other writers, that from a very
early time the persons so excluded were subjected
to certain penitential regulations. The class of
offenders so treated were those who had been
notoriously guilty of the grievous crimes of idol-
alty or apostasy, murder, adultery, and other
scandalous offences. The period of penitential
proliferation differed in different times and places,
but in the primitive church it was gradually
narrowed, to the enormity of the sin, some going so far in their
rigour (see Novation) as, contrary to the clearly-
expressed sense of the church, to carry it even
beyond the grave. In the earlier ages much depended upon the spirit of each particular
church and its laws. About the 4th century the public
penitential discipline assumed a settled form,
which, especially as established in the Greek
Church, is so curious that it deserves to be briefly
described. Sinners of the clergy, already referred
to had their names enrolled, and were (in some
churches, after having made a preliminary con-
ession to a priest appointed for the purpose)
admitted, with a blessing and other ceremonial,
by the bishop to the rank of penitents. This
enrolment appears to have commonly taken place
on the appointed day of indulgence, which were
errolled arranged in four grades, called—1. (Gr. prosklainotes, Lat. fluente) 'WEEPERS'; 2.
(Gr. akroámenoi, Lat. audientes) 'HEARERS'; 3. (Gr.
hypoppontes, Lat. prosternentes) 'PRAYERSTERS';
4. (Gr. s franticas, Lat. consistentes) 'STANDERS.' Of
these classes the first two hardly appear in the
Western Church. It is a subject of contro-
versy whether, and how far, this discipline was
extended to other than public sinners; but it seems
certain that individuals, not publically known as
sinners, voluntarily enrolled themselves among
the penitents. All four grades were a distinguishing
penitential dress, in which they appeared on all
occasions of public worship, and were obliged to
observe certain rules of life, to renounce certain
indulgences and luxuries, and to practise certain
austerities. In some churches they were employed
in the service of the sick, the poor, and others of
the more laborious works of charity. The
penitent, in ordinary cases, could only be restored
to communion by the bishop who had excluded him,
and this only at the expiration of the appointed
time, unless his life might be shortened; but in
case of dangerous illness he might be readmitted,
with the condition, however, that if he recovered
from the illness the whole course of penance
should be completed. The reconciliation of peni-
tents took place commonly in Holy Week, and
was publicly performed by the bishop in the
church, with prayer and imposition of hands. In
was followed by the administration of communion. If any of the clergy were guilty of a crime to
which public penance was annexed, they were first
deposed from the rank of the clergy, and then
subjected to the ordeal, like the laity themselves.
This public discipline continued in force with
greater or less exactness in the 5th, 6th, and 7th
centuries, and was followed by semi-public,
and ultimately by private penance. In the 11th and 12th centuries the public penance
had entirely disappeared. The nature and origin of
private penance is a subject of controversy
between Catholics and Protestants; the former
calling it an ancient practice of the Church,
and the latter that it held the same place even in the ages of
public penance for secret sins which the public
penance did for public offences. At all events,
from the date of the cessation of the public dis-
cipline it has existed universally in the Roman
Church. The priest, in absolving the penitent,
imposes upon him the obligation of reciting certain
prayers, undergoing certain works of mortification,
or performing certain devotional exercises. These
acts of the penitent are held to form an integral
part of his criminal proceedings; in which he is
responsible for the same as if he were a
person.
An approach to the Roman
Catholic polity on the subject was in use among
the English Puritans of the 17th century, and more
particularly in the Church of Scotland during that
and the succeeding century, when it was common
'to make public penance on the Stool of
Repentance' (q.v.). In Ayrshire the kirk-sessions
were accustomed regularly to provide sackcloth
suit for ecclesiastical offenders as late as 1781; a
heinous breach of the seventh commandment might involve
the infliction of public penance, which, however,
(1844), desiring him to procure a 'discipline' and 'send it by R.' What was described to me was of
a very sacred character: five cords each with five
knots, in memory of the five wounds of our
Lord. I should be glad to know also whether there
were zealous adherents of their doctrinal
opinions that in all this they adopted practices
incongruous with their creed, and in harmony rather
with that of the Church of Rome. Nor do they seem
to have perceived that Church Discipline (q.v., in
its proper sense, as distinguished from ecclesiastical
rights and privileges, is wholly distinct from the imposition
of penalties by churches or church courts.
Penitential humiliations, imposed by ecclesiastical
authority, are now no more in favour where church
discipline is most strict than where the utmost laxity
prevails. The commutation of penalties is
deemed shameful, for a fine to the poor of
the parish, was an abuse once prevalent in Scotland,
but never sanctioned by the higher ecclesiastical
authorities.

PENANG

(Penang, 'Betei-nut Island'), the official but less used name of which is PRINCE
OF WALES ISLAND, one of the British Straits
Settlements, q.v., lies at the northern extremity of
the Strait of Malacca, 2 to 10 miles from the
west coast of the Malay Peninsula, and 360 miles
N.N.W. of Singapore. Length, 15 miles; breadth,
5 to 10 miles; area, 107 sq. m., three-fifths being
hilly. A sanatorium crowns the highest point,
2920 feet above sea-level. The whole is covered
with forest trees, and is without a large area of
tropical palms predominating. In the low lands the
thermometer ranges from 70° to 95°, and at the sanar-
torium from 60° to 75°. The rainfall averages
111 inches a year. Penang is a great shipping
centre for the products of the native states of the
Malayan Peninsula. The principal town of Penang
has greatly increased of late years. In 1888 the imports and exports combined reached a
total value of £15,423,458; in 1896-98 the annual
value of imports alone exceeded £10,000,000, and
of exports only a little less. By far the most im-
portant export is tin; the next being spices, sugar,
and tobacco. Georgetown, the capital, is situated
at the north-east extremity of the island, and is
defended by forts; pop. about 25,000. Province
Wellesley, on the peninsula opposite, forms part
of this same settlement. The government of Penang,
including Province Wellesley and the Dindings,
(1881) 190,597; (1891) 235,618, one-half
Chinese, nearly one-fourth Malays, and one-sixth
Tamils and others from India. Nearly two-thirds
of the total are males. Many thousands of Chinese
and Indians settling on Penang, and the arrivals
(120,896 Chinese and 20,599 Indians in 1887) are
not balanced by the departures. Province Wel-
lesley, 45 miles in length by 4 to 11 in breadth,
with an area of 276 sq. m., produces tapioca, sugar,
rice, and cocoa-nuts. Another dependency of the
settlement is the island of Penang, including the
island of Tawar, situated about 8 miles S. of Penang.
Pop. 2392. The native raja of Kedah ceded Penang
to the English in 1785 in return for an annual
pension of £1000. Thirteen years later the same
power acquired what is now Province Wellesley,
for the purpose of putting down piracy. In 1805
the East India Company, the proprietors of the
settlement, made Penang a presidency of equal
rank with Bombay and Madras. From 1826
Singapore and Malacca were united with it, but
in 1821 the government of the settlement was transferred from Penang to Singapore.

PENANG LAWYERS is the commercial name for
the stems of a species of palm imported from
Penang for walking-sticks. They are small and
hard, and have a portion of the root-stock attached, which is left to form the handle.

Pemquat Beds. See THASSIC SYSTEM.

Penates. See LARIS.

Pencils.

Pencils. A slender stick of black lead, slate, or coloured chalk, encased in a small round
piece of wood, is called a pencil; but the term is
also applied to small hair-brushes used by artists,
and it was to these that the name was originally
given. Some early manuscripts have lines upon
them ruled with ordinary metallic lead. When
pencils of Black Lead (q.v.), called also graphite and
plumbago, were first used it was uncertain, but
Beckmann points out that they are distinctly
mentioned in a book on fossils by Conrad Gesner,
printed at Zurich in 1553. The discovery of the
use of black lead as a material for writing or
drawing with was made accidentally; in some forms
where words or lines may require to be frequently
rubbed out no other substance has such valuable
properties.

For a long time the plumago from the Borrow-
lake mines in Cumberland furnished the "true"
for the best pencils ever made. These mines
have been exhausted since 1850; but when the
PENCILS

graphite from there was available it had, in the case of the larger and purer pieces, only to be cut into square rods of the proper size for pencils. In order to work up the smaller bits, cuttings, and dust of this precious material, Mr W. Brockedon, in 1843, patented a method by which he first reduced the cuttings to a very fine powder, then pressed these small pieces to powder, and then, by subjecting it to great pressure in dies from which air is exhausted, produced a cake as solid and compact as the natural graphite, and equally suitable for cutting into leads. For a considerable number of years past, owing to the Borrowstounness patents, powdery pencils, as well as colour pencils or crayons, have been made by the process invented about the close of the 18th century by Conté of Paris, which consists in thoroughly mixing the black lead with clay, both being first reduced to a state of fine division and most carefully purified. The proportions of graphite and clay vary from two of the latter to one of the former (for light hard pencils) to equal parts of the two ingredients (for the dark soft kinds). Water is added to the mixture, which is repeatedly ground, and then placed in conical moulds and squeezed in a mangle press till it acquires the consistency of stiff dough. In this state it is placed in a strong metal cylinder, whose bottom is perforated with apertures of the proper size for the section of the pencil leads. The black-lead mixture, being heated, is made into thin sheets cut through the apertures by a plunger into continuous strips or threads, which are arranged in straight lengths on a board to dry. After being exposed to a slight artificial heat, the strips are cut into the usual lengths for pencils, and placed in a covered crucible, which is raised to a red heat. When cooled they are ready for use.

An extensive mine of fine graphite was opened at Bogdalsk in eastern Siberia about 1850. Much of this black lead is scarcely if at all inferior in quality to that formerly obtained in Cumberland. Pencils have been made from this graphite in the unmixed state, and Faber of Nuremberg still makes fine pencils of it. These have the words 'Graphite de Sibérie' stamped upon them. Dixon's American graphite pencils are made from the famous "Inchamud" mine at Ticonderoga on Lake George, but it is mixed with clay as above described. Workable deposits of graphite are found at several places in Canada. A good deal of what occurs in the township of Buckingham, in the province of Quebec, is almost pure, and is made into pencils. For other localities, see BLACK LEAD.

The wood used for pencils is invariably that of the Virginia or Florida cedar (see JUNIPER), which, being straight grained and easily cut, is remarkably well suited for the purpose. Two rectangular pieces of the proper size, cut out by machinery, go to make a pencil, the one containing the groove for the lead being thicker than the other. After the lead is inserted the two pieces are glued together, and then cut to a round shape by revolving cutters. The operations of cutting out the square fillets of wood and rounding them after they are glued are very rapidly performed. Pencils are sometimes cut in a hexagonal shape. Besides the maker's name, letters indicating the character of the lead are stamped on the pencils. For Great Britain these are II, III, IV, IVH, IVH, HIH, IIIH, IIIH, and F. II signifies hard; once and twice repeated it means harder and very hard. B stands for black (and soft), and, when repeated, for still blacker. The softer grades generally are more useful, and are in the series: soft, HB, H, F. In the United States the letters used differ somewhat. They are II, hard; VII, very hard; VVII, still harder; H, soft; VI, very soft; VVI, still softer, for deep black shading; M, medium; MI, medium hard; MB, medium black.

Owing to the multiplicity of processes for reproducing pen-and-ink drawings (see ILLUSTRATION), and the cultivation of that method for book illustration, the black-lead pencil is much less used now than in the earlier half of the 19th century. Drawings in chalk or charcoal, since either material makes a much blacker line, have usually deeper and more effective shading than can be given with pencil. Still, a finished drawing in black lead by a skilled hand has charms of its own, and it is to be regretted that so few of these of any importance are now made by artists of high standing.

Coloured pencils are made with ordinary pigments—e.g. Prussian blue and chrome yellow for their respective colours—mixed with white wax and tallow or with gum and tallow, clay being sometimes added; but none of these coloured preparations are heated like those made of graphite and clay.

The arrangement of a small rod of black lead, which is kept projecting as it wears away from a tube fitted to a metal pencil-case, and which has since been so much used, was patented by Hawkins now in the familiar alloy of lead, antimony, and a little mercury is made into ever-pointed pencils for writing on paper prepared with a suitable surface.

The manufacture of black-lead and coloured pencils is carried on extensively at Nuremberg, where there are more than a score of factories, employing in all nearly 6000 hands, and producing annually some 250 million pencils, worth about £420,000. Faber founded a branch in New York in 1861. Four years later the Eagle and American Pencil Companies were established, and the other such firms, the Dixon Crucible Company, in 1872.

**Pendant.** A hanging ornament, used in ceilings, vaults, staircases, timber-foots, &c. It is sometimes a simple ball and sometimes elaborately ornamented, and is chiefly used in the later Gothic and Elizabethan styles.

**Pendulum.** See **FLAG.**

**Pendennis Castle.** See **FALMOUTH.**

**Pendle Hill.** See **CLITHEROE.**

**Pendleton,** a north-western suburb of Manchester, wholly within the borough of Salford. Pop. 40,240.

**Pendragon.** See **DRAGON.**

**Pendulum.** The two chief varieties are the simple pendulum and the ordinary or compound pendulum. Examples of the latter occur in all the former clocks, where a balance-wheel has been dispensed with (see **HORLOGE**), a small leaden or golden bullet, when suspended from a fixed point by an extremely fine thread, may represent a simple pendulum, provided it vibrates in a small circular arc. Once set in motion, this instrument will move in the same arc for ever unless interfered with, because at each swing, when descending through the first half of
its circular path, it acquires energy enough to raise it to an equal height on the opposite side. In ordinary experiments the bullet will perform many thousand revolutions, and, by itself, before the resistance of the air and other interferences cause the movement to subside and at last cease, by imperceptibly diminishing the length of the arc.

This long-continued and self-sustaining action is manifestly due to the attraction of the earth, the forces that cause it to fall to the ground, because at the end of each swing of the bullet its weight tends to pull it vertically downwards, and the string constrains it to repeat its course along the circular arc. A most interesting and valuable application of the pendulum, therefore, is for measuring the acceleration of velocities of falling bodies. For that purpose it is much superior to Atwood’s Machine (q.v.) or any other method which has yet been devised.

If the circular path or swing is short—not exceeding, for example, that of a clock pendulum which beats seconds—there are two results to be remembered. First, that so long as the length of thread is unchanged, it matters not how far the bullet may swing on each side, the time or duration of each oscillation is also unchanged. This is the principle upon which the pendulum is fixed in the church of Pisa, as he watched a lamp swinging by a chain. The quality that each swing occupies the same time is so important in horology that the introduction of the pendulum by Huygens as a time-measurer formed the principal epoch in the history of clocks. It means too, that a clock is isochronous (‘equal-timeliness’) was invented to mark this property of the pendulum. The second law of the pendulum is that to make the bullet move faster we must shorten the thread in the following proportion; for every time we double the length of the thread, we must take one-sixteenth the length. That law is otherwise expressed by saying the length of the thread is inversely as the square of the number of oscillations made in a given time (see CENTRE OF OSCIL-

These and other properties of the pendulum are wrapped up in the formula: \( \omega = \sqrt{\frac{g}{l}} \), which mathematicians have established: where \( \omega \) is time in seconds of one oscillation, \( l \) is length (in inches) of pendulum, \( g \) is the gravitational force of gravity, and \( g \) is the accelerating force of gravity, or twice the space through which a heavy body falls in one second. When \( t = 1 \) in that formula —i.e., when our pendulum beats seconds, a result easily attained at any part of the world—then immediately we have \( g = \pi^2 = 9.8696 \). In other words, multiply the length of the seconds pendulum in any latitude or longitude by the fixed number 9.8696 to find the value of \( g \). By this valuable and simple result it has been shown that the force of gravity slightly and gradually increases as we travel from the equator towards either pole, the length of the seconds pendulum diminishing in the same proportion. The poles are therefore nearer to the centre than the equator is, which is an independent proof that our planet is not a sphere but rather an ellipsoid in shape an orange rather than a lemon.

The following table readily gives the length of the seconds pendulum at any of the stations by dividing the corresponding number in the third column by 39.36. The length of the seconds pendulum, for example, is 32.191 \( \div 9.8696 = 3.262 \) feet, length of seconds pendulum. Dent’s clock in the tower of the House of Commons beats once in two seconds, and must therefore have a pendulum 13.046 feet long.

The table also shows the acceleration (feet per second) due to gravity, as ascertained from observations made by means of the seconds pendulum. The results are arranged in the order of their latitude, as shown by itself, before the resistance of the air and other interferences cause the movement to subside and at last cease, by imperceptibly diminishing the length of the arc.

Since the length of the seconds pendulum is due entirely to natural causes, and can always be easily verified, it was chosen as a standard of the British measures of length. Experience has taught, however, that these are much more easily known by preserving an artificial standard.

The universal application of the pendulum for time-measurement and ascertaining the local value of \( g \) has been followed by some special uses of it which are of interest. Thus, Sir G. B. Airy, the late astronomer-royal, has applied it to find the density of the earth’s mean density by observations taken at a coal-pit, 1200 feet deep, near South Shields. One pendulum being stationed at the surface and another at the bottom of the pit, their oscillations were measured and by means of an electric wire, with the result that if a clock were at the mouth of the pit it would gain 24 seconds per day if removed to the bottom. From these data (Phil. Trans. 1856, p. 297) the density of the earth was estimated to be 5.965.

By the Foucault experiment the pendulum was utilised in a striking manner to prove the perpetual rotation of our planet round its axis. A globe of metal is suspended by a long wire to a lofty roof, the point of suspension being vertically over the centre of a round table; and after being drawn aside from the position of rest this pendulum is allowed to begin its vibrations, but so as to have no tendency to right or left. Students of dynamics know that it must continue swinging to and fro in the same plane unless interfered with from without. Owing to that the table beneath the pendulum, when carefully observed, would revolve very slowly in a direction contrary to the hands of a watch; but since the floor and whole building revolve with the table, the observers naturally refer the relative motion to the pendulum, still swinging in its original plane. By marking twenty-four equal divisions round the edge of the table the spectators would be furnished with a good clock, the pendulum pointing out the hour at the point where it first began its oscillations, and apparently revolving in the usual direction.

The pendulum, in Horology, is absolutely accurate as a time-keeper, if only the proper length is preserved. That is mainly done by means of a screw turning on the rod, under the bob or ball, so as to push it up and therefore shorten the pendulum, or let it fall lower down and lengthen the pendulum. It was found in winter that clocks went too fast, and at midsummer too slow, because cold shortened the metallic rod and heat lengthened it. A further refinement of royal chronometers was to secure a uniform length without the screw adjustment, the result being what are known as ‘compensation pendulums.’ Both the common methods of these depend on the same principle. (A simple and practically accurate form of pendulum is made with a wooden rod, which is less liable to expansion.
Penelope, in Homeric legend, the wife of Ulysses (Odysseus), and mother of Telemachus, who was still an infant when Ulysses went to the Trojan war. During his long wanderings after the fall of Troy he was generally regarded as dead, and Penelope was vexed by the urgent wooing of many suitors, whom she put off on the pretext that she must first weave a shroud for Laertes, her aged father-in-law. To protract the time she undid by night the portion of the web which she had woven by day. When the suitors had discovered this device her position became more difficult than before; but fortunately Ulysses returned in time to rescue his chaste spouse from their distasteful importunities. Later tradition represents Penelope in a very different light, asserting that by Hermes (Marscury), or by all her suitors together, she became the mother of Pan (q.v.), and that Ulysses, on his return, divorced her.

Penguin. This name is applied to a group of birds containing three genera, Spheniscus, Eudyptes, and Aptenodytes—the largest species, the "Empress" (A. forsteri, 50 inches in height) and "King" (A. penantii) penguins, belonging to the latter genus. The most remarkable peculiarity of these birds is the flattened wing, which is clad with flat scale-like feathers; the whole limb, unfit for flight, is admirably suited for swimming. The feathers of the penguin—instead of being disposed in feather-tracts, separated by intervals (apterous) upon which no feathers grow, as is the case with all other birds, not excepting even the ostrich and cassowary—form a continuous covering to the body. These peculiarities are combined with some others in internal structure, mark off the penguins as a very distinct group of birds. By some they are placed in the same group with the auks, or in a special group (Impens) by themselves. The penguins are entirely confined to the Antarctic and to the south temperate regions (Patagonia, Cape Colony, Australia, New Zealand), and are aquatic in their habits, as is shown by the webbed feet as well as by the remarkable modification of the wings, adapted to the water. In some situations they are extremely abundant, and make their nests in a common area; the nest is nothing more than a hole in the sand in which the female deposits a single egg. The stupidity of these birds is perhaps due to the inaccessibility of the rocks and shores where so great a number live and breed; having been comparatively little interfered with by man, they show no terror at the sight of him. When intruders invade their breeding-places they can and do, however, inflict severe wounds with their sharp bills. The plumage of the neck is valued by furriers for collars and tippets; and large numbers of "Johnnies," as the sailors call them, are slaughtered annually. The flesh though dark is wholesome food, and makes excellent "hare-soup;" the belly is loaded with fat. That the penguins are not altogether a modern race of birds is shown by the remains of a species—Aptenodytes antarcticus—which existed in New Zealand in late Eocene or early Miocene times. This bird differed from existing penguins in having rather longer wings, and may therefore conceivably have possessed the power of flight; it was a large form like the King Penguin of to-day.

Penicillaria. See GUINEA CORN, and MILLET.

Penicillin, a town of Edinburghshire, on the left bank of the North Esk, 10 miles S. of Edinburgh by road, but by a branch line (1572). It has a Romanesque church-tower and large paper-mills, dating from 1709; whilst 2 miles NNE. are Glencorse barracks (1804–82), originally a dépôt for French prisoners. Pop. (1841) 907; (1891) 3362. See Wilson's Annals of Penicillin (Edin. 1891).

Peninsular and Oriental Company carry mails and passengers between Great Britain and India, China, and Australia. The company in its present form was incorporated by royal charter in 1840, although it had then had an existence of three years' duration as the Peninsular Company, which carried mails to Portugal and the south of Spain, and afterwards to Egypt. The "P. & O." own a fleet of about sixty vessels, of an average size of 5000 tons each. They carry mails from Brindisi to Bombay, weekly, in the contracted time of 12½ days; from Brindisi to Shanghai, fortnightly, in 31 days; and from Brindisi to Adelaide, fortnightly, in 24½ days. The company also maintains a three-weekly service between Venice, Brindisi, and Egypt, and in Asia has lines from Bombay to Colombo, thence to Calcutta, and to Singapore, Hong-kong, Shanghai, and Japanese ports. See the company's Pocket-book and Monthly Handbook; and for information on other great shipping lines, see the article SHIPBUILDING in this work, and works there cited.

King Penguin (Aptenodytes penantii).
Peninsular War (1807-14). The dissensions between Charles IV., king of Spain, and his son Ferdinand gave the Emperor Napoleon I. an opportunity of interfering in the affairs of that country. In pursuance of a treaty ratified on 29th October 1807, with the Spanish king, he had sent an army into Portugal under Junot, by whom Lisbon was seized, and the members of the royal house of Braganza obliged to flee to the Brazils. Ostensibly with the object of suppressing Junot's army, other French troops gradually occupied Salamanca, Valladolid, and other important positions in Spain, including Madrid, where Murat was in command. A popular outbreak against the king and his favourite, Manuel Godoy, caused the former to abdicate and his son Ferdinand to assume the crown. But the latter was induced to meet the French emperor at Bayonne, and by him held a prisoner, while his father was again proclaimed King. Riots at Madrid, Toledo, and other places during the spring of 1808 caused several deaths, and alarm that he surrendered his crown to Napoleon, by whom it was bestowed upon his brother Joseph Bonaparte, then king of Naples. He was proclaimed in Madrid on 24th July 1808.

Owing to the large powers of the local juntas, and the successful resistance fleets, the action of the capital of Spain had little effect upon that of her provinces, which rose against the French and those who favoured them in all directions. The organised forces of Spain amounted at this time to about 127,000 of all arms, while the French of the Peninsular army, consisting of 78,000 men, and of various nations, French, Swiss, Italians, and even Portuguese, was reinforced by 20,000 fresh troops. The French troops, clothing, and money were supplied by Britain to the patriots of Spain and Portugal, whose numbers rapidly increased. The first operations of the French under Marshal Bessières in the north were uniformly successful, except at Saragossa, which Wellington gallantly held against Lefebvre-Dessoumes. In Catalonia they suffered several defeats, and in Andalusia their general, Dupont, surrendered at Baylen with 18,000 men. The first armed interference of the British in the affairs of the Peninsula was the despatch on 12th July 1808 of Sir Arthur Wellesley with some 30,000 men to Lisbon, where the Tagus was fordable. Wellington, with Junot at Torla, and Soult in the meantime had defeated the Spanish at Almoradi, and captured the fortress of Badajoz. He also invested Cadiz, but General Graham with a force of 12,000 men attacked and defeated Marshal Victor's covering force at Barros on 5th March, which checked his further movements. Wellington, now designating to march on Madrid and thence against the French line of communications with Bayonne, found it necessary to capture Badajoz and Almeida. Massena, at the head of 50,000 men, marched to the relief of the latter place. He was checked at Fuentes de Oñoro on 5th May, where a hard-fought battle caused him to retreat and abandon Almeida to the British. Wellington then turned towards Badajoz, which Soult endeavoured to relieve with a force of 23,000 men. The British (7000) and Spaniards (25,000) engaged him on the 16th May in the bloody battle of Albuera, compelling him to retire, which he did in a southerly direction.

Matters were, however, in a very critical state for the British in the valley of Valencia, Asturias, and Galicia was in the hands of the French, who still had nearly 300,000 men in Spain, and had received no other check except from General Hill in Extremadura and at Tarifa, which fortress repelled Soult. Napoleon, too, threatened to take the field again in person. But this was prevented

Sent out, found matters on 22d April 1809. The French armies in Spain now numbered nearly 400,000 men, divided into eight corps d'armée, under six marshals, and operating in the north, south, east, and west. So long as Napoleon himself was able to direct operations they were characterised by unity of purpose and consequent success. Saragossa, attacked for the third time, after a memorable defence of sixty-three days, surrendered to Marshal Soult on 21st February 1809, and many victories were gained over the Spanish levies; but in Catalonia St. Cyrr effected comparatively little. The outbreak of war in Germany drew Napoleon to that country in April, and the operations in Spain were somewhat neglected in consequence. The jealousies of the French commanders too prevented any unity of action there.

Sir A. Wellesley first marched against Soult with 20,000 British and 40,000 Spanish under Cuesta, and drove him out of Portugal, to avoid Joseph, with 80,000 men under Marshal Victor, attacked at Talavera on 26th July and suffered a severe defeat. For this victory Sir A. Wellesley was created Viscount Wellington, but, being left without reinforcements, he was obliged to retire to Almeida. Wellington drove Junot out of Seville (November 20) enabled the French to overrun the whole of Andalusia, except Cadiz, which still held out. Wellington, foreseeing the impossibility of taking the offensive at that time, prepared during the winter a triple line of earthworks, 29 miles long, from Torres Vedras on the Zizarrara to Alhambra on the Tagus, thus covering his base at Lisbon. The French, 65,000 strong, under Massena, moved against him in the spring of 1810, captured the fortress of Ciudad Rodrigo on the 11th July, and attacked Béjar on 13th September. The attack was beaten off, and Wellington, carrying out his pre-conceived plan, retired slowly into the lines of Torres Vedras, carrying with him as much of the resources of the country as possible, and directing the Portuguese troops to harass the flanks and rear of the French. To avoid starvation Massena, finding himself unable to attack Wellington's fortifications, and having lost 30,000 men, began to retire on 14th November. Reinforcements having reached Wellington early in 1811, he followed, defeated Massena at Sabugal on 26th April, and forced him to the junction of the Douro and the Tagus, but Soult in the meantime had defeated the Spaniards at Gómez (February 19), and captured the fortress of Badajoz. He also invested Cadiz, but General Graham with a force of 12,000 men attacked and defeated Marshal Victor's covering force at Barros on 5th March, which checked his further movements. Wellington, now designating to march on Madrid and thence against the French line of communications with Bayonne, found it necessary to capture Badajoz and Almeida. Massena, at the head of 50,000 men, marched to the relief of the latter place. He was checked at Fuentes de Oñoro on 5th May, where a hard-fought battle caused him to retreat and abandon Almeida to the British. Wellington then turned towards Badajoz, which Soult endeavoured to relieve with a force of 23,000 men. The British (7000) and Spaniards (25,000) engaged him on the 16th May in the bloody battle of Albuera, compelling him to retire, which he did in a southerly direction.

Matters were, however, in a very critical state for the British in the valley of Valencia, Asturias, and Galicia was in the hands of the French, who still had nearly 300,000 men in Spain, and had received no other check except from General Hill in Extremadura and at Tarifa, which fortress repelled Soult. Napoleon, too, threatened to take the field again in person. But this was prevented
by the outbreak of war between France and Russia, and early in 1812 Wellington commenced his well-
known plan of investing Spain's French invader. He captured Ciudad Rodrigo on 19th January, 
stormed Badajoz on 6th April, and called in Hill's 
division from the south. Marmont, who had col-
lected his troops about Salamanca, found his flank 
threatened, and had at first to retire; but on 22d 
July the British lines of communications, and Clausew, 
who succeeded Marmont, proved so formidable a 
general that Wellington again found himself obliged 
to retire towards Salamanca and Portugal.

Events elsewhere, however, lessened the power of his 
enemy, and reducing the troops at Badajoz, 
Joseph was sent to Paris. Wellington's position was strengthened by his 
appointment as commander-in-chief of the Spanish 
and Portuguese armies. These now amounted to 
200,000 men, of which 70,000 Anglo-Portuguese 
had been brought over from England. 
He again advanced eastward in the spring of 1813, 
obliging the French to evacuate Hurgos and 
the line of the Ebro. They attempted to withstand 
him at Vittoria on 21st June, but sustained a 
crushing defeat, abandoning all their artillery, 
to, and baggage. The blockades of Pamplona 
and St Sebastian followed. Joseph, who had 
quarrelled with Soult, was superseded in 
the command, which was given to the latter. 
In spite, however, of great skill on his part, a series 
of terrible disasters had in the Pyrenees had uniformly 
disasters to him. St Sebastian was taken on 
7th October, the victory of Nivelle won on 10th 
November, and Wellington enabled to base 
himself on the northern ports. In February 1814 
Bayonne was invested, on 27th Soult was defeated 
at Orthez, and again at Toulouse on 10th April, 
which city was occupied by the British. But 
Marmont had already deserted, having, after the 
disasters Russian campaign, been overpowered by 
the allied forces of Russia, Prussia, and Austria, by 
whom France had to sign the Treaty of Paris taken. See 
also articles on France, Spain, 1812-13, Wellington, 
Napoleon, Soult, Massena, Sir John Moore, 
Vittoria, Badajoz, Teressa Vedra, Corum, Husceca, 
&c.; and Sir W. Napier's History of the Peninsular 
War (6 vols. 1829-40).

Penitential Psalms, seven of the Psalms of 
David, so called as being especially expressive of 
sorrow for sin, and accepted by Christian devotion as 
forms of prayer suitable for the repentant 
sinner. They are Psalms vi., xxxii., xxxvii., li., 
ci., cxxx., and cxliv. according to the Authorised 
Version, which correspond with vi., xxxvii., xxxviii., I., 
li., cxx., and cxlii. of the Vulgate. These 
Psalms have been selected apart from the others, 
period, and are referred to as such by Origen. 
Pope Innocent III. ordered that they should be 
recited in Lent. They have a special place in the 
Roman Breviary, and more than one of the popes 
attacked and punished to the recall of them. 
The most deeply penitential, and therefore more 
in use, both public and private, is the 51st Psalm, or 
the Misereere (50th in the Vulgate).

Penitentiary, the name given to one of the 
offices of the Papal court, and also to the dignitary 
(a cardinal, called Penitentiarius) who presided 
over it. The subjects which come under the 
notice of the Penitentiary, all those relating to the 
confessional, especially the absolution from 
sins and from canonical censures, reserved to the 
pope, and in certain cases dispensations from the 
impediments of marriage. See PRISONS.

Penkridge, a town of Staffordshire, on the 
Penn, 6 miles N. of Stafford by rail. In an 
aricultural 
district. Pop. 3134.

Penmaenmawr, a watering-place of Carnar-
vonshire, 4 miles S.W. of Conway by rail. The mountain of Penmaenmawr, the northern extremity 
of the Snowdon group, is 1553 feet high; on its 
summit are the remains of a great British fort, 
Dinas Penmaen.

Penn, Williams, the founder of the colony 
of Pennsylvania, was born at Reading, 1644. 
Penn, and was born at London, 14th October 1644. 
His early years were spent partly in Essex 
and partly in Ireland, where his father had several 
estates, the gift of Cromwell. Penn studied at 
Christ Church, Oxford, and while there was con-
verted to Quakerism by the preaching of a disciple 
of George Fox, named Thomas Lowe. His enthusiasm 
for his new faith assumed a pugnacious form. Not 
only did he object personally to attend the services 
of the Church of England, and to wear the sur-
plice of a student—both of which he considered 
eminently poltroonish and unmanly—but in 
the companions who had also become Quakers, he attacked 
several of his fellow-students, and tore the obnoxious 
robes from their backs. For this unseemly 
procedure Penn was expelled from the university. 
His father was so excessively annoyed at his 
conduct that he determined to expel him from the 
home; but he soon afterwards relented, and 
sent his son to travel on the Continent, in the hope 
that change of scene and the gaiety of French life 
would alter the bent of his mind. They failed, 
however, to effect this, but the youth certainly 
acquired a great insight into the privileges of life. 
When he returned to England, 1666, he again 
fell in with Thomas Lowe, and for attending 
Penn, and his father again quarrelled, because the 
'conscience' of the former would not allow him to 
take off his hat to anybody—not even to the king, 
the Duke of York, or the admiral himself. Penn 
was again turned out of doors by his father testy, 
but assuredly provoked parent. The matter, how-
ever, stepped in, and smoothed matters so far that 
Penn was allowed to return home, and the admiral 
even exerted his influence with the government 
to wink at his son's attendance at the illegal 
convictions of the Quakers, which nothing would 
induce him to give up. In 1668, however, he 
was thrown into the Tower, on account of a publication 
entitled The Sandy Foundation Shaken, in which 
he attacked the ordinary doctrines of the Trinity, 
and was 'satisfied.' The death of Charles II., in the death of Christ, and jus-
tification by the imputation of righteousness. 
While in prison he wrote the most famous 
and popular of his books, No Cross, no Crown, 
and Innocence with her Open Face, a vindication of 
himself that contributed to his liberation, which 
was obtained through the interference of the Duke 
of York. In September 1670 Admiral Penn died, 
leaving his son an estate of £1500 a year, together 
with claims upon government for £10,000. In 1671 
the upright but incorrigible sectary was again 
committed to the Prison for preaching; the 
Convictute Act did not touch the case, but, as he refused to
take the oath of allegiance, he was sent to Newgate for six months. Here he wrote four treatises; one of them, entitled The Great Cause of Liberty of Conscience, made his name widely known. After regaining his liberty he visited Holland and Germany for the advancement of Quakerism. The Princess-Palatine Elizabeth, the granddaughter of James I., showed him particular favour. On his return he married, in the beginning of 1672, Guiliana Maria Sufet, daughter of William Springett, and for some years thereafter continued to propagate, by preaching and writing, the doctrines of his sect.

Circumstances having turned his attention to the New World, he in 1681 obtained from the crown, in lieu of his monetary claim upon it, a grant of territory in North America. Penn wanted to call it Sylvania, on account of its forests, but the king (Charles II.) insisted on the prefix Penn in honour of his father. His great desire was to establish a home for his co-religionists in the distant West, where they might preach and practise their convictions in un molested peace. Penn, with several friends, sailed for the Delaware in September 1682, was well received by the settlers, and in October held his famous interview with the Indian tribes, under the auspices of his secretary, Adams, after the death of Kensington, and now a part of Philadelphia. He planned and named the city of Philadelphia, and for two years governed the colony wisely and well, but on strictly Puritan principles. Not only Quakers, but members of other religious sects sought refuge in his new colony, where the first the principle of toleration was established by law.

Towards the end of the reign of Charles II. Penn returned to England to exert himself in favour of his persecuted sect. His influence was not inferior to that exercised by James II.—an old friend of his father's—was so great that many people have never felt quite satisfied about the nature of their relations. The suspicion, however, that Penn allowed himself to be used as a tool by the court is not justified by any known facts, and the charge was based on an ungracious animosity which has urged the view of his complicity in some of the disgraceful incidents that followed Mompesson's rebellion—has been convicted of insubordination and inaccuracies in several important particulars. At any rate, his exertions in favour of the Quakers were so far successful that in 1686 a proclamation was issued to release all persons imprisoned on account of their religious opinions, and more than 1300 Quakers were set free. In the April following James issued an edict for the repeal of all religious tests and penalties, but the mass of Nonconformists mistrusted his sincerity, and refused to avail themselves of it. After the accession of the Prince of Orange as William III. Penn was twice accused of treason, and of corresponding with the exiled monarch, but was acquitted. In 1690 he was charged with conspiracy, but was not arrested. Nevertheless, in the following year, the charge was renewed. Nothing appears to have been done for some time, but Penn at last, through the kindly offices of his friends, Locke, Tilloston, and others, had the matter thoroughly investigated, and he was finally and honourably acquitted in 1693. In 1692 he had been deprived of his government, but it was restored to him in 1694. In the latter year his wife died, and Penn published a memoir testifying to her great virtues: but in less than two years he married again, his second wife being Harriott Callowhill, of Bristol, a Quaker lady. In 1699 he paid a second visit to the New World, where Pennsylvania required his presence to restore peace and order after the arbitrary behaviour of his deputy. His stay, which lasted two years, was marked by many useful measures, and by efforts to ameliorate the condition of both the Indians and Negroes. He departed for England towards the end of 1701, leaving the management of his affairs to an agent, whose villainy virtually ruined Penn. When the rogue adopted all the claims against his master, which Penn refused to pay, allowing himself to be thrown into the Fleet in 1708. His friends afterwards procured his release, but not till his constitution was fatally impaired. After six years of his life his memory and understanding were greatly weakened. He died at Ruscomb, in Berkshire, July 30, 1718.

To the proprietors of his descendants were bought up by a pension of £4000, which in 1884 was commuted (see PENSIONS).

See Macaulay's History of England, and J. Paget's Inquiry into the Evidence of the Charges brought by Lord Macaulay against William Penn (1858); the Life prefixed to his collected works (2 vols. 1729), and to later issues of 'select works,' and Lives by Clarkson (1840), Heworth Dixon (new ed. 1856), Robert J. Burdett (New York, 1882), and Stoughton (new ed. 1888).

Pen-names. See PSEUDONYMS.

Pennant, Thomas, traveller, was born of a good old Welsh family at Downing, near Holywell, Flintshire, in June 1726, and was educated at Wrexham, Flintshire, and Haverford. In 1744 he went up to Queen's College, Oxford, but he left without taking a degree, having meanwhile, in 1746, ridden down into Cornwall—the first of his many tours. These included visits to Ireland (1754); the Continent (1755), where he made the acquaintance of Buffon and Voltaire; Scotland (1769 and 1772), which 'was then,' he says, 'almost as unknown as Kamchatka, but ever since has been inundated with southern visitants;' and the Isle of Man (1774), besides rambles through England and his native province. Ten times, in 1759 and 1777, was made member of the Royal Society of Upsala, an F.R.S., and a D.C.L. of Oxford; and died at Downing, 16th December 1798. From boyhood a naturalist, for years a correspondent of Linnaeus. Pennant published British Zoology (1765-77), British Quadrupeds (1771), Arctic Zoology (1780), History of London (1790), &c.; but to-day he is chiefly remembered by his Tours in Scotland (3 vols. 1771-75) and Wales (2 vols. 1776), in which works extorted from Johnson the admission: 'He's a Whig, sir, a dog; but he's the best traveller I ever read; he observes more things than any one else does.' See the amusing Literary Life of the late Thomas Pennant, Esq., by Himself (1783), and the memoir prefixed to Professor Raly's edition of the Tours in Wales (3 vols. Carnarvon, 1883).

Pennatula, an interesting animal whose quill or feather-like appearance is suggested by the term, and by the popular name Sea-pen. It is one of the Aelurocanian Actinizon, in the same sub-class as Dead-men's Fingers, Red Coral, Gorgonia, &c. One species ("P. phosphorea") is found at moderate depths (e.g. 20 fathoms) round British coasts. It consists of a basal stalk, by which the animal is probably fixed upright in the mud, and of a free axis bearing numerous polypes. The whole length is about 4-5 inches; the colour is
Pennine Alps. See ALPS.

Pennon, a small, pointed or swallow-tailed flag, borne by a medieval knight on his lance. For pennant, as well as pecon, see FLAG.

Pennsylvania, a state of the American Union, since 1830 the second in population, is in shape parallelogram, lying almost entirely between 42° and 30° 43' 26" N. lat. (Mason and Dixon's Line, q.v.), and between the irregular W-shaped Delaware River and 80° 31' 30" W. long. It is about 190 miles wide and 302 miles long from east to west; in area (45,215 sq. m.) it is the twenty-eighth state of the Union. In the north-western corner a triangular section extends to 42° 13' N., forming part of the western boundary of New York, and giving Pennsylvania about 45 miles of coast on Lake Erie, with an excellent harbour at Erie.

The Appalachian (q.v.) system of mountains crosses Pennsylvania from north-east to south-west. It here attains its greatest breadth, but none of the ridges reaches any great altitude, though a few peaks among the Alleghanys attain a height of more than 2500 feet. Between the Blue or Kittatinny Mountains on the east and the higher Alleghany range on the west lie numerous minor forested chains, interspersed with picturesque valleys, many of them rendered exceedingly fertile by the limestones which underlie their soiL The surface of the state is naturally divided into three sections, the low district south-east of the mountains, the mountainous region, and the broken hilly plain to the west. The triangular south-eastern part of the state consists of a narrow level plain near the Delaware River, with an elevation of not more than 100 feet above the sea, merging into a higher rolling region which extends to the base of the mountains. From Canada to the southern limit of the Appalachians extends an almost continuous valley, lying east of the main ranges, and separated from the coast region by the skirting south-eastern ridge. This 'great valley' is through-
northern fields; the resources of the anthracite mines are estimated as sufficient to yield 100,000,000 tons per year for two centuries. Coal production during the decade 1888-98 averaged about 45,500,000 tons. Pittsburgh is the centre of the bituminous region, and the average annual production for the same period was 39,265,977 tons. The proximity of coal and iron in such vast quantities has made Pennsylvania the leading state in coal and iron works, and leads in the manufacture of pig-iron, yielding over 4,600,000 tons in 1897, nearly one-half the total output of the United States.

The successful boring for Petroleum (q.v.) in 1859 predicted the rapid development of Pennsylvania, which was encouraged even by the discovery of gold in California. Fortunes were made and lost in a day. The mining of petroleum and the manufacture of the various articles produced from it have created new and important industries. The utilisation of natural gas for heating and manufacturing purposes has also greatly modified methods of living in western Pennsylvania. Gold, silver, copper, and tin exist in Pennsylvania, but not in paying quantities, though copper is mined to a limited extent in Montgomery county. There are large zinc-works at Lycoming, and nickel is obtained in Lancaster county.

The eastern part of the state is drained by the Delaware and its tributaries the Schuylkill and Lehigh. The Susquehanna, with its affluent the North Branch, the West Branch, and the "beautiful" tributary Juniata, is still second in extent. The Susquehanna is too rapid and too shallow for navigation, but it is used for floating quantities of timber, and coal, lumber, and other products are carried by the canals along its banks. A portion of the north-western region belongs to the valley of the Ohio, which through the greater part of western Pennsylvania is drained by the Allegheny and Monongahela rivers, which unite at Pittsburgh to form the Ohio, furnishing a great highway of inland navigation. Pennsylvania has (1897) 9865 miles of railroad and several hundred miles of canals.

The 'Pennsylvania system,' as described, has enormous financial and educational resources, subject to extremes, and much modified by differences of elevation. Heavy snows fall on the mountains in winter, and the rivers of the western half of the state are often flooded in spring and summer (see e.g. Johnstown). Nearly one-fourth of the state is wooded; lumbering is one of the sources of wealth in the north, and farther south and west are great forests of hemlock, which maintain some of the largest tanneries in the world. In the Pocono swamps and plateaus, between the Wyoming and Kittanning Mountains, the virgin growth of beech is known as the 'Shades of Death.' The soil, except in the mountains, is rich and fertile. Agriculture is a leading occupation, and in many crops Pennsylvania holds a high rank. The mountain regions and the western plateau are well suited for grazing. The cattle and dairy products are noted for their excellence. The most important industries of Pennsylvania are mining and manufacturing. The amount of capital invested is greater than in any other state, and in the value of her manufactured products Pennsylvania is surpassed only by New York. Her commerce, both foreign and domestic, is very extensive. Shipbuilding is important; river steamers are built at Pittsburgh, and iron and steel steamships, including some of the finest war-vessels in the United States and other navies, are constructed on the Delaware river, the 'Clyde of America.'

History.—The first permanent settlement in the state was made in 1643 by Sweden, at the present site of Chester. The colony of New Sweden was first, twelve years later conquered by the Dutch. In 1664 the English obtained possession, and the territory now called Pennsylvania was in 1681 granted by Charles II. to William Penn (q.v.). The friendly relations already existing between the states were established by Penn by a treaty, which was faithfully observed by both parties for more than fifty years. During the French and Indian wars, however, and again during the war of the revolution, the frontier settlements were in constant danger of attack. The great sargasso navigable even by the discovery of the Delaware, the Hudson. The public schools now are attended by over a million pupils, and there are more than twenty universities and colleges in the state. A system of Soldiers' Orphan Schools was established in 1863, and there are numerous other charitable and educational institutions. The German agriculture is a prominent element in the population; many of the miners and ironworkers, especially, are of Irish, Hungarian, and Italian birth, and serious riots have not seldom occurred (see also Molly Maguires). Among the farmers a very large proportion are of German stock, and still speak the patois known as 'Pennsylvania Dutch.' This belongs to the South German dialects, and is most closely related to the Pfalzisch; it preserves many old and curious German words, but is also interspersed with English words of German derivation, according to the locality. There are perhaps two million people around Philadelphia and New York who speak the patois; and in the country southwest in the Alleghanies they have their own dialectal newspapers. Specimens (spelt phonetically) of the dialect may be given: 'Ich trink trunken, rooter wel' (I generally drink red wine); and 'a wetter iss dr gants dank sehse gwest' (the weather has been fine the entire day). See Prof. S. S. Haldeman's Pennsylvania Dutch (1872); also A. J. Ellis's Early English Pronunciation (part iv. 1872).

The state contains sixty-seven counties, and consists thirty-two members to congress. Pennsylvania, the metropolis of the state, is the leading manufacturing city of the Union and ranks third in population (1,325,697 in 1900). The important cities are Pittsburg (321,618) and Allegheny (129,806), which form in all their interests a single community, Harrisburg, the capital (50,167), Seranton (102,626), Reading (78,961), Erie (52,733), Wilkesbarre (31,721), Lancaster (41,439), Altoona (38,973), Johnstown (33,898), Allentown (33,410), M'Keasport (34,227), Chester (33,983), York (33,708), Williamsport (28,575), &c. Pop. of the state (1850) 2,311,786; (1890) 5,288,014; (1900) 6,302,115.

Pennys.—A. pennys or pending; apparently from pund, 'a pawn,' Ger. pund, Lat. pannus, a British coin, equivalent to a pound. A single pound, or 20 shillings, is the coin of the King of the West Saxons, about the close of the 7th century. It was at this time a silver coin, and weighed about 222 Troy grains, being thus about 46th of the Saxon pound-weight. This relation to the pound-weight is evidently derived from the usage of the early Franks, who retained the Roman division of the libra into 20 solidi, and the solidus into 12 denarii (the denarius being thus the 240th part of the libra or pound). See Mark. Halfpence and farthings were not coined in England till the time of Edward I., but the practice previously prevailed of so deeply
indenting the penny with a cross mark that the coin could be easily broken into two or four parts as required. Silver farthings ceased to be coined under Edward VI., and silver halfpennies under the Commonwealth. Up to this time the penny had steadily decreased in weight; and under Elizabeth it was finally fixed at 7½ grains of silver, or ⅓ of an old copper penny closely approximated. In 1672 an authorised copper coinage of pence, halfpence, and farthings was established. In 1797 two-penny pieces were coined, but were soon withdrawn. The penny of the present bimetallic coinage, first issued in the end of 1800, is only about half the value of the old copper penny and as metal is worth only about one-seventh of a penny. The German pfennig was also originally a silver coin, bearing the same relation to the German pound of silver as the English penny to its pound. Now the nickel ten-pfennig piece is the ⅔ of the mark. The old Scots penny was only ⅗ of the English one, as the pound Scots and the Scots shilling were also ⅗ of the English coins of the same name. In the 12th century it was made very broad and thin.

Penroyal (Mentha pulegium), a species of Mint (q. v.), a native of Europe and western Asia, abundant in England and in some parts of Ireland, not found wild in Scotland, though sometimes grown there in gardens for its reputed medicinal qualities. It enjoys a high popular reputation as an emmenagogue, but no dependence may be placed in its efficacy. The name penroyal is given in North America to a small plant, Hedema pule-

goides, allied to the mints, and having, like them, a pleasant aromatic smell and a warm pungent taste. It is much in use in domestic medicine, in the form of a warm infusion, to promote perspiration and as an emmenagogue.

Penny Weddings was the name given to festive marriage ceremonies in Scotland at which the invited guests made contributions in money (seldom more than 1s. each), to pay the general expenses, and leave over a small sum, which would assist the newly-married pair in furnishing their dwelling. This practice, more rare than it once was, was prevalent in the 17th century; and, as leading to "profane malversation and promiscuous dancing," was denounced by an Act of the General Assembly, 1615, as well as by numerous acts of presbyteries and kirk sessions about the same period.

Pennywort, a trailing herb (Linaria cymbal-
aria), with roundish reniform leaves, often cultivated in hanging-baskets. Marsh or Water Pennywort is a name used for any species of the umbelliferous genus Hydrocotyle, low herbes with roundish leaves, growing in marshy places.

Penobscot, a river of Maine. The West Branch rises near the eastern limit of the splendid inlet of the Atlantic Ocean, 35 miles long and 20 wide, with numerous islands. It is tidal and navigable for large vessels to Bangor, 60 miles from its mouth. The chief trade is in lumber.

Penryn. See Cornwall.

Penrose, a market-town of Cumberland, in a picturesque and fertile valley, of medieval origin, the Church of St. John the Baptist, which is considered the oldest church in the county, and the Church of St. Mary, which is the most ancient in the country. The town is situated on a high hill, and is surrounded by a wall of stone, with gateways and towers.

Penryn, a town of Cornwall, at the mouth of a river, which is navigable for small vessels, and is connected with the sea by means of a lock. It is a port of call for the West India trade, and is celebrated for its fine view of the sea and the estuary of the river.

Pennsylvania, a state of the United States, and one of the original states. It is bounded on the north by New York, on the east by Delaware, New Jersey, and New York, on the south by Maryland and Virginia, and on the west by Ohio. It is a large and fertile state, with a population of about 9,000,000. It is divided into 67 counties, and its capital is Harrisburg.

Pennsly, a port of entry and the capital of Pennsylvania, is 244 miles by rail from New York, on the west shore of a deep bay opening into the Gulf of Mexico. The entrance is defended by Fort Moltke and Fort Pickens, the latter on Santa Rosa Island; and near by is the Pensacola navy-yard, with a marine hospital and barracks. Pensacola contains fountains and lumber and planing mills, and ships large quantities of yellow pine. It was settled by the Spaniards before 1700, occupied by the British from 1763 to 1781, and afterwards during the wars with Napoleon, taken by Andrew Jackson from the British in 1815, and the Spaniards in 1818, and passed with the rest of Florida to the United States in 1819. Pop. (1880) 6845; (1900) 17,477.

Penshurst, a village of Kent, 4 miles S.W. of Tunbridge; pop. 1673. Penshurst Place was the birthplace of Sir Philip Sidney and Algernon Sidney.

Pensions, the name formerly given to the annuity or legal adviser in every important town of Holland, because receiving a salary or pension; and, during the republic of the United Netherlands, the state secretary for the province of Holland was called "Pensionarius."—Englished by State Pensioner, no pensioner, no pensions, no pension of the province, and whatever else pertained to its welfare. The office was abolished in 1795, after the conquest of Holland by the French revolutionists. Olden Barnewelt, De Witt, and Hein-sins were the most celebrated holders of this office.

Pensions may be broadly divided into two classes, those for the general service, and those for special services. In Great Britain a sum of £1,500,000 per annum is required for superannuation in the various departments of state, including
PENSIONS

33

The consular, diplomatic, and colonial services. The number of consular pensions in 1884 was 399, 3258, and the grants for them are in the estimates classed among 'Non-effective and charitable services.' The pensions granted from the Civil List (q.v.) are altogether on a different footing from those in the civil service, which last are part of the condition of employment. The Civil List grants were in 1886 a somewhat in the nature of deferred pay. Of the same nature is the retired pay of army and navy officers, as well as the service-pensions to soldiers and seamen. Pensions to the widows and children of deceased servants of the state are often granted under the terms of the act of Parliament. The most prominent character of the burden of the non-effective services has given occasion for much discussion, and has called forth many suggestions. Thus, in the session of 1884 a motion was carried in the House of Commons, the effect of which is to restrict the system of compulsory retirement on pension of civil servants. The principle has been laid down that officials no longer required in their own departments who are still able and willing to render service for the public money should be provided with employment in other departments, instead of taking pensions upon retirement from the public service. The principle was adopted, which, after taking evidence of a curious and interesting kind, recommended that no more pensions or allowances should be granted in perpetuity. This committee also reported in favour of the abolition of all sinecure offices with salaries but no duties, and recommended that all existing perpetual pensions, allowances, and payments, and all hereditary offices, should be determined and abolished. In commutation such pensions it has been laid down as necessary to differentiate cases of grants for actual services by the original grantees, and cases of mere gratuity. Where no service or merely nominal service was rendered either by the present holder or the original grantee it was proposed that the payment should in no case continue beyond the life of the present holder. In future applications of perpetual pensions a scale of twenty-seven years' purchase was usually adopted. On or about this scale there were, between 1881 and 1887, 330 pensions and allowances of the annual value of £18,597 commuted for a sum total of £257,953. The rate was reported to be too high, and in the session of 1888 a motion was passed for giving effect to the recommendation of the select committee, and for a return in detail of all outstanding hereditary pensions and the circumstances in which they were granted. Pensions such as those of £4000 per annum to the Duke of Marlborough, and of £5000 to Lord Nelson, and to their heirs in perpetuity, are, of course, well understood as in return for 'value received' in special services to the state. The objection to the principle of them is that it is a burdening of posterity with expenses renders the nation dependent. The rewards for distinguished services should be defrayed by the generation receiving the benefit of them, and should be conferred upon the persons who actually render them, either in the form of a capital sum down, or of a life-pension only.

There are, again, a number of hereditary pensions conferred not for services, but as solutisim for the loss of the fees of abolished offices. Thus, when the offices of Custos Breivium and Clerk of the Juniers were abolished in 1837 the holders were compensated with hereditary pensions of £786 each. These were commuted on a basis of twenty-seven years' purchase. One of the numerous perquisites conferred by Charles II. upon his favourite, the Duke of Grafton, was that of Office of the Pipe, or Remembrance of First Fruits and Tenths of the Clergy in the Court of Exchequer. This office was sold by the duke in 1765, and when the fees were abolished the holder was compensated with a perpetual pension of £391, 1s. 3d., as salary, £200 for four falcons, £600 for provision of hawks, and £100 for a tent which, for other similar purposes. The case of the hereditary office of Master of the Hawks, granted by James II. to the Duke of St Albans and his heirs for ever. The emoluments consisted of £301, 1s. 3d., as salary, £200 for four falcons, £600 for provision of hawks, and £100 for tenths as above, for the period of 18 years. The total was subsequently reduced to £265, and at which it stood until commuted, in 1891, for £18,335, although there had been neither hawks nor falcons for many generations. A pension of £4000 per annum granted in 1779 to William Penn, the founder of Pennsylvania, and his heirs for ever, was in 1884 commuted for a ten years' annuity of £12,796, considered equivalent to twenty-seven years' purchase. In 1876 Charles II. granted to the Duke of Richmond and his heirs for ever a duty of one shilling per ton on all coals exported from the Tyne for consumptive purposes. The Duke of Hamilton, as hereditary proprietor of the hereditary pension of £45, 10s., and the descendants of the Heritable Usher of Scotland enjoy one of £242, 15s. These are a few of the examples of a wholly indefensible system. There are also limited hereditary pensions allowed for a certain number of lives, which are not so unjustifiable, as, for instance, the pension of £4000 to the Duke of Wellington and two successors, and the pension of £2000 to Lord Napier of Magdala and one successor. In 1891 there were eight of these limited hereditary pensions in existence (viz. Lords Combermere, Gough, the Heritable of Scotland, Keane, Napier, Raglan, and the Duke of Wellington), most of which were in the possession of the last holder. It is probable that this system of reward for military services will also be discontinued. Pensions, but for life only, may be claimed by ministers who have held office under the crown (not necessarily continuously) for four years in the first class (£2000), six years in the second class (£1200), or ten years in the third class (£500). The following is a summary of the total amount paid by Great Britain in pensions, superannuations, and compassionate allowances: we take the figures for the fiscal year 1887-88, because that period coincides with the movement to terminate perpetual pensions:

In round numbers the present outlay of the government of the United Kingdom in pensions and superannuations is about 7½ millions per annum, of which quite 5½ millions go to the army and navy, and form a partial provision for the national defence, although probably capable of better distribution. It is an open question how far the remaining 2 millions may be wisely expended, but for hereditary allowances the national accounts will not incur fresh charges, and existing charges are being equitably extinguished. On the Indian List there are set down 10,500
PENSIONS

pensioners drawing £6,000,000, of which £2,500,000 belongs to the civil and £3,500,000 to the military department.

ARMY PENSIONS are temporarily granted to officers of the army severely wounded in action at the following rates, and if the wound is so serious as to entail a permanent injury, the pension may be made permanent: Field-officer, £100 a year; major-officer, £75; lieutenant-colonel, £50; captain, £25; and a lieu-
tenant, £20. These pensions may be held together with retired pay (see RETIREMENT). If an injury of similar character is received on duty, but not in action, a general officer receives a special rate of pension; a colonel or lieutenant-colonel, £250 a year; a major, £150; a captain, £75; and a lieutenant or second-lieutenant, £50. Pensions are also granted to the widows of officers dying in the service, at rates varying from £40 a year in the lowest rank to £120 in the highest, subject to an increase of 50 per cent. if the widow is a pensioner in the Forces. A special allowance (£10 to £20, according to rank) is granted to their sons if under eighteen, and to their daughters if under twenty-one, increased by 25 per cent. if the father is killed in action. On re-
marrriage a widow forfeits her pension, but on age of sixty she may be restored if her case is deemed to be one of necessity. If the mother or sisters of an officer killed in action were dependent upon him, com-
passionate allowances may be granted to them.

Warrant officers, after more than twenty years’ service, may receive a pension varying from £8, 6s. to £40 a year, according to length of service, their widows £20, and their children £5 a year, with certain limitations.

Non-commissioned officers and soldiers, whether European or natives, are classed for pension accord-
ing to rank and service in that rank, the highest daily rate being 2s. 9d. and the lowest 6d. No soldier of less than fourteen years’ service is entitled to a pension, except for injuries sustained in action or on duty, when the rates vary from 6d. to 3s. a day, according to rank, service, extent of the injury, and character of the wounds, and the pension is not made permanent until a medical board has pronounced the injury to be a permanent disability. A special pension, in addition to any other, of £10 a year is granted to every soldier who has gained the Victoria Cross, and an addition of £5 is granted for each subsequent decoration of the order. Medals, with annuities not exceeding £20, are granted to soldiers above the rank of corporal who have performed distinguished or meritorious services, and are selected by the commander-in-chief. These annu-
ties are in addition to pension.

NAVY PENSIONS were first instituted in the reign of William and Mary; those for officers may be classed as follows: Good-service pensions, Green-
wich Hospital pensions, pensions for wounds, and the ordinary pension to which an officer may be entitled on retirement, now known as retired pay. No officer is entitled to retired pay until he is forty years of age; should he retire earlier he receives merely the half-pay of his rank. The amount of the retired pay depends upon an derived officer’s rank, length of service, and age. The maximum retired pay of a midshipman is £30 a year, of which thirty years’ sea-service as a commissioned officer is requisitible; he may in addition hold a good-service pension of £300 a year. The maximum retired pay of vice-admirals, with twenty-nine years’ service, is £500 a year; that of rear-admirals, with twenty-
seven years’ service, £400; captains, with twenty-seven years’ service, £600; of commanders, with twenty-one years’ service, £400; and of lieu-
tenants, with nineteen years’ service, £300. The retired pay of officers of other branches of the service is calculated in the same way, on length of service and age. The good-service pensions, sub-
collected, consist of ten of £300 a year for admirals, which amount to a pension of £150 a year for captains; these last are conferred on captains on the active list, and are relinquished when their holders are promoted to rear-admiral or retire. Pensions for wounds are conferred on officers and men; they range from small yearly allowances, according to rank of holder, to £150 a year, to a maximum of £200 a year.

All seamen and marines are entitled to a pension after twenty-one years’ service from the age of eighteen, or from the date of enlistment; this pension ranges from 10d. a day to a maximum of £12. 2d. a day, the increase depending upon the number of good-conduct badges a man may have; of these he may have three, and he receives an additional 1d. a day for each, and, if he holds a good-conduct medal, an additional penny for that.

Petty officers, in addition to the rates of pension already detailed, are entitled to a pension ranging from £25 a year in the case of superior petty officer 1st, £21. 1d. a year, as junior petty officer 7th, 7d. There still remain the Greenwich Hospital pensions, which are held in addition to the ordinary pensions. The idea of establishing a hospital for infirm and disabled seamen originated with the beneficence of William III., and Sir Christopher Wren was employed to build an additional wing to Greenwich Palace. The king granted £2600 a year towards it, large subscriptions were added by noble and wealthy people, forfeited and unclaimed prize-money and various grants were given, and finally the forfeited estates of the Earls of Derwentwater were added to the endowment. The revenue of the hospital is now about £167,000 a year. The Greenwich Hos-
pital pensions are divided as follows: Ten of £150 a year for admirals, six of £80 a year for captains, twenty-three of £65 for commanders, and forty-six of £50 a year for lieutenants; three of £80 and seventeen of £50 a year for officers of the old navigating branch, and fifty-seven varying from £100 to £50 a year for officers of the civil naval branches of the service. There are fifty-two of £5 and £25 a year for pensioners in the Forces, and several pensions for the men termed 'age' and ‘special’ pensions. They are given entirely at the discretion of the Admiralty, and are not granted to any per-
son whose character whilst in or after leaving the navy has not been good. A naval pensioner is entitled to a half-pay killed in 6d. a day on attaining the age of fifty-five, if he has been in receipt of his pension for five years; and for the increase of such age pension to 9d. a day at the age of sixty-
five, if he has been in receipt of his naval pension for ten years. Age pensions are given to naval pensioners, and the number of men in force at any one time is not to exceed 7500; the vacancies to be filled by those whose health renders them completely incapable of earning a living.

Special pensions are given at the discretion of the Admiralty to men unable to contribute ma-
terially to their own support, and vary in amount and duration according to each man’s degree of disability and the other circumstances of his case; the amount of the fund from which these pensions are given is limited to £22,000 a year. They are available in addition to naval and age pensions; these pensions range from £5 a year.

Widows of officers of royal navy and marines are allowed pensions, and their children compassionate allowances. These cannot be claimed as a right, and, except in the case of pensions conferred on widows of officers killed in action or dying from wounds or other special causes, are not granted to
PENSIONS

PENTATEUCH

widows whose private incomes may exceed a certain scale which is fixed by the Admiralty. These pensions in ordinary cases range from £120 to £40 a year. In the case of officers killed in action their widows, having no other income, may receive a weekly allowance not exceeding £200 a year. Compassionate allowances to children may be continued in the case of sons until they attain the age of eighteen, and of daughters until they marry or attain the age of twenty-one, but no longer, except in very special cases. These allowances vary, according to the length of time they have been in the pensions, and compassionate allowances are made to widows and children of petty officers and men at the discretion of the Admiralty, but there is no fixed scale.

The Pension System of the United States presents two peculiar features, in the almost entire absence of a civil list, and the non-recognition of long service as a ground for pension. Generally speaking, pensions are granted only for active service in time of war, and therefore the beneficiaries are the survivors (or their widows and children) of the armies of volunteers and conscripts who took part in the country's several wars. What are called 'service pensions' have been granted to survivors of the War of the Revolution (under Act of 1818); the last pensioner under this act died in 1867, aged 101. Widows of volunteer or conscripted soldiers, however, under a special act, not till 1869, aged 109), the War of 1812 (under Act of 1871), and the Mexican War (under Act of 1887), or to their widows (37 survived in 1888). But the bulk of the United States pensions are 'invalid pensions,' for total or partial disablements incurred in the service; the military or naval service; the widows and minor children under sixteen years of age of those who have died from such wounds or disease; or, in the event of no such widows or minor children surviving, then the dependent mothers, fathers, or minor brothers and sisters of officers or men so dying. The pensions, which range from $24 to $2000 per annum, are graded, and many specific wounds and disabilities are scheduled and priced. Thus, where the regular aid and attendance of others is required, from $50 to $72 a month is paid; where the labor of a car- riary for manual labor, $30 a month; for the loss of a hand or foot, or total deaf- ness, $30, but of both feet or hands, or both eyes, $72 a month; and for amputation at the shoulder or hip joint, $45. Widows of privates receive $12 a month, and $18 for five-eighths of the salary of a captain or major. The salary is $12 a month, but if the widow does not survive they receive their pension jointly. Widows or dependent relatives of officers receive from $15 to $30 a month. The pension of widows ceases when they marry. For the administration of the pension system an independent bureau was created in 1833; since 1849 it has been a bureau of the Department of the Interior. Under the commissioner, who is appointed by the president, there are nearly 2000 persons employed in the settlement of claims for pensions; and besides there are nearly 3000 sur- gardeners throughout the country engaged in examining applicants. The following figures show plainly enough the enormous growth of the American pension system. In 1862 the disbursings slightly exceeded $790,000; in 1872 they exceeded $30,743,542; in 1882 $64,000,669; in 1888 $87,000,000; in 1889 $136,634,989; in 1897 the total was $130,594,717 (the pensioners numbering 2670,014, and from 1866 to 1897 the amount aggregated $2,106,904,441; while under the Dependent Pension Law passed in June 1890, 460,282 claims were received in 1893 alone). The numbers increased over one-third the revenues of the republic (while 500,000 claims were still awaiting adjudication), and the Spanish-American war (1898) gave rise to numerous claims for disabilities.—It may be added that, by an Act of 1882, widows and minor children of keepers or crew of a life-saving or life-boat station who perish in or from injuries received through the life-saving service are given the full pay of the deceased for two years.

Pentacle, or Pentagram, a five-pointed figure of the form shown in the annexed illustration, which occurs on old Greek coins and was used as a symbol of mystery, perfection, or of the universe by Pythagoreans, Neoplatonists, and Gnostics. It occurs on mirrors of Ancient Rome, and was used as the device of various secret societies, some of them masonic, and hence appears in ecclesiastical architecture (as at Rouen). The 'wizard pentagram' was, in the middle ages, a symbol powerful in repelling evil spirits, and is familiar to readers of Goethe's Faust. On the doors of cow-houses it was held to keep off witches. The pentacle, also called pentalaphus, is often confused with the hexagram, composed of two equilateral triangles, which was also used as a magic symbol in astrology, alchemy, and cabalistic lore. See Circle (Magic).

Pentacrinia. See Crinoidea.

Pentamerone, a famous collection of fifty folktales, written in the Neapolitan dialect, by Giambattista Basile, which are supposed to be told during five days by ten old women for the entertainment of a Moorish slave who has usurped the place of the rightful princess. An admirable German translation (enriched by notes by Felix Liebrecht) appeared at Breslau in 1848. Thirty-one of the stories were translated by J. E. Taylor (1845); Sir Richard Burton printed a complete English translation in 1893 (2 vols.) (For the Decameron and the Heptameron, see Boccaccio, Margaret of Navarre). The Pentamerone stories are of the greatest value to the student of folk-tales.

Pentamerons, Beds, in Geology, a name formerly applied to the upper and lower Llandover rocks, owing to the abundance of the brachiopods called Pentamerus. See Silurian System.

Pentapolls. See Cyrenaca.

Pentateuch, a Greek word (penteuteuchos) meaning 'the five-volume (book),' is the name used by Origen to denote what the Jews of his time called the 'law' (Torah) or, more fully, the first five books of the Pentateuch. The word was adopted into the Latin by Tertullian. 'The five books of Moses' as a designation of the Pentateuch was first made current in the Western Church at a considerably later period by Jerome and Rufinus; but a Jewish writer (Josephus) had long before stated that the first five books of the Old Testament canon 'belong to Moses.' The Greek names by which the five books are now known—Genesis, Exodus, Levitius, Numbers (Aristhmoi), Deuteronomy—have come to us from the Septuagint through the Vulgate Latin. Along with the books of Joshua these five really form one continuous work, now usually referred to by modern scholars as the Hexateuch, the present division of the Hexateuch having been made by a comparatively late editor. The Mosaic authorship of the Pentateuch is nowhere affirmed in the books themselves, but it is suggested by certain obvious phenomena in various parts of them, though contradicted by others; and it had begun to be held before the Jewish canon was closed (the law of Moses,' that is, the first book of the receiving its final form). See also Books, xxv, 4, xxx, 12). It soon became a fixed ecclesiastical tradition and a tacitly established point of Christian orthodoxy, and those who doubted or denied it were generally held to be, and in fact often were, hostile to Christianity (Hobbes, Spinoza),
though this cannot be said of Leclerc, Simon, or Morinus. The facts which have generally led scholars with steadily increasing unanimity to a contrary conclusion have already been indicated under (L); where the leading documents—JE (Jahvist—Elohist), D (Deuteronomy), and P (Priests—history and Priestly legislation) have been numbered as underlaid, the present article will seek to describe these documents with rather fuller detail and to indicate briefly what is maintained by many modern critics as to the nature of the somewhat complex process by which they have reached their present state of condition.

(1) JE. This is compounded mainly from two older parallel narratives, both of which embodied in writing current oral tradition relating to the origin of the world and of man, and to the patriarchal and heroic periods of Hebrew history. The extent of the document as we now have it may be ascertained roughly by deducting D and P (see below) from our present Hexateuch, allowance being also made, however, for editorial additions and glosses. The separation of its two constituent elements is a problem of great difficulty and discussion. We may call the book of the Jahvist, which employs the name Jahweh (see Jethovith) throughout, is distinguished also, on the whole, by other well-marked characteristics, especially a naive anthropomorphism, which appears more particularly in the narratives of the patriarchal epoch, under the form of 'the angel of Jehovah,' as, for example, to Abraham, to Lot, and to Moses at the inn and also on Piagah. The style is lively, vivid, and popular. The author shows special interest in the local sanctuaries which were still recognizable in his own time, showing that they owed their origin to the theophanies in the pre-Egyptian period. His dialect is that ancient and simple form of the law contained in Ex. xxxiv. He introduces, at various places, extracts from older poetical works, such as Gen. xlix. and the quotations from 'the book of the wars of Jehovah.' For minute details as to the limits of his work reference must be made to some of the books mentioned in the bibliography appended to this article, among the more important passages in Genesis which can with considerable certainty be attributed to him are the account of the procreation and fall in ii. 4-4 iv. 26; portions of vi.; one of the two parallel accounts of the flood contained in vii. viii.; the history of Abraham in xii. xiii. xv. xvi. xvii. xix. xx. xxiv. of Isaac in xiv. 21-34, and the greater part of xxii., of the story of Jacob, including one of the narratives which make up chap. xxxiv.; portions of xxxvii., the story of Judah (xxxviii.); the story of Joseph in xxxix. xl. xli. xlii. and l. (also some fragments in the intervening chapters). (2) The Elohist, who in the book of Genesis invariably employs the name Elohim, has several distinguishing characteristics. He shows some beginnings of a tendency to remodel the ancient traditions in a less anthropomorphic sense. He does not speak of objective manifestations of the Deity by visible signs, but he is more likely to represent divine communications as being by dreams, visions, and voices. It has been remarked that he takes a special interest in the sanctuary of Beer-sheba. His dialect, if later explanations be left out, is contained in Ex. xvi. He has no doubt originally had an account of the creation and fall parallel to that of the Jahvist, but the earliest extant fragment of his work is probably that preserved in Gen. xv. 5. To him are attributed Gen. xx. 1-17, xx. 6-32, xxx. 4-14, xxxi. 1-31, xxxii. 36-43, xxxiii. 1-20, xxxiv. 1-20, and xxxv. 1-7. These portions of the remaining chapters; Ex. i. 6, 8-12, 15-22, ii. 1-10, 15, iii. 1-5, 9-16, iv. 17-23, v. 3, 5-23, vi. 1, vii. 17, 18, 20, 21, ix. 22-26, 31, 32, x. 12, 13a, 14a, 21-29, a few verses of xii. xiii. xvi. 17-19, xiv. 7, 9, 16, 22, xv. 20-23, xvii. 3-10, xviii. 1-4, xix. 10-13, xvii. 19, xxi. 1-23, xxiv. 3-8, 12-14, xlvii. 18, xxxii. 15-20, 25-29, xxxiii. 1-3, 5-11; Num. x. 37-36, xi. 1-3, 7-10, 30-34, xii. 1-15, xi. 20, 29, 24, 30-33, xiv. 39-45, portions of chap. xvi. xx. 3, 11-21, xix. 12 50, portions of the story of Balaam, xvii. 3, 5, xxxii. 16, 17, (also chap. 42); xiii. 41, 42; Deut. xxi. 14-29, xxxiv. 44, xxxxi. 14, xxxiv. 10.

That J and E once existed as separate narratives is now unanimously agreed, and that their dates must be sought somewhere between 900 B.C. at the earliest and 750 at the latest may also be regarded as settled. Within these limits there is considerable diversity of opinion. It is agreed on the whole that E belonged to the northern kingdom, and many hold this of J also, but some of the strongest critics think of the Jahvist as having been a Judæan. There is disagreement also as to the relative antiquity of the Jahvist and the Elohist, the one being older, but the preponderance of argument seems to be in favour of J. The two were brought together into the document now known as JE by a redactor (sometimes called for convenience make the Jahvist, as distinguished from the Jahvist) toward the end of the eighth century B.C. His aim was to embrace the two parallel histories; and his method was simple. Where the two were closely parallel he seems to have chosen the one he thought the preferable and to have cancelled the other (saving occasionally a word or clause); when he found the Jahvist as old as the Elohist, he was willing to support the latter, and in very different forms, such as the incident of Abraham and Sarai at Pharaoh's court, and Isaac and Rebekah at Abimelech's, he gave both, introducing some reconciling notes (e.g. Gen. xxvi. 18). A good example of his manner of combination is afforded by the narrative of Jacob's dream. JE also introduced new matter. In particular, the legislative portion of his work, usually spoken of as the Book of the Covenant (Ex. xx. 24—xxii. xxx. 33, xxiv. 28), shows the influence of the Assyrian period, and (it is held) cannot be earlier than the sixth century B.C., that is, prior to the publication of Deuteronomy.

(11) D. Deuteronomy also is a composite work, and its various elements are not all of the same date. In structure it consists of a legislative redactor to which the close of the original portions is a separate introduction (i. i—iv. 44 and i. vi. 32) and two separate epilogues or concluding narratives (xxvii. and xxviii.—xxx.). Finally, the last four chapters form an appendix containing some materials from J and E. Critics are now generally agreed that the original Deuteronomy to which reference is made in 2 Kings is what we have spoken of as the legislative kernel. The date of its publication we know to have been 621 B.C. That its composition is less certain, but no one now proposes to carry it back to an earlier date than about 600 B.C. There is little doubt as to the authorship, and hence as to the character of the prologue and epilogue. The second introduction and first epilogue, if by the author of the central portion of the book, were probably written at least a century later. The first introduction, recapitulating portions of the two epilogues, containing unmistakable allusions to the exile, are believed to have been the work of a second Deuteronomic writer about the beginning of the 7th century. A third Deuteronomic redactor to the central part of the exile (about 550 B.C.) combined JE with D, and gave what is known as the Deuteronomistic redaction to the
The gradual ascertainment in modern times of the different operations of the Hexateuch is described by Stade with hardly undue exaggeration as one of the most brilliant triumphs of human sagacity. The investigation of the problem on scientific lines may be said to have begun with Astruc (1758), who was the first to point out the value of the 'Jehovah' and 'Elohim' criteria in seeking to trace the authorship of different parts of Genesis. His hypothesis was introduced into Germany by Eliehorn, and was the beginning of a long discussion which has lasted till the present day, producing an immense literature, now for the most part quite out of date, and a vast variety of conflicting and, as was sometimes imagined, mutually destructive theories. The first cardinal fact to emerge from the chaos with clearness was the late date of Deuteronomy as being the new law book which formed the basis of Josiah's reform.

The credit of having established the doubt that the post-Mosaic authorship of Deuteronomy belongs chiefly to De Wette, whose activity dates from 1805. The next thing to be satisfactorily proved was the existence of two independent streams of Elohist and Jehovist, though the feature in common, which had been divined by Igen (1798), but it was always supposed that the one merely supplemented the other, till Hincken (1853) proved their complete independence. In other words, four distinct sources were now completely made out 1) Pre-exilic, 2) Post-exilic, 3) Jehovist, 4) Elohist. The peculiar exilic character of the legislative portion of the Priestly document (hitherto spoken of as the 'Grundschrift' or 'older Elohist'), and it was further shown by Kuenen to the satisfaction of Graf himself that the same character belongs to the Priestly document as a whole. This indeed had been seen and argued for at an earlier date by Vatke (1835) and George (1836), but partly through defects in their manner of presenting their views, and partly because scientific and theological opinion was not yet sufficiently educated to receive it, it failed to make any impression. Renan, Graf's teacher, claimed to have publicly taught the Grafilan theory as early as 1833; but he did not publish it till 1879.

As a manual of modern Pentateuch criticism Kuenen's masterly Historische Kritische Inteile und Zusammenstellung des Hexateuchs, translated from the Dutch by Wickstead (1886), is indispensable to the student, and will probably hold a permanent place as a classical example of the method of modern textual criticism. The 'Introduction' prefixed to it, containing an outline of the history of Hexateuch criticism since 1861 will serve as guide to the older literature. Along with Kuenen's great treatise ranks Wellhausen's equally admirable Composition des Hexateuchs (3d ed., with appendices, 1889). Only the appendices to this work are new, the papers on the composition of the Hexateuch having appeared originally in the Jahrbiicher f. deutsche Theol., in 1876-77, and having been reprinted without modification in 1885.

Valuable assistance of a typographical or mechanical kind is to be found in Kastner's Kritische Bearbeitung Die Genesis mit ausserer Unterscheidung der Quellenabschnitte (2d ed. 1881), in which the various sources and the work of editors and glossators are indicated by the use of differential types. In Kastner's recent new translation of the Old Testament (Die Heilige Schrift des A. T., 1890-91), P, J, E, D, Dt, and R in the Hexateuch are indicated by letters on the margin. See also Loomans, 'Die hexateuchlichen Texte und Einfluss der altorientalischen Handschriften' in the Jahrbücher f. deutsche Theol., in 1876-77, and having been reprinted without modification in 1885.

The gradual ascertainment in modern times of the different operations of the Hexateuch is described by Stade with hardly undue exaggeration as one of the most brilliant triumphs of human sagacity. The investigation of the problem on scientific lines may be said to have begun with Astruc (1758), who was the first to point out the value of the 'Jehovah' and 'Elohim' criteria in seeking to trace the authorship of different parts of Genesis. His hypothesis was introduced into Germany by Eliehorn, and was the beginning of a long discussion which has lasted till the present day, producing an immense literature, now for the most part quite out of date, and a vast variety of conflicting and, as was sometimes imagined, mutually destructive theories. The first cardinal fact to emerge from the chaos with clearness was the late date of Deuteronomy as being the new law book which formed the basis of Josiah's reform.

The credit of having established the doubt that the post-Mosaic authorship of Deuteronomy belongs chiefly to De Wette, whose activity dates from 1805. The next thing to be satisfactorily proved was the existence of two independent streams of Elohist and Jehovist, though the feature in common, which had been divined by Igen (1798), but it was always supposed that the one merely supplemented the other, till Hincken (1853) proved their complete independence. In other words, four distinct sources were now completely made out 1) Pre-exilic, 2) Post-exilic, 3) Jehovist, 4) Elohist. The peculiar exilic character of the legislative portion of the Priestly document (hitherto spoken of as the 'Grundschrift' or 'older Elohist'), and it was further shown by Kuenen to the satisfaction of Graf himself that the same character belongs to the Priestly document as a whole. This indeed had been seen and argued for at an earlier date by Vatke (1835) and George (1836), but partly through defects in their manner of presenting their views, and partly because scientific and theological opinion was not yet sufficiently educated to receive it, it failed to make any impression. Renan, Graf's teacher, claimed to have publicly taught the Grafilan theory as early as 1833; but he did not publish it till 1879.

three separate sections, followed by estimates of the historical meaning of each narrative. Dillmann placed 2
two centuries before the exile; Noldeke and Schürer still place the Parapandit edict late; Baacke states 3
it about thirty years before D. See also Holzinger's Einleitung in den Hexateuch (1883). For a fuller 4
bibliography Renz's Die heiligen Schriften, Alten Testament, 5
(1837) may be consulted. See also articles Bible, Vol. II, p. 128-9; and SAMARITAN PENTATEUCH.

Pentecost (Gr. πεντεκοστή, 'fiftieth') was the name given to the Jewish feast held on the
fiftieth day after the Passover, in celebration of the 'in-
gathering,' and in thanksgiving for the harvest. 6
(See First Sunday.)

From the time it was introduced into the Christian, 7
and with special solemnity, as being the day of the descent of the
Holy Ghost on the apostles, and of the first solemn preaching of the Christian religion.
Early times pentecost has been regarded as one of the
great festivals of the Christian year, and it was 8
chosen as one of the times for the solemn admin-
istration of baptism; and the English name of the
festival, Whit-Sunday, is derived from the white
robes in which the newly-baptised were clad. It
is extensively observed in the Third Person of the
Hallowed Trinity. Many curious usages were
anciently connected with the celebration. The
figure of a dove (an emblem of the Holy Ghost) 9
suspended by a cord from the ceiling was in some
churches lowered so as to alight on the high altar
during the service; in others figures of cloven
lungs were similarly introduced. In some places in
the East, and in the West too, the practice
prevails of decorating the churches with
evergreens and flowers, as is done in England at
Christmas.

Penelecus. See ATHENS (p. 536), and MATT.

Pentland Firth, a channel between the
Atlantic and German Oceans, separating the
Iceland of Scotland from the Orkney Islands. It is
14 miles long and 64 miles broad at the narrowest.
The Pentland Skerries, 5 miles north-east of
Duncansby Head, consist of two islets and of
several contiguous rocks. On the larger of the
islets is a lighthouse (1764). The navigation of
the Pentland Firth is more dangerous than that of
any other portion of the seas, a current from west to east flowing through it with a
velocity of 6 or 8 miles per hour, and causing numer-
ous eddies and whirlpools. Vessels of 2000 tons
with cargoes pass through the Firth annually.

Pentland Hills, in the Lowlands of Scotland,
extend 16 miles south-westward from a point 3
miles south of Edinburgh, through the counties of
Midlothian, Peebles, and Lanark, have a breadth of
4 to 6 miles, and attain a maximum height in
Carnethy (1800 feet) and Scaur Law (1803).
In the battle of the Pentlands or Rullion Green, 2
miles N.W. of Penicuik, Sir Thomas Dalyell routed
900 westland Covenanters, 28th November 1660.

Pentonville, a populous district in London in
the parish of St. James's, Clerkenwell, the first
buildings in which were erected in 1773 on
fields belonging to Henry Penton, Esq. The name
has since been extended to parts of the parish
Islington, in which stands the Pentonville Prison.
This, the Model Prison, as it was at first called,
in the Colstonian Road, was built in 1840-42, and
conforms in every way to the U-shaped or
rotating principle, so as to admit of thorough inspection. It contains accommodation for 520 prisoners. The treatment is designed to 'enforce strict separation, with industrial employment and moral training.' See Report of the Directors of Convict Prisons (periodically).

Pentremites, small Crinoids common in the
Carboniferous System (q.v.).

Pentstemon, a genus of plants belonging to
the natural order Scrophulariaceae, consisting of
herbaceous or sub-shrubby species mostly yielding
flowers of great beauty. The genus is wholly
American, though belonging to the European states
and few of them are hardly enough to endure the
winter climate of Britain, where consequently they
are propagated annually by cuttings, which are
protected in frames during winter and planted in
the flower-garden in March or April. The general
character is a large inflorescence, but, at the same
time, well known as to require no description here.
The numerous garden varieties of P. gentianoides, 10
P. Hortense, and others are among the most popular
of garden flowers. But there are many species
even more beautiful than these, which are occasion-
ally to be met in collections of rare plants. Of
such may be mentioned P. Jeffreynii, P. Secundiflo-
ris, P. Murravenus, P. minutissimus, and others,
as being exceptionally beautiful in colour.

Penumbra. See ECLIPSES.

Penza, a large rural town of Russia, 330 miles
by rail SE. of Moscow, has a cathedral (17th
century), a botanical garden, and manufactures of
paper; Pop. 47,701 (1883), in an area of 14,997 sq. miles, and its population of a million and a half are chiefly engaged in agriculture.

Penzance (Corn., 'holy headland'), a town of
Cornwall, the most westerly in England, at the
head of Mount's Bay, 10 miles ENE. of Land's
End, 15 miles S. of Plymouth, and 328 (by road
281) WSW. of London. Standing on a freely-
curved shore surrounded by rocky coves, it is
famous for its mild, equable climate, though the
annual rainfall is heavy (43 inches). Its
fine esplanade commands splendid land and sea views; and its chief buildings, excepted largely of granite, include a market-hall (1857) with a clock before it of Sir Humphry Davy (q.v.), an infirmary (1874), a post-office (1883), and public rooms (1867),
Italian Renaissance in style, and comprising a
guildhall, museum, library, &c. The harbour has
two piers (1772-1845) half a mile long, forming a
tidal basin of 21 acres; and docks have been added
since 1882. Penzance is a headquarters of the
mackerel and pilchard fisheries; market-gardening
is an important industry; and of recent years the
place has grown much in favour as a watering-
place. It was established in 1585, and sacked by
Fairfax in 1646, it was incorporated in 1648, and
from 1663 to 1838 was one of the five 'coining
towns.' Pop. (1881) 12,409; (1891) 12,448.
See works by Leth-Szyrma (1878) and Millett (1876-80).

Peonage, a system of agricultural servitude
common in Mexico (q.v.) and some other parts of
Spanish America. The peon in debt to his em-
ployer was by the Spanish colonial system bound
to labour for his employer until the debt was paid.
Peonage in New Mexico was abolished by act of
congress in 1867: it was also abolished in the
Argentina, Republic. 

Peony (Paeonia), a genus of plants of the
natural order Ranunculaceae, having large showy
flowers composed of five leafy herbaeous sepals
5 to 10 petals, numerous stamens, and 2 to 5 car-
pels, each with numerous round, black, shining
seeds. The leaves are compound, the leaflets
variously and irregularly divided. The fibres of
the root are often thin, to the touch. The species are large herbaeous perennials, or rarely
half-shrubby, natives of Europe, Asia, and the
north-west of America. None of them are truly
indigenous in Britain, although one (P. cornelliata
is undoubtedly naturalised on Steep Holme island in
the Severn. On account of the beauty of their
flowers, some of them are much cultivated in
gardens, particularly the Common Peony (P. 11

Pentecost
People's Palace, an institution at Mile End Road, intended as a centre for amusement and recreation, and of association as well, for the inhabitants of the East End of London. It comprises a large hall, technical schools, art-galleries, concert-rooms, a library, reading and recreation rooms, swimming-bath, gymnasium, &c. It is the revival and development of an idea of the Beaumont Philosophical Institute; but the idea was first amplified and made really popular in Mr Besant's novel, All Sorts and Conditions of Men (1882). The buildings were inaugurated by the Queen, May 14, 1887, and work was begun on 30 October. The Queen's Hall, which is 130 feet long by 75 feet wide, can seat 2500 people. Around the hall are the statues of twenty-two queens, and a large organ at the north end. The technical and art schools in 1890 were attended by 5000 pupils; they owe their foundation to the Drapers' Company of London, which has contributed in all about £50,000 to the People's Palace. Cheap concerts, at from 1d. to 5d. admission, have been well patronised, as also the picture exhibitions, gymnastics, swimming-bath, gymnasium, and dances. The evening classes attracted in 1898 an attendance of 900, for such subjects as elocution, physiology, drawing, machine construction, book-binding, and tailors' cutting.

See Besant's All Sorts and Conditions of Men; Sir E. Hay Currie's Working of the People's Palace; Nineteenth Century, February, 1890; Century, June 1890.

Peoria, capital of Peoria county, Illinois, on the west bank of the Illinois River, 294 miles by rail from Peoria Lake, 161 miles by railroad. It is an important railway centre—the Union Depot accommodates ten of the railways that meet here—and is connected by steamboat navigation with the Mississippi and by canal with Lake Michigan. It contains a Roman Catholic cathedral, a high school, a medical college, and three hospitals. The streets are wide, and there are ten parks, the largest, Jefferson, 35 acres. Mines of bituminous coal supply the city's numerous manufactories. These include especially the great distilleries, for which the plant is noted, and breweries, flour-mills, and manufactories of flour, oatmeal, and starch, glue, pottery, &c. In the lower city are large stockyards. Pops. (1880) 29,259; (1900) 56,100.

Peperino, a variety of tuff, met with in the Alban Hills near Rome. It is dirty greyish brown to white, earthy, and granular, and contains crystals of mica, leucite, augite, &c., with fragments of limestones, sandstone, and chalk. It is used for fireplaces, stoves, &c., and as a building material. It is also quarried in Fethard, Ireland, and in the Weald of Kent.

Pepin, or Pepian, sometimes called 'the Short,' king of the Franks, was the son of Charles Martel and the father of Charlemagne, and founder of the Frankish dynasty of the Carolingians (q.v.). Charles Martel shortly before he died divided his kingdom between his two sons, Carlemann and Pepin, Carlemann taking the German part, and Pepin the Neustrian or territories in northern France; still it they were only rulers (dukes) in the name of the Merovingian king. Carlemann, after five years of office or rule, was persuaded by the English monk Boniface to enter (747) the monastery of Monte Cassino; his duchy passed over to Pepin. St. Boniface in 751 crowned Pepin king of the Franks at Soissons, Childeric, the last of the ancient Merovingians, having been deposed and his very able substitute chosen king in his stead. Pepin rested his power in great part upon the bishops and monks; accordingly, when Pope Stephen III., who had been pressed by the Lombards (Lombards) under Aistulf, he came (754) to France to solicit help from the new king of the Franks, Pepin led an army into Italy, compelled Aistulf to become his vassal, gave to the pope the title of exarch (of Ravenna), and laid the foundation of the temporal sovereignty of the pope; himself he made 'patrician of the city of Rome—all this in 756. The church in his own dominions he placed under the supremacy of the pope. The rest of his life was spent in semi-crusading wars. Before going to Italy he had already attempted to convert the heathen Saxons at the sword's point; he went on with the 'holy' work in 757. Then he drove the Saemones back over the Pyrenees (758) and made (760-788) his holdings in Spain permanent. Though he never permanently conquered it. He died in 768, and his sons Carlemann and Charlemagne divided his territories between them. There were other rulers of this name amongst the Carolingians. PEPIN OF LANDEN (died 630), with the title of King in Ireland, was appointed mayor domus or viceroy of Austria under Lothair II.—PEPIN OF HERSTAL (died 714), his grandson, succeeded as mayor of the palace in Austria, to this added after 687 the similar vicerealties of Neustria and Aquitania, and called himself 'Duke and Prince of the Franks.' He was their real ruler during the reign of the puppet kings Theodoric, Ludwic III., Childebert III., Dagobert III., and fought successfully against the Frisians, the Alaman, and the
or C. Roxburghii yields the Long Pepper of commerce. They have woody climbing stems, solitary spikes with flowers and the fruits so close together on the spikes as in ripening to become a compact mass. The spikes are gathered when unripe, and dried in the sun. They are used in pickling and for culinary purposes, also in medicine for the same purposes as common pepper. They are generally reputed to be more pungent than common pepper.

C. Roxburghii is cultivated in eastern India, Ceylon, and Java. The root and thickest part of its stem are extensively used in India as a stimulant medicine.

Pepper acts on the skin as a rubefacient and vesicant, and is often used for this purpose in a powdered state, moistened with some kind of alcoholic spirit. It is also employed as a local stimulant in the relaxation of the uvula, and is applied in the form of an ointment to ringworm. Taken into the stomach in small quantities it is a pleasant stimulant, but in large doses it produces great pain and irritation. The quantity used, however, by the natives of hot climates much exceeds anything known among Europeans, and the effects are evidently beneficial rather than injurious.

The chief use of pepper is as a spice in vogue at present. Pepper was known to the ancients; Hippocrates employed it as a medicine, and Pliny expresses his surprise that it should have come into general use, considering its want of flavour. In the middle ages pepper was one of the most costly spices, and in the 13th century a few pounds of it were reckoned a princely present. The quantity now imported into Europe is immense. The average annual imports into the United Kingdom are about 29 million lb., of which about 7 million lb. are taken for consumption; the quantity imported into the United States is of the same order. Black pepper is considered the best kind, and the Tellicherry and Penang the finest varieties of the white.

The name pepper is popularly given to substances possessing a pungency resembling that of pepper, though produced by very different plants. Thus, Cayenne Pepper is the product of species of Capsicum (q.v.), of the natural order Solanaceae; Jamaica Pepper, or Pimento (q.v.), of species of Eugenia, of the natural order Myrtaceae; and Guinean Pepper, or Malaguetta Pepper, is Amomum, or West Indian Pepper Xylopia Althiopica, and Benin Pepper (Caraba Chin.)

Pepper. JOHN HENRY, chemist and mechanical inventor, was born in Westminster on 21 June 1821, and in 1848 was appointed analytical chemist at the Royal Polytechnic, and has written several handbooks of popular science. But he is best known as the improver and exhibitor of ’Pepper’s Ghost,’ in its earliest form the invention of Henry Dippels (q.v.), a device for associating on the same stage living persons and phantoms to act together. The phantom is produced by a large sheet of unslivered glass on the stage, practically invisible to the spectators, which reflects to them, along with a visible actor or actors, the appearance of another actor on an understage, who is himself invisible. Pepper travelled with this show in America and Australia, and became public analyst in Brisbane, Queensland.

Peppercorn Rent. A nominal rent of one peppercorn a year, to be paid on demand; an acknowledgment of tenancy when lands or houses are let virtually free of rent.

Peppermint. See MINT.

Pepper-pot, a celebrated West Indian dish, of which Cassareep (q.v.) is a principal ingredient; and along with it flesh or dried fish, vegetables,
chieflv the uripi pods of the ochre (a Hibiscus, q.v.), and chillies (see Capsicum).

Pepper-root (Dentaria diphylla), a perennial herb of the carrot family, is a native of North America, with pairs of tuberous leaves, and racemes of white flowers; the root of which has a pungent mustard-like taste, and is used as a condiment.

Pepsin has been already discussed (in the article Digestion), as one of the essential constituents of the gastric juice. Various modes of extracting it from the walls of the stomach of the calf, sheep, and pig have been proposed by different chemists. It has not been satisfactorily isolated, and its chemical constitution is unknown. 'At present the manifestation of peptic powers is our only test of the presence of pepsin' (M. Farquharson). This substance, either in powder or in solution, has been employed of late years to a considerable extent in medical practice, in cases of disorders of digestion due to deficient or imperfect secretion of gastric juice, and of convulsive and typhoid and other debilitating fevers. It is an ingredient in most of the digestive preparations now in the market.

Pepys, Samuel, the celebrated diarist, son of John and Margaret Pepys, was born on February 23, 1632-33. He was a member of a junior branch of an old and widely-spread family in the eastern counties. But there was little property in the possession of this branch, and Samuel's father for a time followed the business of a tailor in the city of London. It is not known whether the diarist was born at Brampton, a village near Huntingdon, or whether there was small property belonging to his father's family, or in the diarist's own way of thinking, ever, that he went to school at Huntingdon before entering St Paul's School, and that he remained at the latter until he was seventeen years of age. On March 5, 1650-51, he first put on his gown as a scholar at Magdalen College, Cambridge. On the 1st December 1655, very soon after leaving college, he was married to Elizabeth St Michel, a beautiful but portionless girl of fifteen. Sir Edward Montagu (afterwards Earl of Sandwich), whose mother was a Pepys, gave a helping hand to the imprudent contract. Pepys then lived in his house. But Samuel does not appear to have owed much to his father, it seems probable that Montagu acted as a patron at a still earlier period of his life. At all events his true start was entirely due to this patron, for whom Pepys always expressed the most unbounded attachment. Pepys' real life begins for us on the 1st January 1659-60, when the Diary was commenced. His appointment to the clerkship of the Acts of the Navy in 1660 was distinctly a job, for he knew nothing of the work of the navy when he undertook it, and even in a year or two the work of the navy assumed a character so utterly different from what he had expected that he was not at all prepared for it. Pepys, the diarist, never regretted the change. His main interest was his intelligence and industry were so great that he soon became master of the work of his office, and as Clerk of the Acts, and subsequently as Secretary to the Admiralty, he was one of the most distinguished officials in naval affairs ever possessed. At the Revolution his career was closed, but until the end of his life he was still looked upon as the Nestor of navy affairs, to be consulted upon matters of particular importance, and his name is still held in honour at the Admiralty. It is not, however, as an official that the fame of Pepys lives, but as the writer of a Diary which is unique in the literature of the world. This work has thrown the most unexpected light upon the history and manners of his day, while at the same time it presents a most remarkable psychological study. Never before had man written down his innermost feelings with so little disguise. Hence Pepys' character has suffered while his fame has spread. Passing thoughts which had but little real influence upon his actions were set down by him, and they have given a wrong impression of the man to numerous readers.

Pepys's life was prosperous, for he made money and held high offices. He was twice Master of the Trinity House, first in 1676 and a second time in 1685, Master of the Clothworkers Company in 1677, and President of the Board of Trade in 1693. But he was not without his troubles. At the period of the supposed Popish Plot in 1679 he was committed to the Tower, and in 1690 he was placed in Gatehouse at Westminster for a few days; and at his death in 1703 he was indebted to him to the extent of £28,000, a sum which was never paid. Early in life Pepys was successfully cut for the stone, and for many years he enjoyed good health, but before his death, on the 20th May 1703, the wound broke out afresh. The Diary was discontinued on 29th May 1669, and we must ever regret that it was not continued to a later period. The shorthand MS. was deciphered by the Rev. J. Smith and first published in 1825 under the editorship of Lord Braybrooke. Although much original matter has been added to various religious, political, and social periodicals of that time, in The London Journal (Bright 1875), the Diary had never been printed in its entirety up to 1891, when a new edition of the whole was in preparation. Besides the Diary Pepys wrote nothing of importance but his Memoirs relating to the State of the Royal Navy, published in 1690. Pepys was essentially a collector, and he never saw a curious or uncommon object without wishing to possess it. His library, bequeathed to Magdalen College, Cambridge, still remains in the exact condition in which he left it. In the room containing that library and among his books and papers we see the beginnings of that method, diligence, and general intelligence which is exhibited in the Diary, and which, united with the power of carrying out his views, helped to consolidate the British navy.

See Memoirs of Samuel Pepys, Esq., Comprising his Diary from 1659 to 1669, edited by Lord Braybrooke (2 vols. 1825); Diary and Correspondence, by Rev. Mynors Bright (6 vols. 1875); Life, Journal, and Correspondence of Samuel Pepys, by Rev. John Smith (2 vols. 1841); and particularly in that of the Rev. M. Bright (1875), the Diary had never been printed in its entirety up to 1891, when a new edition of the whole was in preparation. See Memoirs of Samuel Pepys, Esq., Comprising his Diary from 1659 to 1669, edited by Lord Braybrooke (2 vols. 1825); Diary and Correspondence, by Rev. Mynors Bright (6 vols. 1875); Life, Journal, and Correspondence of Samuel Pepys, by Rev. John Smith (2 vols. 1841); and particularly in that of the Rev. M. Bright (1875), the Diary had never been printed in its entirety up to 1891, when a new edition of the whole was in preparation. See Memoirs of Samuel Pepys, Esq., Comprising his Diary from 1659 to 1669, edited by Lord Braybrooke (2 vols. 1825); Diary and Correspondence, by Rev. Mynors Bright (6 vols. 1875); Life, Journal, and Correspondence of Samuel Pepys, by Rev. John Smith (2 vols. 1841); and particularly in that of the Rev. M. Bright (1875), the Diary had never been printed in its entirety up to 1891, when a new edition of the whole was in preparation.

Pequot, or Pequots, a tribe of American Indians, a branch of the Mohicans, were warlike and powerful in the country round the Thames River when Connecticut was first settled, and made treaties with the Dutch and English. Hostilities, however, broke out in 1637, and the tribe was cut to pieces and scattered; yet a few descendants may be found at Green Bay, Wisconsin.

Pera, a suburb of Constantinople (q.v.).

Peraea (Gr. 'the country beyond'), a term applied to many districts beyond a river or sea; most frequently to great parts of Palestine (q.v.) beyond the Jordan.

Perak, a Malay state on the west side of the peninsula of Malacca, under the protection of Britain since 1874. Estimated area, 7950 sq. m. The interior ranges up to 8000 feet. The soil is fertile, and for the most part covered with luxuriant vegetation. Elephants, leopards, tigers, monkeys, and deer swarm in the forests of the interior. The soil produces rice, sugar, tobacco, coffee, tea, vanilla, and spices. But the principal production of the state is tin; the mines, worked chiefly by Chinese, yielded 2960 tons in 1875 and 25,856 tons in 1890. Lead also exists in great quantity. Pop.,
most Malay and Chinese, increased from 55,880 in 1879 to 214,524 in 1881. The island of Kwada was also named Kito, the principal

the British have made many miles of good roads since they began to govern the country. The murder of J. W. Birch, the first British resident, in 1875 necessitated a punitive military expedition in 1876. The state is now in a highly prosperous condition, exporting to the annual value of $15,000,000, and importing to $10,000,000. See books by McNair (1877) and Swettenham (1894).

Perambulation. See Bounds (Bratislava).

Perameles. See Handicoot.

Perception, in philosophical usage, may mean internal perception, the appreciation of objects whose modification is consciousness; but it usually refers to external perception, the recognition of an external object by means of the senses—something more than sensation, and including an element of judgment or the comparing power.

Two great disputes concern themselves with perception, both raised to prominence by Berkeley. The first is the origin of our judgments of the distances and real magnitudes of visible bodies; Berkeley maintaining, in opposition to the common opinion on this subject, that these were learned by experience, or known by the senses, were not in vision (see Vision). The second question relates to the grounds we have for asserting the existence of an external and material world. See Berkeley, Kant, Reid; also Psychology, Philosophy.

Percival, Spencer, English minister, was the second son of the second Earl of Egmont, and was born in London, November 1, 1762. He was educated at Harrow and Trinity College, Cambridge, and was called to the bar at Lincoln's Inn in 1786. He soon obtained a reputation as a diligent lawyer, and in 1796 he entered parliament for Northumberland, and became a strong supporter of Pitt. In the Addington administration he was made Solicitor-general in 1801 and Attorney-general in 1802, and in the Portland administration of 1807 he became Chancellor of the Exchequer, and was even then the real head of the government, though more truly, by George IIIi, for his steadfast opposition to the Catholic claims. On the death of the Duke of Portland in 1809 Percival became premier also, and retained office till his tragic death, 11th May 1812, when he was shot dead entering the lobby of the House of Commons. Great was the consternation caused by a Liver-

pool broker named Bellingham, whose losses had turned his head. Percival's death was rather a private than a public calamity. He was a man of spotless integrity in his public and private character, but, though an effective parliamentary debater, his abilities were only moderate and his views were narrow.

Percival, James Gates, an American poet, was born at Kensington, Connecticut, 15th September 1763, graduated at Yale in 1815, at the head of his class, and afterwards studied botany and medicine. But his heart was not in herbs and classifications; and although he professed—or rather advertised his willingness to practise—both in Kensington and in Charleston, S.C., very few professional calls dragged him from his favourite studies. His poems Promethus and Oio appeared at Charleston in 1822. Two years later he filled for a few months the chair of Chemistry at West Point; but he found the duties heavy and irksome, and took himself to Boston, and then to New Haven. There the third part of Oio was published (1827). Percival afterwards divided his attention between his verses and geology, and as he grew older he gave more and more of his time to the new love, the visible results being Reports on the Geology of Connecticut (1842) and of Wisconsin (1856). These are valuable but very dry, and in delusions contrast to his poems, which flow freely and with volume, and on whose fluent, half-crescendo, and more lines their author's learning is borne as easily as trees on a river in flood. His Dream of a Day appeared in 1843, and occasional lyrics for a long time after. He was appointed geologist of Wisconsin in 1854, and died there at Hazel Green, on 20 May 1856. His collected works were published in 1859, his Life and Letters, by J. H. Ward, in 1866.

Perch (Perca fluviatilis), seven indistinct dark bands on the back. In length it measures about 18 inches, and its height is about a third of this. It sometimes weighs from three to five pounds, and a prize of nine pounds has been recorded. Among its characteristics may be noted the small villiform backward-turned pectorals, their presence on the palatine, and visceral, their absence from the tongue, the two dorsal fins, of which the first has thirteen or fourteen spines, and the small scales on the body. The perch loves still waters, and thrives well in ponds, at the cost, however, of smaller fishes. It also feeds on insects, worms, &c. It can endure removal from the water for a considerable time. The eggs are laid in spring, and are attached in long viscid strings to water-weeds. The number of eggs in one spawn may exceed a million. As an edible fish the perch has a good reputation, eating best with lemon-juice and catsup-pepper, but the American variety is less esteemed. Of species distinct from P. fluviatilis little is known.—The so-called Climbing Perch (q.v.) is separately treated.

Perch, a measure of length. See Rod.

Percival.多数为马来人和中国人，从1879年到1881年，人数增加到55,880人。该岛名为Kwada，又名Kito，是主要的居民地。自他们开始统治该国以来，情况发生了很大的变化。1875年发生了一起谋杀案，即J. W. Birch，他是第一位驻该岛的英国居民，需要进行一次惩罚性的军事远征。该州目前处于高度繁荣状态，每年出口价值为15,000,000美元，进口价值为10,000,000美元。见书McNair (1877)和Swettenham (1894)。

Perambulation。意为界限(布拉蒂亚)。

Perameles。见Handicoot。

Perception，哲学上使用时，意指对外部感知，对物体的欣赏，而不是仅仅通过感觉，还包含判断或比较的能力。两个主要的争议涉及感知，由伯克莱提出，两人都对存在外部世界提出质疑。见Berkeley，Kant，Reid；亦见心理学，哲学。

Percival，Spencer，英国政治家，是第二代伊蒙顿男爵的次子，1762年11月1日出生在伦敦。伯克莱大学接受过教育，并在林肯厅律师学院学习，1786年成为律师。随后，他在1796年进入下议院，担任诺森伯兰郡议员，并成为皮特的坚定支持者。在安登顿政府时期，他担任索德里尼和内阁的律师，1801年和1802年担任大律师，1807年担任财相，成为政府的实际领导人。在1809年，道尔顿伯爵去世后，他成为政府首脑，但在1812年5月11日，他被枪杀身亡。珀塞尔的死亡是私人灾难，他是一位德高望重的作家和私人品格，但尽管他是一位有效的辩论者，他的能力是有限的，观点是有限的。

Percival，James Gates，美国诗人，1763年9月15日出生于康涅狄格州肯辛顿，1815年毕业于耶鲁大学，以他班的头名毕业，并随后学习了植物学和医学。但他的心不在草药和分类学上，尽管他曾经承诺——或者更确切地说，他宣称他的愿意——在肯辛顿和查尔斯顿，S.C.，很少有专业性的来访者能让他从他最喜欢的学科中挣脱出来。他的诗《普罗米修斯》和《奥伊》出现在1822年查尔斯顿。两年后，他为西点军校的化学教授工作了一段时间；但他发现这项工作很沉重，令人厌倦，于是他将自己转向波士顿，并随后到了新罕布什尔。他在那里完成了《奥伊》的第三部分。1827年，佩尔塞尔的注意力分散在诗歌和地质学之间，随着年龄的增长，他将越来越多的时间投入到新爱好上，即地质学，结果是，他在康涅狄格和威斯康星州撰写了报告，这些报告是很有价值的，但也很枯燥，与他的诗歌形成了对比，后者自由流畅，音量丰富，与他那流利的，半声乐的，和更多的线，作者的学习被天生的，就像树上一样流过，他的《梦与日》出现在1843年，并发表了一些偶然的歌词。在他的诗歌和地质学之间，随着年龄的增长，他将越来越多的时间投入到新爱好上，即地质学，结果是，他在康涅狄格和威斯康星州撰写了报告，这些报告是很有价值的，但也很枯燥，与他的诗歌形成了对比，后者自由流畅，音量丰富，与他那流利的，半声乐的，和更多的线，作者的学习被天生的，就像树上一样流过，他的《梦与日》出现在1843年，并发表了一些偶然的歌词。在他的诗歌和地质学之间。
Percussion: Medicine, is the method of eliciting sounds by tapping gently but distinctly the surface of the body; its object being to determine by the nature of the sound the comparative density of the subjacent parts. This means of diagnosis was first employed by Alenbrugger in the middle of the 18th century, and it was afterwards adopted by the French and German physicians, but its value was not fully appreciated till Laennec made the diseases of the chest his peculiar study; and since his time its application and various uses have been extended by the labours of Pierry, Hugues Bennett, and other physicians.

Percussion is the discussion of the diagnosis of the lungs, heart, and abdominal organs. It may be direct (or, as some writers term it, immediate), or it may be indirect. In the former case, the part to be examined is struck with the ends of the first three fingers set close together. When the patient, or with a small hammer tipped with india-rubber; while in the latter, which is now almost universally adopted, a flat body is placed upon the chest, or other part to be examined, and is then struck by the fingers or hammer, the intensity of the percussion is termed Plicimeter (from the Gr. peluitis, 'a blow,' and metron, 'a measure'). The instrument usually sold as a plicimeter is a flat oval piece of ivory, but the left index or middle finger of the physician, with its flat surface fitted accurately to the part to be examined, is sufficiently well. The sense of one or both strokes on the plicimeter—whether the stroke be made with the fingers or the hammer—must vary according as it is desired to elicit the sound from a superficial or a deep-seated part. The surface to be percussed should be exposed, or, at most, only covered by clothing. The admeasurement of the admeasurement of the depth of the cavity filled with air—as the stomach or intestines—a hollow, drum-like, or (as it is usually termed by medical writers) a tympanitic sound is produced. When the patient, or with a small hammer tipped with india-rubber, is so placed, and the surface of the chest is struck below where there is a considerable depth of healthy lung-tissue, consisting of small cells filled with air, a clear sound, less loud and hollow than the tympanitic sound, and termed the pulmonary percussion depending only on the vibrations of air in the lung-cells, and whereby the vibrations of the walls of the chest, is evoked. When the subjacent substance is solid (as the heart, liver, or spleen) or fluid (as when there is effusion into a closed sac) the sound is dull in proportion to the density and want of elasticity of the part struck. Important information is also gained by attending to the varying degree of resistance experienced by the fingers during percussion over different parts of the surface. The first thing that must be acquired in order to make percussion useful in the diagnosis of disease is an accurate knowledge of the sounds elicited from the different parts in their normal condition. When, for example, the healthy pulmonary percussion note is known, increased resonance of the walls of the chest will indicate a dilatation of the air-cells (or the pulmonary emphysema), an aggregate of dullness will afford evidence of such morbid changes as the effusion of fluid into the pleura (Hydrothorax), or inflammatory solidification of the lung-tissue (the Hydatid of Pneumonia), or malacic or dry emphysema. Percussion in relation to diagnosis is further shown in the articles PERICARDIUM and PLEURISY. Diagnosis by Auscultation (q.v.), directly and by means of the Stethoscope (q.v.), is often used in connection with percussion.

Percussion Caps are small copper cylinders, closed at one end, for conveniently holding the detonating powder which is exploded by the act of percussion. See FULMINATES; also FIREARMS, Vol. IV, p. 639.

Percussion, Centre of. See Centre of Percussion.

Percy, a noble northern family, famous in the history of England for five hundred years. Its founder, William de Percy, was the Conqueror to England, and was rewarded with lands in Hampshire, Lincolnshire, and Yorkshire—among the last being Topoiffe and Spofforth, long the chief seats of the house. The male descendants became extinct in the direct line, and the representation of the house devolved upon his daughter Agnes, who married Josceline of Louvain, brother-in-law of King Henry I., on the condition that he assumed the name of Percy. Their youngest son, Richard de Percy, then head of the family, was executed in the chieftains who extorted Magna Carta from King John, and the ninth feudal lord, Henry de Percy, gave much aid to Edward I. in the subjugation of Scotland, and was made governor of Galloway. The latter was driven out of Turnberry Castle by Robert Bruce, and was rewarded by Edward II. with the empty honour of Bruce's forfeited earldom of Carrick, and the governorship of the castles of Bamborough and Scarborough. In 1309 he obtained by purchase from Bishop Antony Bek the barony of Alnwick, the chief seat of the family ever since. His son, Earl Richard, and his son-in-law, Percy, King David II. of Scotland at the battle of Neville's Cross (1346); his grandson fought at Crécy; his great-grandson, the fourth Lord Percy of Alnwick, was marshal of England at the coronation of Richard II. On the death of John Earl of Northumberland, Henry, eldest son of the last, was the famous Hotspur whom the dead Douglas defeated at Otterburn (1388), and who himself fell at Shrewsbury (1403) fighting against King Henry IV. His brother, Thomas Percy, Earl of Warkney, was executed immediately after the battle. Their father, who had turned against Richard II., and helped Henry of Lancaster to the throne, was dissatisfied with Henry's gratitude, and with his son plotted the insurrection which ended in Shrewsbury fight. Later he was rewarded, but fell at Bramham Moor (1408), when his honours were forfeited on attaint, but restored in 1414 to his grandson Henry, the second earl, from which day the Lancasterian loyalty of the family never wavered. Henry became High Constable of England, and fell in the first battle of St. Albans (1455). His son Henry, the third earl, fell at Towton (1461), and it was his brother, Sir Ralph Percy, who comforted himself as he lay bleeding to death on Hedgehog Moor (1464), that he had 'saved the bird in his bosom.' The title and estates were now given to Lord Montagu, a brother of Warwick, the king-maker, but in 1469 Henry, the son of the third earl, subscribed an oath of allegiance to Edward IV., and was restored. He was murdered at his Yorkshire house of Cockledge, in 1489, in an outbreak of popular fury against an extortionate subsidy of Henry VII. The sixth earl, Henry-Algermon, in youth had been the lover of Anne Boleyn, and was forced against his will to marry a daughter of the Earl of Shrews-

bury. He died childless in 1507, and, as his brother, Sir Thomas Percy had been attainted and executed for his share in the Pilgrimage of Grace, the title and honours were forfeited, and the title of Duke of Northumberland was conferred by Edward VI. upon John Dudley, Earl of Warwick, who in turn was attained and executed under Mary in 1558. That queen in 1557 granted the earldom to Thomas
Percy, son of the attainted Sir Thomas Percy. A devoted Catholic, he took part in the Rieging of the North, and was beheaded at York in 1572. His brother Henry succeeded in the original family at Alnwick, and invested in Tengemouth's conspiracy in favour of Mary Stuart, and was committed to the Tower, where he was found dead in bed, with a pistol beside him, whether through suicide or murder, 21st June 1585. His son, the ninth earl, was imprisoned by Elizabeth, but escaped, and found £30,000 on a baseless suspicion of being privy to the Gunpowder Plot. He was followed by his son, the tenth earl, who fought on the parliamentary side in the Civil War, and was succeeded by his son Josceline, the eleventh earl, with whose death in 1670 the male line of the family became extinct. Charles II. created in 1674 his third bastard by the Duchess of Cleveland, Earl, and afterwards Duke, of Northumberland, but the titles expired on his dying childless in 1716. The eleventh earl's only surviving child and heir, in her own right Baroness Percy, married Charles Seymour, Duke of Somerset, and became the mother of Algernon, Duke of Somerset, who was created in 1749 Baron Warkworth and Earl of Northumberland, with remainder to his son-in-law, Sir Hugh Southwell, fourthly, of Worksop. Sir Hugh Southwell succeeded to the earldom in 1750, assuming the surname and arms of Percy, and was created in 1766 Earl Percy and Duke of Northumberland. The sixth duke succeeded in 1867.

Percy, Thomas, editor of the famous Reliques of Ancient English Poetry, was born a grocer's son at Bridgnorth in Shropshire, April 13, 1729. He was educated at the grammar-school there; in 1746 entered Exeter College, Oxford, and in 1753 was presented by his college to the sequestered vicarage of Easton Maudit, Northamptonshire, where he lived for twenty-five years. In 1756 he married happily, and three years after received also the adjacent rectory of Wilby. His leisure soon yielded fruit in his An Essay towards a New Dramatick Language, a Chinese novel translated from the Portuguese, and Miscellaneous Pieces relating to the Chinese (2 vols. 1762), as well as anonymously in Five Pieces of Chinese Poetry translated from the Mandarin (1763), prompted by Thomas Howard, afterwards Viscount Howard, in his Translation of the Song of Solomon from the Hebrew (1764). In the summer of 1764 Dr Johnson paid him a long visit at Easton Maudit. In later days they sometimes quarrelled, but continued to retain a high regard for each other. 'A man out of whose company I never go without having learned something'—so Johnson described him to Boswell. 'I am sure that he vexes me sometimes, but I am afraid it is by making me feel my own ignorance.' In the February of the following year (1766) Percy published in the Reliques of Ancient English Poetry (4th ed. 1770, an enlarged edition by H. Wheatley, 3 vols. 1886). He had long been engaged in collecting old ballads from every quarter, and a large folio MS. of ballads had fallen accidently into his hands, having been found 'lying dry on the floor under a Rhenish in the Parlour' of his friend Humphrey Pitt of Shifnal, in Shropshire, 'being used by the maids to light the fire.' This he claimed as the original of his work, but of the 176 pieces in the first edition actually only 42 were taken from the folio MS.; while almost all those actually from it were so touched up and tricked out in false ornament and conventional 18th-century poetical diction as often to bear but little likeness to their originals. For example, the 39 lines of the 'Child of Eli' have been put out to 200 in Percy's version, nor do even all the 36 originals themselves appear. Again, the 'Heir of Lin' has swollen from 125 lines to 216, and these, moreover, produced to death. The antient Rieging, in his Ode to the Centurp. Micke these" prefixed to his Ancient Songs from Henry III. to the Revolution (1790), attacked Percy with characteristic acrmony, denied the very existence of the folio MS., and denounced the work as an impudent forgery, and that the worse became the clergyman. Percy exhibited the MS. in Pall Mall, and had his portrait painted by Sir Joshua Reynolds holding it in his hand. For over a hundred years it lay hid in Eaton Hall, jealously guarded from almost all eyes, until at length Mr Furnivall, instigated by Professor Child, succeeded in getting it printed in vols. 1867-85; (those deservedly marked by the biographer "useless and humorous' being printed separately), with Introductions by Professor Hales and himself. The MS. was 134 inches long by 53 wide and about 2 inches thick, and was written in a Caroline hand.

The publication of Percy's Reliques was first suggested to him by Smollett. The work was dedicated to the Countess of Northumberland, and the author was soon rewarded by being made chaplain to her husband, the first duke of the present creation, while he also succeeded in persuading her to propose marriage to the nobler born Percy. In 1769 he became chaplain to George III., and next year he took his degree of D.D. at Cambridge, and published his translation of the Northern Antiquities of the Swiss historian Paul Henri Mallet (1759-1807). About 1771 his wife was appointed nurse to the Prince Edward, afterwards father of Queen Victoria; it was to her, before their marriage, that Percy addressed the famous ballad, 'O Nancy wilt thou go with me?' first printed in 1758, and happily set to music by an Irishman, Thomas Carter (c. 1733-1864). In 1771 Percy wrote a novel prefixed to the Prince Edward, afterwards father of Queen Victoria; it was to her, before their marriage, that Percy addressed the famous ballad, 'O Nancy wilt thou go with me?' first printed in 1758, and happily set to music by an Irishman, Thomas Carter (c. 1733-1864). In 1771 Percy wrote a novel prefixed to the book. During the reign of George III. Percy was appointed to the deanship of Carlisle, in 1782 to be Bishop of Dromore, with £2000 a year. His only son died in 1783; his wife in 1806; he himself, after a few years of blindness, 30th September 1811—the only survivor of the original chieftains of his family's famous Literary Club. He left two daughters, and was buried in the transept which he himself had added to Dromore Cathedral.

For the literary influence of the Reliques, see the article HALLAX. A good Life by the Rev. J. Pickford is prefixed to vol. i. of the edition of Furnivall and Blackmore. Many of his letters are given in vol. viii. of J. B. Nichols's Illustrations of the Literary History of the 18th Century. His name was assumed by the Percy Society (94 issues, 1840-52).

Percy Anecdotes, a collection of extraordinary popularities, published in monthly parts (1829-33) by 'Shalto and Reuben Percy, Brothers of the Benedicite Monastery of Mount Benger.' Their real names were Thomas Byerley (died 1825), first editor of the Mirror; and Joseph Clinton Robertson (died 1832), projector and editor of the Mechanics' Magazine; the work owed its name to the Percy Coffee-house in Rathbone Place, their usual place of meeting during its progress. An edition was prepared by John Timbs (1852).

Peregrine Falcon. See FALCON.

Pereira, Jonathan, pharmacologist, was born at Shoreditch, London, 22nd May 1804, and was successively lecturer on chemistry and physician to the London Hospital (1841). Elected a Fellow of the College of Physicians in 1845, he acted as examiner in Matier Maligia and Pharmacy from the establishment of the London College until his death, 20th January 1853. His books were Elements of Matier Medicin (1839-40), and treatises on Diet and on Polariised Light (1843). See Memoir (1853).
PEREFONIST.

PEREFONISTS. 45

Pereslav, a town of Russia, 96 miles NE. of Moscow by rail. It has a 12th-century cathedral, cotton-manufactures, and lake-fisheries. Pop. 7466.

Perez, Antonio, minister of Philip II. of Spain, was born in Aragon in 1539. His reputed father was an ecclesiastic who was secretary to Charles V. ministered Philip II., and was himself appointed to this office when only twenty-five years of age, and acquired the entire confidence of the king. Don John of Austria having set his confidant, Juan de Escovedo, to Spain, to solicit aid against the party of Orange, and Escovedo having rendered himself an object of suspicion to the king as an adherent of Don John's ambitious schemes, Philip resolved to put him out of the way by murder, and entrusted Perez with the accomplishment of this design, which Perez accomplished accordingly, 31st March 1578. The family of Escovedo, with that of their principal enemies joined against him. The king at first sought to shield him; but in July 1581 he was arrested, and by torture forced to confess. He succeeded, however, in making his escape to Aragon, where he put himself under protection of its kings, which secured a trial in open court. The king, charging him with heresy, now applied for aid in May 1591 to the Inquisition, and the Aragonese court delivered him up to its agents; but the people rose in tumult and liberated him. This happened repeatedly; and at last, in September 1591, Philip II. entered Aragon with an army powerful enough to subdue all opposition, and abolished the old constitutional privileges of the country. Perez, however, made his escape, was condemned in Spain as a heretic, but was treated with great kindness by Philip II., who himself the was the intimate of Bacon and the Earl of Essex. He spent the later years of his life in Paris, and died there, 3d November 1611, in great poverty. Perez wrote Relaciones (1598), which states recent writers have regarded as lying fabrications.

See Mignet's monograph (5th ed. 1881); Morel-Fatio, L'Espagne au XVI., et au XVII. Siecle (1878); also Froude in The Spanish Story of the Armada (1892); and works cited at Philip II.

Perfectibility, or PERFECTIONISM, the doctrine that man in a state of grace may attain to perfection in this life. Catholics hold that no one, not even the most holy, can avoid sin altogether except by a special privilege of God, as in the case of the Blessed Virgin; the justified do not, however, commit mortal, but venial sins (see S.N.). In various points Francisians, Jesuits, and Molinists approach to a doctrine of perfection denied by Dominicans and Jansenists. Among Protestants, Wesleyan Methodists believe in the attainability of a Christian perfection attainable in this life. It is not a perfection of justification, but a perfection of sanctification; which John Wesley, in a sermon on Christian Perfection, from the text Heb. vi. 1, Let us go on to perfection, earnestly contends for as attainable a state of life by believers. It is founded chiefly on the commandments and promises of Scripture concerning sanctification; guarding his doctrine, however, by saying that it is neither an angelic nor an Adamic perfection, and does not exclude ignorance and error of judgment, with consequent wrong affections, such as 'needless fear or ill-grounded hope, unreasonable love, or unreasonable aversion.' He admits, also, that even in this sense it is a rare attainment. The Friends profess that the justified may be 'free from actual sinning and transgression of the law of God, and in that respect perfect; but not so both in respect of growth; and there remaineth a possibility of sinning where the mind doth not most diligently and watchfully attend unto the Lord.' Other schools also hold similar views; but most Protestants repudiate the doctrine of Perfectibility. The general belief of Protestant Christians is that those who have professed a belief in their own perfectibility were merely more self-complacent and less sensible of their own corruptions than is usual, and that the commands and promises concerning sanctification are all in explanation consistent with remaining corruption in believers, and a need of further sanctification, or a continued going on unto perfection whilst this life endures.

Perfection, Counsels of. See Supererogation.

Perfectionists, also called Bible Communists and FREE-LOVERS, a small American sect, founded by John Humphrey Noyes, who was born at Brattleboro, Vermont, on 15th July 1811, graduated at Dartmouth in 1830, then studied law, and afterwards theology at Andover and Yale. While a theological student, he experienced a second conversion, discovered that the prevailing theology was wholly wrong, and lost his license to preach. He held that the gospel if accepted secures freedom from sin; that God has a dual body (male and female); that the author of evil is uncreated, but not God; and that communion with Christ not merely saves from sinning, but from disease and death. He now founded a 'Perfectionist' church at Putney, Vermont. He and his converts, men and women, with their children, put their property into a common stock; they gave up the use of prayer, all religious service, and the observance of the Sabbath; those who were married renounced their marriage ties, and a 'complex marriage' was established between all the males and all the females of the 'Family.' Having dispensed with law, he set up public opinion as a controlling power in its stead; and free criticism of one another by the members of the society became an important feature of his system. In 1849, after not a few difficulties, the community removed to a new home in the sequestered district of Oneida, in the state of New York, and soon numbered some 300 members, living in strict order and with much outward comfort on thoroughly communalistic principles—the community of women and of children being an
outstanding feature carefully regulated by the 'mutual criticism' of the family. In 1880, however, the presence of outside opinion forced the family to modify their views. The original perfect family relationship was introduced; communism of property gave way to limited liability joint-stock, each member having a separate share represented by so much stock in the Oenida Community, Limited. Various co-operative institutions were established. The headquarters are at Kenwood, New York, and works have been started also at Niagara Falls, Ontario, Noyes, who assisted in establishing the new constitution, died at Niagara Falls, 13th April 1886.

Perfumery. Perfumes are of two distinct classes—those derived from plants and those which are of animal origin.

Vegetable Perfumes.—The most ancient of the so-called primary odoriferous bodies are the so-called gunn-resins which exude naturally from the angiosperms, as oozes; marriage accidental or purposely inflicted to increase the yield. The most important are benzoin, myrrh, epononox, tola, Peru, and storax. Gum-resins form the chief ingredients in 'Incense' (q.v.) and Pastilles (q.v.).

A second group is that large class of perfumes which are produced by distillation, and are most of them fluid bodies, and are termed Volatile Oils, Essential Oils, or Ottos—formerly Quintessences (see Oils). As soon as the Greeks and the Romans learned the use of the still, which was an invention im- parted to them from Egypt, they quickly adapted it to the distillation of the odorous principles from the numerous fragrant plants indigenous to Greece and Italy. Long before that time, however, fragrant waters were in use in Arabia. Odour-bearing plants contain the fragrant principle in minute glands or sense-cells. These are found sometimes in the rind of the fruit, as the lemon and orange; in others it is in the leaves, as sage, mint, and thyme; in wood, as rosewood and sandalwood; in the bark, as cassia and cinnamon; in seeds, as caraway and nutmeg; in yet others in the petals, as in rose, lavender, or lilac; in flowers, as in rose; in wood, as in orris, a solid resembling cocoa-butter, and is contained in what is really the rhizome of Iris florentina, though technically called orris-root. These glands or bags of fragrance may be plainly seen in a thin-cut stratum of orange peel; so also in a bay leaf, if it be held up to the sunlight, all the oil-cells may be seen like specks. All the fragrance-bearing substances yield by distillation an essential oil peculiar to each; thus is procured oil of patchouli from the leaves of the patchouli plant, Pogostemon patchouli, a native of Burma; oil of caraway, from the caraway-seed; oil of geranium, from the oil of the Pelargonium roseum; oil of lemon, from lemon-peel, Citrus limonum; and a hundred of others of infinite variety.

For the various essential oils or ottos are very slightly soluble in water, so that no distillation the water comes over is always fragrant. Thus, elder-water, rose-water, orange-water, dill-water are, as it were, the residue of the distillation for obtaining the several ottos. The prominent (q.v.) is very simple: the fragrant part of the plant is placed in the still and covered with water, and when the water is made to boil the ottos rise along with the steam, are condensed with it in the pipe, and remain floating on the water, from which they are easily separated by decanting. In this way 100 lb. of orange, lemon, or bergamot fruit peel will yield about 10 oz. of the fragrant oil; 100 lb. of cedar-wood will give about 15 oz. of cedar-wood ottos; the ottos from nutmeg will yield 60 to 70 oz. of oil of nutmeg; 100 lb. of geranium leaves will yield 2 oz. of oil.

Every fragrant substance varies in yield of essential oil. The variety of essential oils is endless; but there is a certain relationship among odours as among flowers. The lemons, like nutmegs are the most numerous, such as verbena, lemon, bergamot, orange, citron, citronella; then the almond-like odours, such as heliotrope, vanilla, violet; then spice odours, cloves, cinnamon, cassia. The whole may be classified into twelve well-defined groups. All these ottos are very soluble in alcohol, in fat, butter, and fixed oils. They also mix with soap, snuff, starch, sugar, chalk, and other bodies, to which they impart their fragrance.

The principal consumption of the cheaper sorts of fragrant ottos is for scenting Soaps (q.v.), most of which are perfumed with the Alpes Martial state with the several ottos or mixtures of them. The best qualities of soaps, however, are scented cold by grinding or squeezing the previously dried soap between granite rollers after having been mixed with the perfumes. With perhaps the exception of the 'secrets' used for snuffs and tobacco can scarcely be termed perfumes. There is a large consumption of fragrant essential oils in the manufacture of toilet powders; under the various names of rose powder, violet powder, &c.; a mixture of starch and ottos, differently scented, is used for the same purpose—drying the skin of infants after the bath. Precipitated chalk and powdered cuttle-fish bone, being perfumed with otto of roses, powdered myrrh, and camphor, become ' Dentifrices. The ottos of peppermint, lavender, rose, and others are extensively used in flavouring sweetsmeats and lozenges.

It is found that some flowers either do not yield an essential oil by distillation or yield it in quantities too small to be commercially available. The perfume from these is collected by the process called 'absorption.' The flowers of many of our marin- times follow this method on a very large scale with the following flowers: rose, orange, anemon, violet, jasmine, tuberose, and jonquil. In the valley of the Var there are acres of flowers, the blossoms of which are gathered by women and children, and dried in little Tagam beans fishermen's baskets, hanging over the shoulders. They are then carried to the laboratory of flowers and weighed. In the laboratory great quantities of grease, lard, and beef-suet have been collected, melted, washed, and clarified. In each laboratory there are several thousand châlzes or châlères ('sashes'), upon which the grease to be scented is spread, and upon this grease the blossoms are sprinkled or laid. The châlze en verre is, in fact, a frame with a glass in it as near as possible like a window-sash, only that the frame is two inches thicker, so that while the leaves of the flowers are kept together, there is a space of four inches between every two glasses, thus allowing space for blossoms. The flower blossoms are changed every day, or every other day. The same grease, however, remains in the châlze so long as the particular plant being used yields blossoms. Each time that a flower is put on, the grease is 'worked'—i.e. stirred with a knife—so as to offer a fresh surface of grease to absorb odour. The grease being enfleurée or 'enflowered' in this way for three weeks or more—i.e. along with the plants produce blossoms, the fat is finally boiled of aromatic matter, i.e. is at last scraped off the châlze, melted, strained, and poured into tin canisters, and is now fit for exportation. Fat or oil is perfumed with these same flowers by the process of maceration—i.e.
infusion of the flowers in oil or melted fat. For this end purified fat is melted in a bain marie, or warm water bath, and the fresh blossoms are immersed for the required time. When they are procured, the spent blossoms are strained away, and new flowers added repeatedly, so long as they can be procured. Oil does not require to be warmed, but improved results are obtained when it is slightly heated.

Some perfumers produce best perfumed grease by enfleurage, but rose, orange, and acacia give more satisfactory products by maceration; while violet and jonquil grease is best obtained by the joint processes—enfleurage followed by maceration. In the place of glass the space is filled with a wire-net on which is laid a mohlera, or other cotton fabric—moleskin, soaked with oil; on this the flowers are laid, just as with solid grease. In due time—that is, after repeated changing of the flowers—the oil becomes fragrant, and it is then pressed out of the molletters, as far as odour is concerned. In this case the grease is made as solid as is consistent with the required purposes. In order now to obtain the perfume of these flowers in the form used for scenting handkerchiefs, we have only to infuse the scented fat or oil, made by any of the above methods, in strong alcohol.

Some perfumers think that it is not too thick a fluid that it has to be chopped up as fine as suet is chopped, put into the spirit, and left to infuse for about a month. In the case of scented oil it has to be repeatedly agitated with the spirit. The result is that the spirit extracts all the odour, becoming itself 'perfumed,' while the grease again becomes odourless. Thus is procured the essence of jasmine, essence of orange-flowers, essence of violet, and others already named, rose, tuberosa, acacia, and jonquill. It is right to mention that the reason for producing a pomade—these scented fats are technically termed pomades—by distilling essential oil obtained by the distillation of orange-blossoms with water has not, in the least degree, the odour of the orange-blossoms from which it is obtained. The otto in fact undergoes a chemical change, and is no longer 'spangled' as far as odour is concerned. It is called Neroli, and is valued at from £16 to £20 the lb. weight, the variation depending upon the crop, which is of course greatly influenced by the season. The same remarks apply, though in a less marked degree, to rose. Since the rise in the cost of the rose industry may be gained from the following summary showing the weight of these particular flowers grown in the south of France in 1889:

<table>

The seat of the rose industry for the production of otto of roses is Bulgaria, more especially the cantons of Kezanlik and Karlova. Here no less than 5600 lb. were produced in 1889 at an average value of 20s. per oz.

**Perfumes of Animal Origin.**—Only four of these are used in perfumery—viz. Musk (q.v.), Ambergris (q.v.), Civet (q.v.), and Castor (q.v.).

The aroma of musk freely imparts odour to every body with which it is in contact. Its power to impart odour is such that polished steel will become perfumed. If a small amount of musk is placed in a box where there is musk, contact not being necessary, in perfumery manufacture tincture of musk is mixed with other odorous bodies to give permanence to the more evanescent perfumes or bouquets. This musk acting to them almost as a virulant does to a dysenteric. The usual statement as to the length of time that musk continues to give out odour is exaggerated. If fine musk be spread in thin layers upon any surface, and fully exposed to a changing current of air, all fragrance, it is said, will be gone in from six to twelve months. The finest musk, that which indeed is only really useful in perfumery, is distinguished as Tonquin musk, the average price of which is about 90s. per oz.

Civet is exceedingly potent as an odour, and when pure, and smelled at in the bulk of an ounce or so, is utterly insupportable from its nauseousness; in this respect it exceeds musk. When, however, civet is diluted so as to afford but minute quantities to the olfactories, then its sweet perfume is generally used. We learn, that the fragrant musk is the same as that breathed by the beautiful narcissus. Civet is extensively used duly attenuated in perfumery. Its powerful and lasting odour enables it to be used in soaps, and especially in satchets. It is one of the perfumes of 'Spanish Leather,' or Peau d'Espagne; the first gloves used in England were scented with it. Several thousand ounces are annually imported, the average price of which is about 7s. per oz.

Caster is in our day said to be almost obsolete as a perfume, but in former times, or although it cannot be largely used in any given perfume on account of the almost blackness of its tincture, still when properly diluted it is extensively employed. Its perfume, when old, especially, is exceedingly pleasant, and its fixing power is at least equal to that of musk. About 1500 lb. of castor are annually imported, which fetch on the market about 36s. per lb.

Of late years the progress of scientific chemistry has led to the production of numerous odoriferous substances, some identical with the active odoriferous principles of plants. Among them may be mentioned vanillin, the principle of vanilla (methyl protocatechualdehyde); commarou, of Tonquin bean (commiric anhydride), and many derivatives of phenol; but the majority of this class of bodies are more used in confectionery for flavouring than in perfumery. The artificial musk of L. Bauer is a delightful perfumy substance, and has many applications in perfumery; but it differs widely in odour from true musk.

The perfumes or bouquets of the shops are really mixtures of some or several of the primitive odours of the two above-mentioned groups. An example or two will illustrate this. 'Jockey Club Bouquet' is thus compounded: 2 gal. extract of orris, 3 gal. each of cassia, rose, and tuberosa pomades; 4 gal. civet; 7 gal. musk; 1 gal. spirits of wine; 8 oz. bergamot otto; 1 oz. rose. 'White Rose' consists of 1 gal. pomade, 1 pint spirits of wine; 1 pint essence of jasmine; 1½ pint spirits of wine; ¾ oz. rose otto; 1 drm. patchouli otto. It is obvious that the possible variety is infinite, since there are some sixty or more primitive odoriferous substances.

**Pergamus, or Pergamum,** anciently a city of Mysia in Asia Minor, on the river Caicus, 15 miles from its mouth. According to tradition, the place was founded by Greeks from Arcadia. It first acquired prominence when Lyons, one of Alexander's generals, chose it as a stronghold in which to keep his treasures. Under Philaretus, his eunuch, whom he appointed guardian of his treasures, it became the capital of a state, 283 B.C., under Cleitus I., and was the seat of independence against the Seleucids, although the title of king was first assumed by Attalus I, who reigned from 241 to 197 B.C., and defeated the Gauls in a great battle. He intimately allied himself with the Romans against Philip of Macedon, and this alliance subsisted throughout succeeding reigns, during which the kingdom continued to increase in extent and importance. Attalus III, surnamed Philometer, who died in 133 B.C., left it to the Romans, and under them it was one of the chief cities of Asia Minor. The native kings had
Periglese, Giovanni Battista, Italian musician, was born at Jesi, near Ancona, on 3d January 1716, studied music at Naples, and struck up a melodic style for himself. His first great work was the oratorio of San Gregorjmo, composed in 1731, in which year appeared his bright and tuneful oratorio of La Sera Padrona. This his masterpiece; it was revived in London in 1753. In 1766 he wrote another oratorio of the Church of Loreto. In consequence of delicate health he removed to Pozzuoli, where he composed the cantata of Orfeo and his second masterpiece, the pathetic Student Mater, but died immediately afterwards on 16th March 1786. Besides the works quoted above, he composed numerous operas, oratorios, and other sacred pieces.

Peri, according to the mythical lore of the East, a being begotten by fallen spirits, which spends its life in all imaginable delights, is immortal, but is for ever excluded from the joys of Paradise. It takes an intermediate place between angels and demons, and is neither male or female. So far as we have seen only female Peris, as is supposed by some, and these the wives of the Devis, the Peris live, on the contrary, in constant warfare with these Devis. Otherwise, they are of the most innocent character to mankind, and, just like the fairies with whom our own popular mythology has made us familiar, are when female of surpassing beauty. They belong to the great family of gentii, or Jinn (see DEMONOLOGY).

Perigun, a large cane composed of the trunks of two trees, hollowed and united into one handle; when an ordinary cane is formed of the body of one tree only.

Perianth. See FLOWER.

Pericardium, a conical membranous sac containing the heart and the commencement of the great vessels, to the extent of about 2 inches from their origin. It is placed with its apex upwards beyond the sternum in the interval between the pleurae, the serous sacs in which the lungs are enclosed, while its base is attached to the diaphragm. It is a fibrous-serous membrane, consisting of an external fibrous and an internal serous layer. The outer layer is a strong, dense, fibrous membrane, while the serous layer invests the heart, and is reflected on the inner surface of the fibrous layer. Like all serous membranes, it is a closed sac; its inner surface is smooth and glistening, and secretes a thin fluid which serves to facilitate the natural movements of the heart. It is inflammation of this memlbranes or serous sacs which constitutes the disease known as pericarditis.

DISEASES OF THE PERICARDIUM.—Pericarditis is a disease of frequent occurrence; the result of a very large number of post-mortem examinations being, that one out of every twenty-three of all who die at an adult age exhibits traces of recent or old attacks of this disorder. The first change which takes place in an inflamed pericardium is a dulling of its glistening surface, with some congestion, which is speedily followed by effusion into the sac. The effusion is sometimes almost entirely fibrous, in which case it coagulates, and gives rise to adhesions between the heart and the pericardium; or it may consist almost entirely of serum, which remains liquid; or it may be a mixture of the two. In a few cases it rapidly becomes purulent. In the cases that prove fatal when fibrous fluid has been effused, but has not coagulated to such an extent as to cause complete adhesion of the heart to the pericardium, the partially coagulated fibrous or liquid is seen to be of a yellowish-white colour, and to occur in a rugged, shaggy, or cellular form. Lacenae compared the surface on which the lymph is deposited to that which would be produced by suddenly separating two flat pieces of wood between which is the layer of butter had been compressed. When the patient dies at a more advanced stage of the disease—viz., soon after the whole of the membrane has become adherent—incipient blood-vessels, in the form of red points and branching lines, are seen, indicating that organisation is commencing in the deposit, which if death had not ensued would have been finally converted into cellular or acellular tissue, and might have occasioned the complete obliteration of the pericardial cavity.

The recognition of the disease depends almost entirely on the signs revealed by inspection and percussion. The earliest is generally the friction-sound, or to and fro murmur, caused by rubbing together of the roughened surfaces, and heard to accompany the heart's action; but if fluid is effused it may speedily disappear. In this case percussion of the chest shows that the dull area occupied by the heart is larger than normal, while the impulse of the organ on the chest-wall cannot be felt. The symptoms, besides those common to all inflammations, are extremely variable; in some cases where pericarditis comes on in the course of other serious disease the patient makes no complaint, and the complication is only discovered during the routine examination of the chest. But there may be intense pain and tenderness on pressure in the region of the heart, great irregularity or feebleness of the heart's action, distressing breathlessness, deafness, &c.

Pericarditis is a disease which occasionally runs a very rapid course, and terminates fatally in forty-eight hours or less. In ordinary cases, however, which terminate in apparent recovery, the disease generally begins to yield in a week or ten days, and, exceptions apart, adhesion usually appears to be complete in three weeks or less. If the adhesions which have formed are dense and fibrous, they may impede the heart's action and lead to serious symptoms at some subsequent period.

Pericarditis rarely occurs as an independent disease. It may result from extension of an inflammation in a neighbouring organ, pleura, ribs, &c. It is an uncommon result of a contaminated state of the blood, such as occurs in the exanthemata, especially scarlatina, and Bright's disease of the kidney; but, beyond all parison, it is of most frequent occurrence in association with acute Rheumatism (q.v.), of which it forms one of the most serious complications. It is often associated with inflammation of the muscular sacs around the heart, and, especially in rheumatism, of the lining memlbranes as well as the pericardium. The treatment of pericarditis at present in favour is much less active than when bleeding, mercurialisation, &c. were considered necessary. Complete rest in bed, light diet, with opium or other sedatives as necessary. In some general cases the disease is suited with that which the pericarditis is associated; local application of poultices or cotton-wool, sometimes of leeches or blisters, are the chief measures
PERICLES was the ancient either the Athens. extending order strong The the the name favour his century ^litical A shadow Three 457

Pericarp. See Fruit.

Pericles, the greatest statesman of ancient Greece, was born of distinguished parentage in the early part of the 5th century B.C. His father, in the Xerxes, the limit of the Persian at Mycale, 479 B.C.; and by his mother, Agariste, the niece of the great Athenian reformer Cleisthenes, he was connected with the princely line of Sicyon and the great house of the Alcmeonid. He received an elaborate education; but of all the teachers one whom he most revered was the serene and humane philosopher Anaxagoras. Pericles was conspicuous all through his career for the singular dignity of his manners, the Olympian grandeur of his eloquence, as 'majestic intelligence,' in Plato's phrase, his sagacity, his liberality, and his marked benevolence to his fellow-men. Both in voice and in appearance he was so like Pisistratus that for some time he was afraid to come forward in public life. When he entered on public life Aristides had only recently died, Themistocles was an exile, and Cimon was fighting his battles for the Athenian colonies. Although the family to which he belonged was good, it did not rank among the first in either wealth or influence, yet so transcendent were the abilities of Pericles that he rapidly rose to the highest power in the state, the leader of the dominant democracy. The sincerity of his attachment to the popular party has been questioned, but without a shadow of evidence. At anyrate the measures which either personally or through his adherents he brought forward and caused to be passed were always in tenor of extending the privileges of the poorer class of the citizens, and, if he diminished the spirit of reverence for the ancient institutions of public life, he enlisted an immense body of citizens on the side of law. He extended enormously, if he did not originate, the power of the Areopagus as a court of justice for citizens as well as for foreigners. He took steps for the military service, for acting as dikeut and in the Ecclesia, and the like, as well as for admission to the theatre—then really a great school for manners and instruction. Pericles seems to have grasped very clearly, and, to have held on to the modern radical idea, that, as the state is supported by the taxation of the body of the citizens, it must govern with a view to general interests rather than to those of a caste alone.

About 463 Pericles, through the agency of his follower, Ephialtes, struck a great blow at the influence of the oligarchy, by causing the decree to be passed which deprived the Areopagus of its most important political powers. Shortly after the democracy obtained another triumph in the ostracism of Cimon (401). During the next few years the ostracism of Pericles is distinctly intelligible to us, but it is safe to say that in general his attitude was hostile to the desire for foreign conquest or territorial aggrandisement, so prevalent among his ambitions fellow-citizens. Shortly after an obstinate war in which he showed conspicuous courage, Pericles majestically carried the measure for the recall of Cimon. His successful expeditions to the Thracian Chersonese, and to Sinope on the Black Sea, together with his colonies planted at Naxos, Andros, Eresus in Euboea, Itea in Macedonia, and Aegina, as well as at Thurii in Italy and Amphipolis on the Strymon, did much to extend and confirm the naval supremacy of Athens, and afford a means of subsistence for her poor. But his greatest project was to form in concert with the other Hellenic states a grand Hellenic confederation in order to put an end to the mutually destructive wars of kindred peoples, and to make of Greece one mighty nation, fit to front the outlying world. The idea was not less than it was enormous. But its accomplishment the semi-barbarous Macedonians would have menaced the civilised Greeks in vain, and even Rome at a later period might perhaps have found the Adriatic, and not the Euphrates, a limit of its empire. But the Persians were utterly incapable of appreciating such exalted patriotism, or of understanding the political necessity for it, and by their secret intrigues the well-arranged scheme was brought to nothing. Athens and Sparta were already in that mood towards each other which enabled the disaster of the Peloponnesian war inevitable. When the Spartans in 448 restored to the Delphians the guardianship of the temple and treasures of Delphi, of which they had been deprived by the Phocians, the Athenians immediately after marched an army toward him who had been deprived of it. But later an insurrection broke out in the tributary Megara and Euboea, and the Spartans again appeared in the field as the allies of the insurgents. The position of Athens was critical. Pericles wisely declined to fight against all his enemies at once. A brigade of ten talents sent the Spartans home, and the insurgents were then thoroughly subdued. The thirty years' peace with Sparta (445) left him free to carry out his schemes for the internal prosperity of Athens.

Cimon was now dead and a successor in the leadership of the aristocratic party by Thucydides, son of Melesias, who in 444 B.C. made a strong effort to overthrow the supremacy of Pericles by attacking him in the popular assembly for squandering the public money on buildings and in festivals and amusements. Thucydides made an effective speech; but Pericles immediately rose and offered to execute the buildings at his own expense, if the citizens would allow him to put his own name upon them instead of theirs. The sacrifice was successful, Thucydides was restored, and the oligarchic party resigned the undisputed master of the public policy of Athens. During the rest of his career 'there was,' says the historian Thucydides, 'in name a democracy, but in reality a government in the hands of the first man.' And the Athens of his day was the home of Aeschylus, Sophocles, Euripides, Anaxagoras, Zeno, Protagoras, Socrates, as well as Myron and Phidias; while there flourished at the same time, but elsewhere in Greece, Herodotus, Hippocrates, Pindar, Empedocles, and Democritos. The centre of this splendid group was Pericles, of whom the truthful pen of Thucydides records that he never did anything unworthy of his high position, that he did not flatter the people or oppress his adversaries, and that with all his unlimited command of the public purse he was personally incorruptible. Soon after this the Samian war broke out, in which Pericles gained high renown as a naval commander. This war originated in a quarrel between Miletus and the island of Samos, in which Athens was led to take part with the former. The Samians defeated the Athenians, but were in the end overthrown, and peace was concluded (439). The position in which Athens then stood towards many of the Greek states was peculiar. Since the time of the Persian invasion she had been the leader of the confederacy formed to resist them, but the destruction of the Persian power and the guardian of the confederate treasury kept in the isle of Delos. Pericles caused the treasury to
be removed to Athens, and, commuting the contingents of the allies for money, enormously increased the contributions to the patriotic fund, Athens herself undertaking to protect the confederacy. The grand charge against Pericles is that he applied the money thus obtained to other purposes than those for which it was intended; in short, he adorned and enriched Athens with the spoils of the allied states. To his mind Helles was subordinate to Athens, and he confounded the splendour of the dominant city with the splendour of Greece in a manner possible to a man of poetic imagination, but not to a statesman like the Great Helles. His enemies, who dared not attack himself, struck at him in the persons of his friends. Phidias was flung into prison for the impurity of introducing portraits of himself and Pericles into the battle of the Amazons depicted on the shield of the goddess Athena in the Parthenon; the brilliant Aspasia, the famous mistress of Pericles, was arraigned on a charge of impurity, and only acquitted through the eloquence of Pericles on her behalf; while the aged Anaxagoras was driven from the city.

To give a detailed account of all that Pericles did to make his native city the most glorious in the ancient world, Greek architecture and sculpture under his patronage reached perfection. To him Athens owed the Parthenon, the Erechtheum, left unfinished at his death, the Propylaeum and Grecian art, and patrician and sacred edifices; he also liberally encouraged music and the drama; and during his rule industry and commerce were so flourishing a condition that prosperity was universal in Attica.

At full length in 431 the long foreseen and inevitable Peloponnesian war broke out between Athens and Sparta. The plan of Pericles was for Athens to follow a defensive attitude, to defend the city itself, leaving Attica to be ravaged by the enemy, but to cripple the power of Sparta by harassing its coast. The story of the war is told elsewhere; here it is enough to say that the result was fatal to Athens for reasons for which Pericles was only in small part to blame. He trusted in the ultimate success of Athens both from her superior wealth and from her possessing the command of the sea, but he had not foreseen the subsequent deterioration in her citizens' spirit, nor upon the military courage of the Boeotian and Spartan infantry. Nor was his advice to keep behind the city walls rather than face the enemy in the field best calculated to rouse the Athenians' courage. The plague ravaged the city in 429, and in the autumn of the following year, Pericles himself died after a lingering fever. His two sons had been carried off by the plague; he had been harassed by a charge of peculation brought by Cleon, and the actual infestation of a fire by the diarrhea, while he had been without office from July 430 to July 429, but before the last he recovered his hold over the Ecclesia, and was gratified in the closing days of his life by the legitimation of his son by Aspasia.

As a statesman his greatest fault was a failure to foresee the ultimate ruinous to a nation. He taught the people to follow a leader, but he could not perpetuate a descent of leaders like himself. Hence we cannot wonder, when days of trouble broke over Athens, that men spoke bitterly of Pericles and all his glory. Yet he was a lofty statesman, inspired by noble aspirations, and his heart was full of a noble love for the city and her citizens. Plutarch tells the story that as he lay dying and apparently unconscious his friends around his bed were passing lighted torches over his great achievements of his life, and the nine truphies which he had reeived at different times for so many victories. The dying patriot quietly interrupted with the characteristic sentence—"What you praise in my life belongs partly to good fortune, and is, at best, common to me with many generals. But that of which I am proudest you have left unnoticed—no Athenian has ever put on mourning through any act of mine."

For his life and character, see Thucydides and Plutarch; the histories of Greece edited in 1817 by W. Watkin; the excellent study by Evelyn Abbott in the 'Heroes of the Nations' series (1891).

**Periplus.** See IGNOUS ROCKS.

**Perier.** CASIMIR, French politician, was born at Grenoble, 21st October 1777. A Parisian banker, he was minister in 1817 under the policy of the ministry, and thereby won a seat in the Chamber of Deputies. In 1828 he held the portfolio of finance under Martignac, but resigned it in August of the next year. Having taken an active part in the July revolution (1830), he was rewarded with a seat in the cabinet, but without a portfolio. When, however, Laffitte became President of the Council (November 2), Perier undertook the presidency of the Chamber of Deputies. On 13th March 1831 he succeeded Laffitte as minister; he sternly repressed all attempts at revolution, and governed by the "juste milieu" policy. He died of cholera, 16th May 1832. For his son, see CASIMIR-PERIER.

**Perigee.** See MOON.

**Périgueux,** a town of France, formerly capital of Périgord, now in the department of Dordogne, and situated on the right bank of the Isle, a tributary of the Dordogne, 95 miles by rail NE. of Bordeaux. It consists of the ancient city, which is gloomy in aspect and has narrow streets, with numerous houses and other remains of medieval and Renaissance architecture, and the Puy St Front, which until 1269 was a separate and a rival town. The cathedral of St Front is a Byzantine edifice, said to be a copy of St Mark's at Venice, built in 894-1047, but spoilt by 'restoration' in 1865. The town museum is especially rich in Roman and other antiquities. Statues of Montaigne, Fénelon, and the soldiers Danneaus and Bugeaud adorn public places in the town. Iron is mined and worked, and woolens are manufactured. The central park is a "bois de Périgueux," made of par- tridges and truffles, are largely exported. Pop. (1801) 30,725. Périgueux, a town of the highest antiquity, is the Gallic Vesunna mentioned by Caesar. The Romans built another town on the opposite side of the river at the junction of five Roman roads. Cluny was founded in the following century, and remains of a vast amphitheatre, aqueducts, baths, and temples. The tower of Vesunna is the most remarkable fragment of Roman architecture. It is 80 feet high, 200 feet in circumference, and has walls 6 feet thick, but has neither doors nor windows. Its purpose is not known. The district of Périgord is noted for its Caves (q.v.) and archaeological finds. See FLINT IMPLEMENTS.

**Periation (Gr. peri, and hélio, 'the sun'), that point in its orbit at which a planet is nearest the sun. See PLANETS, ORBIT, APHELION.

**Perin.** a barren island, and coaling and telegraph station belonging to Britain, situated in the Strait of Бз-Ель-Мандеб, at the southern entrance to the Red Sea, 97 miles W. of Aden, 13 from the Arabian shore, and 9 from the African. It is about 33 miles long by 24 wide, and crescent shaped; the two horns embracing a deep and spacious harbour. The island was visited by the British in 1799-1800, and was again occupied in 1857. In 1857 it was made a coaling station, and soon began to be a rival to Aden. The island is under the jurisdiction of the governor of Bombay Presidency. Pop. about 400, mostly coolie cool- hearers. See H. Spallanzani, Perin as it is (1880).
Perinæum

Perinæum, the floor of the human pelvis. The anterior portion, situated in front of the anus, is called the true perinæum, or urethral portion of the perinæum; the posterior portion is called the anal portion or ischio-rectorial region.

Period and Periodicity. One of the most striking features of the ordinary phenomena of nature is their tendency to recur and repeat themselves in a similar manner indefinitely; and in general this repetition takes place at regular intervals and practically equal intervals of time. The day, the month, the year are familiar examples of such periods, corresponding respectively to the earth's rotation, the moon's phases, and the phases of the sun. As a factor in human life the year is especially traced out by the climatic changes that accompany its progress, but strictly speaking it is the period determined by the recurring configurations of earth and sun. Many periodic phenomena of importance, such as eclipses, transits, occultations, depend on the moon's phases on the one hand; and long before Newton's law of gravitation gave the key to the cosmic universe the periods of some of these had been discovered. See ECLIPSE (with its various cycles—the metonic period of 19 years, the Saros period of 76 years, &c.), CYCLE, DAY, ECLIPSES, YEAR, &c.

When we look into the minute mechanism of nature we find here also the same prominence attached to periodic qualities. Sound and light may be classed as a vibratory or oscillatory motion of some sort; and an accurate time periodicity of these motions we trace our sensations of harmony in music and colour. In certain respects, however, the periodicity is imperfect, each period not being an exact reproduction of its predecessor. The tuning-fork or pianoforte-string vibrating freely in a perfectly lossless vibratory character, and its motion steadily damped by the air, is an exception, and yet, judged by the pitch, the frequency, or time periodicity remains the same throughout. In these similar cases viscosity (q.v.) ultimately transforms the vibratory energy into heat (see ENERGY). Heat itself is believed to be of the kind of vibratory energy of the molecules; and the spectroscope demonstrates that intense heat is certainly associated with definite periodic motions, giving rays of corresponding periodicity (see SPECTRUM).

Passing now to the other extreme, we find prominently in astronomy, instances of long periods, some of which have not been completed within historic times, but of which the evidence is incontrovertible. The recession (q.v.) of the equinoxes and the slow changes in the eccentricities and inclinations of planetary orbits may be mentioned by way of illustration. The geologist also has found evidence of periodic changes in the climatic situations of the earth (see GLACIAL PERIOD, PERIODICITY). Geomagnetic periodicity involves the idea of time, but we are not aware of the periodic qualities depending on position or on grouping. A very good example of this is the periodic law of modern chemistry (see ATOMIC UNITS, also WAVES).

Life is as full of periodic phenomena as animate nature; but the increasing complexity of conditions makes the periodicity still less perfect. In the beating of the heart, in the alternation of breathing and sleeping, of hunger and satiety, we have examples of vital actions with a distinct periodic character.

Periodicals. Everything is a periodical that is published periodically. Every publication that is published more than once is necessarily published periodically. Therefore every publication, excepting a book complete in itself, may, strictly speaking, be described as a periodical, from the Times to Whittaker's Almanac and the Post-office Directory. The use of the term is, however, restricted in ordinary conversation to magazine or reviews appearing not less frequently than once a quarter, and not more frequently than twice a month. Weeklies, at least in Great Britain, have with a few exceptions ceased to be regarded as periodicals. As we have no set of successive issues, our periodicals may be said to be practically reduced to monthlies and quarterlies.

The refusal of the English-speaking world to tolerate fortnightly publications is as remarkable as if it is unnatural. In France and Italy and Belgium the fortnightly is regarded as the natural form of the high-class periodical. Outside these countries the fortnightly is practically unknown. Neither in Great Britain, nor in Greater Britain, has it been found possible to acclimatise the fortnightly. In Russia, in Germany, in Scandinavia, and in Spain and Portugal the periodicals are monthly. As if to remind the world of the constitutional incapacity of the English race to take its literature in bimonthly instalments, the Fortnightly Review is published monthly, but religiously announces on every cover that the issue of the 15th is suspended.

The number of periodicals is almost numberless. There are 332 monthlies in Italy alone, of which, at a moderate computation, 300 are read by no one monthlies in Italy, and by probably fewer than 300 subscribers within the peninsula. But the number of periodicals of general interest that are worth reading or the periodicals are comparatively few. In Italy, for instance, there are hardly more than three which the outsider world ever heard of. In France there are not more than four or five. Different countries exceed in different departments. It is in the literature and criticism the Revue des Deux Mondes has the first place. For illustration America leads easily, distaining all rivals with the Century, Scribner's, Harper's; while in the second rank, although still ahead of foreign competitors, with one exception, come the Cosmopolite, the New Monthly, the Foreign Magazine. The only exception is the German magazine, Vehag en und Klaasen's Neue Monatshefte. For general interest and solidity combined the English periodicals and monthly miscellanies rank first, although they are habitually proselytised by the Nouvelle Revue, the North American Review, the Forum, and the Arena. For bulk the Russians surpass all the magazines and reviewers of the world. The Russian monthly contains about three times as much printed matter as the Nineteenth Century. In proportion to its size Belgium leads the world in the multiplicity of its periodicals; but their prosperity is in an inverse proportion to their numbers. There is only one Portuguese monthly procurable in London.

The genesis of the periodical can be traced back for centuries, but the earlier publications of the kind bear about as much resemblance to the magazines and reviews of to-day that the colliery bears to the winner of last year's Derby. The evolution of the modern magazine is usually traced back to the Philosophical Transactions of the Royal Society, which began to appear in 1665, but the true progenitor of our monthly miscellanies were the pamphlets which were spawned in such numbers in the heat of the revolutionary ferment of the 17th century. There was no regular periodicity in their appearance. Pamphleteers wrote as the spirit moved them, but their intermittent productions, in everything excepting the regularity of their appearance and the fact that each appeared singularly instead of being stitiched together with a dozen others, correspond very closely to the
monthly miscellanies which have now become the forum of civilisation. Milton, Marvell, and Defoe
would all have been regular contributors to our
monthly miscellanies. The editorship of these publications had existed in their
time. As they were without those con-
veniences of a more complex civilisation they were
under the necessity of publishing each of their
effects separately, often at their own risk, and very
seldom to their own profit. In its last and depri-
mant stage the middleman has been found indispensable alike for the profit of the
producer and the convenience of consumers.
The modern review is the monthly market where
author sells their wares, and of late the excessive
multiplication of weekly journals has led to the publica-
tion of a kind of clearing-house of periodical litera-
ture in the Review of Reviews in London and New
The history of periodical literature in the 18th century as usually told in encyclopedias is little
better than a parade of epistles from the tombs of defunct reviews. Two notable facts, however,
stand out clearly discernible on these sepulchral tablets. The first, the literary position
achieved for the first time to periodical publications by Addison's editorship of the Spectator, although
it was no less than seven months that the impres-
sion, the first monthly magazine of the modern type, when Cave the pub-
lisher brought out the Gentleman's Magazine in 1731.
Of the Weekly Memorials for the Ingenious,
published for twelve months in 1748, or the Gentle-
man's Journal, a Monthly Miscellany which appeared in 1792, nothing need be said. The
Gentleman's Magazine, after making a fortune for
its originator, has continued to flourish ever since.
If England may claim the honour of having in-
volved, with the assistance of Sydney Smith and a
few less gifted Southern, decided to establish the
Edinburgh Review (q.v.) in Whig interest in 1802. Their enterprise was rewarded by an in-
mediate and signal success. The wit, the talent, the
audacity, and the sheer impudence of the young
reviewers startled the limited world of letters from
centre to circumference, and convinced the Tories in
Scotland that it was impossible to counter the blue and yellow organ of
militant Whigerry by a quarterly of unimpeach-
able orthodoxy. Thus it was that of the Edin-
burgh was born the Quarterly (q.v.), and the
two great periodicals have held the field ever since as the
most authoritative exponents of the most respect-
able and scholarly element of the two great parties.
The honour of initiative in these matters was not
confined to the Scottish Whigs. Fifteen years after
the Edinburgh first made its appearance a Scottish
journal on the other side, William Blackwood by
name, achieved fame and fortune by an unqualifiedly
happy stroke in the publication of Blackwood's
Magazine, a half-crown monthly which may be
regarded as the parent of the political monthly
miscellany. Blackwood was to the Edinburgh and
the Quarterly what the breeze was to the stately
drake. It appeared twelve times yearly, against their four numbers; it was infinitely
more varied. It published serial fiction, poetry,
prose, and that marvellous symposium, the Notes
and Queries, a secret of which perished with
the author, Christopher North. This was again expelled by
the other side to resort to the publication of periodicals which
are for the most part not only dead, but for-
gotten. The post Campbell did his best in Col-
burn's Monthly, but for a dozen years the ascendency of the
torrential but brilliant Meg was undisputed.
Then in 1830 came Fraser—a magazine which,
then in many visits under many editors, is now
acknowledged as in other parts of Great Britain
brutally tulipulent in its Toryism than of yore, but
still bright, brilliant, and scholarly.
The Scottish initiative so remarkably asserted in the
Edinburgh among the quarterlies and Black-
wood among the monthlies was not exhausted. In 1832
the New Monthly Journal was, and in 1850,
marking the commencement of a new and more
popular phase of magazinedom. It was published
weekly, but was also issued in monthly parts.
More than half a century has passed, and Chambers
is still 'familiar in our monthlies as housewords,'
Cassells' Family paper (now known as The
Family Magazine) was not started till 1833. The
old Penny Magazine (1829), published by the Society
for the Diffusion of Useful Knowledge, deserves
honourable mention. It was succeeded by the
Leisure Hour in 1852, still one of the best illus-
trated Expendtes, published by the Religious Tract
Society. Charles Dickens founded Household
Words in 1850, and All the Year Round in 1859.
In 1859 Macmillan—again a Scott—published the
first shilling magazine. This new departure was
rapidly followed by the publication of monthly
under the editorship of William Thackeray, which at once
achieved a phenomenal success; of Temple Bar,
edited by George Augustus Sala; and of London
Society, which has always relied chiefly upon fiction
for its circulation. In 1855 George Henry Lewes founded the Fort-
nightly Review, an avowed imitation of the Revue des
Deux Mondes. It was started as a medium for the dis-
cussion of subjects which interest cultivated and
thoughtful readers, and it was to be published at
intervals 'neither too distant for influence on
passing questions, nor too brief for deliberation.'
Mr Lewes was soon succeeded by Mr John Morley,
who, in the sixteen years during which he was editor,
gave a distinctive character to the new periodical
literature of our time. The success of the Fortnightly
led to the publication of the Contemporary (1866),
the rival paper to the Fortnightly, and the two
together were called the 'battle of the Press,' as the
Fortnightly was biased in favour of Anac-
ticism. This again was followed eleven years later
by the publication of the Nineteenth Century, a miscel-
Ilaney entirely free from editorial bias of any kind.
These three reviews have a practical monopoly of the
field. They claim as neighbors or rivals
—they can hardly be described as either rivals or
competitors—the National Review (1833), which is
Conservative; and the Westminster, which, origin-
ally founded in 1824 as a quarterly, was converted
in 1887 into a monthly, while still remaining true
to its original philosophical Radical principles.
All these are published at half a crown. Most of
them publish both signed and unsigned articles—
the Nineteenth Century alone has consistently
refused to insert any article not signed by the real
name of the author. The circulation of the Nin-
teenth Century does not quite reach the half-
crown review with more than 12,000 subscribers.
In 1850 the Monthly Packet was founded by
Miss Yonge; it is written for young girls.
Another Church of England shilling magazine was the
Newbury House Magazine, issued from 1839
onwards. The New London Magazine was
founded in 1844. In 1869 Good Words, founded by Mr Stahan, under the editorship of Dr
Norman Macleod, achieved so great a success as a sixpenny monthly, that it was followed in
1864 by the publication of the Sunday Magazine,
edited by Dr Guthrie. The prosperity of the six-
penny led to the extinction of some of the older
magazines. The English Illustrated Magazine,
started in 1833, has repeatedly changed its manage-
ment.
sixpence. In the years 1887-89 Murray's Magazine appeared at a shilling. In 1900 the Review of Reviews appeared at sixpence, followed in 1891 by the Strand Magazine. These magazines achieved in the first year of their publication circulations exceeding 100,000. The Idler, at first (1892) a sixpenny, now costs a shilling; the Poll Mall Magazine dates from 1893; the Woman at Home from 1894; the Windsor began in 1895. Crampton's (now Chapman's) Magazine is devoted to short stories; McClure's Magazine began in 1893; Cassier's Magazine (1891) concerns itself with industry. In 1898 Sir G. Newnes started The Wide World Magazine and The Home Magazine. The most widely circulated magazines, besides the Strand, Chambers's Journal, and Pearson's, are Harmsworth's, Royal Magazine, The Puritan, Boy's Own Paper, Girl's Own Paper, Quiver, Cassell's Family Magazine, The Young Man, The Young Woman, Leisure Hour, Sunday at Home, Good Words, and Sunday Magazine.

Among monthly periodicals devoted to art the chief is the Art Journal (1839). The Portfolio, founded by Mr Hamerton in 1869, is since 1894 a series of monographs on artists. The Magazine of Art (1878), The Artist, and The Studio are well known. Music is represented by the Musical Times and a few others, and the drama by the Theatre Review.

The geographical societies publish their proceedings, and most of the sciences have their own reviews; the National Review has a line of its own. The English Historical Review and The Scottish Review (1889) fulfill special functions. Cosmopolis (1884) is a magazine for the young, and there are innumerable religious magazines. The Catholic Church is represented by the Dublin Review (quarterly), the Month, the Lamps, the Lyceum, and St Peter's (1898). The Wesleyan Methodists and the Primitives publish quarterly; the Congregationalists have no longer the place in periodical literature they possessed when Mr Allen edited the British Quarterly and Yaxton Hool the Eclectic. The Jewish Quarterly is read by many who are not Jews. The Salvation Army has a monthly that is the War Cry. The largest is devoted to sport. There are monthly magazines devoted to astrology, postage-stamps, chess, cricket, cycling, vegetarianism, anti-vaccination, Malthusianism, spiritualism, theosophy, and mysterious psychical phenomena; and most trades have a periodical devoted to their interests.—Santa Lucia is the monthly for the blind, in raised Braille type. See Blue-Books.

A general idea prevails among the public that to write for the magazines is a sure and easy road to fame and wealth. Any one, except writers of popular fiction, the number of contributors to periodical literature, not holding editorial appointments, who make £200 a year out of the magazines might probably be counted upon the fingers of one hand. The best paid contributors to magazine reviews are other contributors. The average cost of a page of five hundred words is £1 a page of 500 words. The average review article does not yield its writer more than £15. As there are not ten men in England who contribute ten articles each a year to monthly miscellanies—the contemporary periodical—the total number of contributions rises ever higher. The late editor of the Forum recently calculated that he received from outsiders 3000 MSS. per annum, out of which he was usually able to use less than one per cent. 'Wham's the harm,' asked the Ettrick Shepherd in Noctes, 'o a few gude, sober, steady, judicious, regular, well-informed, versateele, and biddable contributors?' To this inquiry Christopher North replied, 'None such are to be found on earth—you must look for them in previous ages.' It would seem that the editorial burden has changed little in fifty years. Poetry in particular is a drug in the market. In the same Noctes Christopher North said, 'I seldom pay for poetry. In cases of charity and courtesy—that is to say of old women and young ones—by terms are arranged. A shilling, a sonnet, a dollar for a dramatic scene, and for a single book of an epic by way of a specimen, why, I do not grudge a sovereign.' This is probably more than the epic poet of our day would get for all his books from any magazine editor. Many periodicals, like hospitals, are supported entirely by voluntary contributions.

Of English-speaking lands the periodical flourishes chiefly in the United States. In the British colonies the English product seems to kill out the native productions. Beyond the very noteworthy periodical quarter in Sydney, and some diminutive religious magazines, Australia has no monthly magazines or reviews, except the quarterly Imperial Review of Melbourne. New Zealand has the Monthly Review. South Africa has produced no magazine of national pretensions; what had in the Bystander a unique magazine edited, written, and owned by Mr Goldwin Smith, but it no longer appears. Barbadoes has a little monthly in Exselsior; Honduras boasts the Hondurass Mining Journal, formerly Honduras Progress; and British Guiana publishes Timehri, a quarterly. Among the periodicals in English published on the Continent are the Enquiltine (Rome) and Anglo-Austria (Meran). India has the Calcutta Review (quarterly), and the monthlies, the Indian National Magazine, the Indian Magazine and Review, and the new Allahabad Review; but the publications of London and Edinburgh overshadow the periodicals of the rest of the empire. The Asiatic Quarterly now embraces colonial and African topics, otherwise the colonies are not excepted as by the daily mail. Among the periodically issued printed matter is conveyed by the mails at special rates not exceeding a halfpenny per pound. In England it costs 2½d. to send a half pound of printed matter, if published monthly, through the post from St. Martin's-le-Grande to Downing Street—although the post-office will carry a pound weight of printed matter if it is issued weekly for one halfpenny from Land's End to John o' Groats. This absurd method of handicapping monthly publications is unknown in the United States. The American periodical is distinguished for the excellence of their typography, and the clearness and artistic character of their illustrations. There are no such illustrated magazines as the Century, Scribner, and Harper published outside of New York. Munsey's (ten cents) has a circulation of 250,000. The American illustrated magazine is found throughout the British empire; the Century and Harper circulate largely in India. The Cosmopolitan has now begun to publish in London as well as in New York. The New England Magazine is also a well-illustrated monthly. Of the non-illustrated American magazines the Atlantic Monthly (1858) is one of the oldest and most respectable. Lippincott publishes monthly a complete novel of high character, with a selection of miscellaneous essays. All these are now
published simultaneously in London and New York. The three monthly reviews which correspond to the Nineteenth Century, Fortnightly, and Contemporary are the North American (1815), the Forum (1886), and the Arena (1888). The Arena accompanies its letterpress with portraits and occasional illustrations. It has a distinctive rôle of its own, being the arena for the free development of all the issues which seem to foreshadow the trend of progress. The Forum is steady, sensible, and instructive. The North American is more lively and up to date. All these publish signed articles. The Arena publishes stories. English writers contribute largely to the North American and the Forum. In theology there are the Anrioler Review, Homiletic Review, Church Review, American Catholic Quarterly, Catholic World, &c.

Up to 1891 some of the English reviews were in the habit of forwarding printed sheets to New York every month; but in order to get knowledge of the American reader concerning English periodicals has been gained from the pages of Little's Living Age and Current Literature, two publications which are freely fed from the pages of English magazines and reviews. The Americans produce copiously the most intelligent and the most numerous quarterly. They publish great on economics and education, and theology of the slightly antiquated pattern. Their Popular Science Monthly is one of the best of its kind, and the Chautauquan is quite unique—a magazine that might almost serve for a university.

Coming to foreign periodicals, the first place naturally belongs to France, whose two principal reviews, the Revue des Deux Mondes (1829) and the Revue de Revue (1879), are read throughout the whole Latin world. It is a curious fact that the Revue des Deux Mondes has more subscribers outside France than within the republic. There is a great Latin belt of a French reading public stretching from Madrid to Bucharest, and among them the Revue reigns as it has long reigned supreme. The Nouvelle Revue over its career has been more than a ribald for a university.

Germany has many literary capitals, and her magazines do not all emanate from a single centre. Most of the popular German magazines, such as Die Gartenlaube and Uber Land und Meer, are issued both weekly and monthly. They are copiously illustrated, and form a great contrast in their readableness to such ponderous reviews as the Deutsche Rundschau, the Deutsche Revue, Uner Zeit, and the Preussische Jahrbcher. Among the illustrated popular magazines, Tom Pobel zum Meer deserves a high place. The best of the German magazines is Schlegel's Klassiker's Neues Monatshefte, already mentioned, Westermann's Deutsche Illustrirte Monatshefte and Nord und Sud are also high-class magazines. German periodical literature is very rich in the original reviews, and several periodicals represent the various new schools of literature—e.g., the Gesellschaft is the organ of the Realists. Similarly the Moderne Rundschau, the Deutsche Dichtung, and others are conducted by members of the new schools and the old.

In Russia the weekly review forms the chief field for the manifestation of the literary talent of the nation. These reviews are published either at Moscow or at St. Petersburg. They are hardly seen outside Russia; they are not illustrated, and their circulation is comparatively small. In Italy the Nuova Antologia, La Rassegna Nazionale, and La Civiltà Cattolica are the only periodicals excepting those purely scientific or professional that are seen outside the peninsula. Spain has Espafia Moderna or Revista Ibero-Americana and Revista Contemporanea; Holland, De Gids, Vragen des Tijds, and Elsevier's Geistlirdre Maandschrift; Scandinavia, Tidsvaren, Svensk Tidskrift, Nordisk Tidskrift, &c.

In concluding this rapid survey of the periodical literature of the world, mention should be made of the latest born and most polyglot of monthlies, the Pantobiblon, a magazine published in St. Petersburg in no fewer than fifteen different languages. It aims at providing professional and scientific men of all countries with a clue to the periodical literature, technical and scientific, of all the world. It is like a periodical monument reared to the memory of the Tower of Babel.

Pouk's Index to Periodical Literature, a dictionary of the more important articles in the quarterlies, monthlies, and many weeklies, is edited by a Chicago librarian. Stead's popular Index to the Periodicals of 1890 has been issued in London, and the publication is to be continued annually. See also the articles Newspaper and Book Trade in this Dictionary.

Periopathamnus, a remarkable genus of acanthopterous fishes, allied to the gobies. Their eyes protrude and are very mobile; their pectoral fins can be used as legs. Several species occur on the coasts of the Indian Ocean and Western Africa; of these the best known is P. koelreuteri.

(From Hékson's Naturalist in North Celebes, 1890.)

This fish lives about low tide-mark on the muddy flats or among rocks, and by means of its pectoral fins and tail flaps along in search of crustaceans, insects, and gastropods. Respiration seems to be effected through the skin of the tail even more than by the gills. They cling by their fins to rocks and mangrove-roots, and keep their tails in the water; or they climb entirely out of the water, and jump with agility when disturbed.

Periopathitis, inflammation of the periostracum, the tough fibrous membrane which surrounds the various bones (see Bone). It generally occurs on the surface of thinly-covered bones, such as the tibia, clavicles, and cranial bones. Its chief causes are (1) a syphilitic taint; (2) rheumatism; and (3) serpula; but its occurrence is often determined by injury to the part. The affection, especially when due to the first or second of the above causes, is usually accompanied with considerable nocturnal pain. If the disease occurs in an acute form it must be treated with leeches, fomentations, and other ordinary antiphlogistic remedies. If severe, an incision through the inflamed tissue is sometimes the most effectual treatment.
Peripatetic Philosophy, a designation of the philosophy of Aristotle (q.v.) and of his followers. It is of doubtful origin, being supposed to have been derived either from his custom of occasionally walking about (peripatein) during the delivery of his lectures, or from the habit in which they were delivered being a shaded walk.

Peripatus, a genus occupying a unique position between myriopods and insects on the one hand and annelids on the other. For, along with the tracheae or air-tubes characteristic of insects, Peripatus has the nephridia or excretory tubes characteristic of annelids or earth-worms. The body measures about two inches in length, is shaped like that of a worm or caterpillar, but without external rings, bears numerous (14 to 124) imperfectly-jointed stump-like clawed feet, and has a soft skin, with little if that chitin which is abundant as a cuticular product in other arthropods. The head bears a pair of mobile antennae, a pair of mandibles in the mouth, and a pair of oral papillae from which slime oozes. With this Peripatus catches its prey of small insects, &c. The species live in moist places, and their habits are nocturnal in their habits. Professor Sedgwick says that it is the exquisite sensiteness and constantly changing form of the antennae, the well-rounded plump body, the eyes set like small diamonds on the side of the head, the delicate feet, and, above all, the rich colors and form with a child-like simplicity, are peculiar machine to give these animals an aspect quite exceptional beauty. There are many remarkable structural features: thus, the ventral nerves are widely separate; the eyes are simple, like those of an annelid; the body-cavity is divided into three longitudinal compartments, from which the cavities of the legs are furthermore distinct. The sexes are separate. The development varies considerably in different species, for the ova may contain a considerable amount of yolk or none at all. In several it has been observed that the cells of the embryos are for a prolonged period indistinctly separate from one another. The embryos develop within the body of the mother-animals; when born they resemble the parents except in size. The distribution is very wide; in South America four species, *P. caurinus, P. baffouri;* in New Zealand, *P.* *zoutendamia;* in Queensland, *P. lewiskii;* in Caracas, *P. edwardii;* and others from Demerara, Trinidad, St. Vincent, Chili, Quito, &c. The distribution, the structure, and the development of Peripatus all suggest that it is the survivor of an archaic type. The genus is usually dignified as a special class of Arthropods—Prototrichaeta. See figure under CATERPILLAR; and monograph by A. Sedgwick, Quart. Journ. Micr. Soc., xxviii. (1888).

Perissodactyla. See ARTIODACTYLA.

Peristaltic Motion, the action of the muscular coat of the intestines, by which the substances contained within it are regularly moved onward. See DIGESTION.

Peritonenum (Gr. peritonein, 'to extend around'), a serous membrane, and, like all membranes of this class, a slht sac, which, however, in the female is not completely closed, as the Fallopian tubes communicate with it by their free extremities. The peritonenum more or less completely invests the organs lying in the abdominal and pelvic cavities, and is reflected upon the walls of the abdomen, so that there is a visceral and a parietal layer. Numerous folds are formed by the visceral layer as it passes from one organ to another, giving rise to the parietal layer, and at the same time enclose vessels and nerves. Some of these folds are termed Ligaments, from their serving to support the organs. Thus we have ligaments of the liver, spleen, bladder, and uterum formed by peritoneal folds. Others are termed Mesenteries (from the Gr. meso, 'the middle,' and enteron, 'the intestine'), and connect the intestines with the vertebral column. They are the Mesentery proper, the ascending transverse, and descending meso-colon, &c. In the peritonenum, there are folds called Omenta, which proceed from one viscus to another. The great omentum always contains some adipose tissue, which in persons inclined to corpulency often accumulates to an enormous extent. Its use appears to be (1) to protect the bowels from infections, (2) to prevent the abdomen from being divided anteriorly as with an apron, and (2) to facilitate their movement upon each other during their vermicular action.

DISEASES OF THE PERITONEUM.—The peritonenum often becomes the seat of topical effusion, both in cases of general dropsy and in circumanthesis of the liver. It may also be attacked by cancer, either primary or secondary, and, like all the serous membranes, readily takes on inflammation from various exciting causes. This inflammation is termed Peritonitis, and may be either an acute or a chronic disease.

Acute Peritonitis, inflammation of the coating of the bowels, but often popularly spoken of as 'inflammation of the bowels,' generally presents well-marked symptoms. It sometimes commences without any pain in the abdomen is usually the first symptom. The pain is at first sometimes confined to particular spots (usually in the lower part of the abdomen), but it soon extends over the whole abdominal region. It is increased, on pressure, to such an extent that the patient cannot even bear the weight of the bedclothes; and to avoid, as far as possible, internal pressure upon the peritonenum, he lies perfectly still, on his back, with the legs drawn up, and breathes by means of the ribs, in consequence of the pain occasioned by the descent of the diaphragm. In inspiration. The breathing is naturally shallow in these cases, and, less air being admitted at each movement of respiration, the number of those movements is increased. There are perhaps forty or even sixty respirations executed in a minute, and the temperatute. The pulse is usually very frequence, often 120 or more; almost in the minute, and small and tense, though occasionally strong and full at the commencement of the attack; the temperature is usually raised, and vomiting is almost always an early symptom. After the disease has continued for a time, the belly becomes tense and swollen; the enlargement being caused at first by flatus, and afterwards also by the effusion of fluid, as may be ascertained by percussion and palpation. The progress of the disease is in general rapid. If fatal cases death usually takes place within a week, and often sooner. The symptoms indicating that the disease is advancing towards a fatal termination are great distention of the abdomen, a very frequent and feeble pulse, a pinched and extremely anxious appearance of the face, and cold sweats. Peritonitis rarely arises from exposure to cold alone. It is frequently the result of local violence, and of wounds penetrating the peritoneal sac, including various surgical operations. In the majority of cases it is due to extension of some inflammatory process, situated in the abdominal viscera, particularly the hollow viscera (stomach, intestines, gall-bladder, urinary-bladder, womb). It is sometimes caused by Bright's disease. Two varieties call for special mention: purperal peritonenum, due to the inflammatory inflammation of the lining membrane of the womb after child-birth or miscarriage, a most fatal form of disease; and peritonitis from perforation of one of the hollow
vessels, which is characterised by the suddenness of the attack, intense pain, incapable of mitigation by medicine, all at once arising in some part of the abdomen, the whole of which soon becomes tender in every part. This form of the disease is generally fatal, death usually ensuing within two days. In some, after which, there is vomiting for a few hours. Perforation of the small intestine, in consequence of ulceration of its glands, is of not uncommon occurrence in typhoid fever, and sometimes occurs in phthisis. That apparently useless structure, the vermiform appendage of the caecum, is the peculiar organ of perforation; sometimes it is the stomach which is perforated, and in these cases the patients are usually unmarried women (especially domestic servants), who may have previously appeared in good health, or at most have complained of slight dyspepsia.

At the onset of the disease it is not always easy to distinguish it from Colic (q.v.), but the progress of the case will soon settle the question. With this exception, the only disease with which peritonitis is likely to be confounded by the well-educated practitioner is a peculiar form of hysteria; but even in this case the presence of hysteria in other forms, and the general history of the patient and of her symptoms will almost always lead to a correct diagnosis of the disease.

The treatment of a case of peritonitis must depend upon the nature of the case, and in all it is of the greatest importance to keep the bowels at rest. But in some, particularly those following surgical operations on the female generative organs, the opposite plan, treatment by saline purgatives, intrinsically by Lavage. Taint, gives excellent results. The diet must be light and fluid; in cases of perforation of the stomach, no food or even drink must be given by the mouth. Light poultices, or hot fomentations, should be constantly applied to the abdomen; leeches are sometimes useful. In cases of perforation from disease or injury, and of supplicative peritonitis, life has frequently been saved during recent years by prompt surgical interference.

Chronic Peritonitis occurs in two forms, which differ widely as to their symptoms and mode of treatment, and yet are very similar in their symptoms. In the first the inflammation is of the ordinary character, and, although the disease sometimes originates spontaneously, it is more frequently the sequel of an imperfect cure of acute attack; in the second it depends upon tubercular inflammation, and it generally meets with in persons of a scrofulous constitution. The symptoms of chronic peritonitis are more obscure than those of the acute form. There is abdominal pain, often slight, and not always constant, which is increased by pressure, or sometimes felt only when pressure is made. The patient complains of a sensation of fullness and tension of the belly, although its size is not visibly increased; of a loss of appetite; and of nausea and vomiting; and the bowels are usually more or less out of order. After leaving the abdomen enlarges, and becomes tympanitic, and the ascitic fluid is elevated; and death gradually ensues from delirium and emaciation, unless the fatal issue is accelerated by an acute inflammatory attack. It is not always easy to determine, during life, whether the disease belongs to the first or second. When its origin cannot be traced to a preceding acute attack to local abdominal injury, or to chronic affections of the abdominal viscera, there is strong reason to believe it to be of the tubercular form, especially if the disease is of a constitutional nature. In the tubercular form of the disease, the tenden- cees of the patient point in the opposite direction.

Little can be done in the way of medical treatment, especially in the tubercular form, further than mitigating the most distressing symptoms, and possibly retarding the final issue, though recovery sometimes follows the continuous application of mercurial liniment. In chronic, even tuber- cular peritonitis, however, as in the acute disease, surgical interference, either by aspiration or by free opening of the abdomen is late, has given very encouraging results in many cases.

Periwinkle (Vinca), a genus of plants of the natural order Apocynaceae, having a 5-clawed calyx, and a saucer-shaped corolla bearded at the throat, with five obliquely truncated segments. The leaves are opposite and evergreen; the flowers grow singly in pairs near the axis of the stem. The Lesser Periwinkle (V. minor), a native of many parts of Europe and of the southern parts of Britain, growing in woods and thickets, is a half-shrubby plant with trailing stems, rooting at their extremities, ovato-lanceolate leaves, and pale-blue—sometimes white or reddish-purple—salver-shaped flowers. The Greater Periwinkle (V. major), which has much larger flowers and ovato-cordate leaves, is a native of the south of Europe, and is found in a few places in the south of England. Both of these species are very commonly planted as garden plants, usually being grown in gardens objects with pleasing green foliage, and producing their beautiful flowers at almost all seasons of the year, even in winter when the weather is mild. The Herbaceous Periwinkle (V. herbacea), a Hun- garian species, is remarkable for the abundance of its flowers. The Yellow Periwinkle (Vinca major) is a native of the southern parts of North America. The Rose-coloured Periwinkle (V. rosea), a native of Madagascar, is a favourite hothouse plant.

Periwinkle (Littorina), a genus of marine Gastropods, represented by several species on British coasts. The commonest, Littorina littorea, is abundant between tide-marks on the rocks, and is often collected and used for food. It is hatched in its shell, extracted as eaten, and is very palatable. Periwinkles crawl about under water, but usually remain passive when left uncovered by the tide. Without water they can survive for many hours, and then become unable to endure a considerable freshening of the salt water. They are very abundant in seaweeds, and are often useful in keeping beds of young oysters from being smothered. Periwinkles drawn up from 70 to 80 fathoms were first in 1889 used as bait for cod-fishing on the banks of New- foundland. The little white species is orpinous, but in the larger species it is usually thrown from the water mark, the young are hatched and have a hard shell before they leave the mother. These shells are apt to make this periwinkle gritty, and therefore it is not used as food. Among the struc- tural characters of the periwinkle the substantial shell of few whors, the closely-fitting, horny oper- culum, the nearly circular shell aperture without any siphon-notches are at once evident. Species of Littorina occur on almost all coasts, and there are about half a hundred in all. It should be care- fully noticed that, in the periwinkle, the periwinkle becomes the shell of the fish, when the fish is caught, and the shell is thrown off. The shell is then often called the Wilk, Wulk, or Whelk in Scotland, but it is not nearly related to the true whirls (Purpura, Bucephum, &c.). See WHELK.

Perjury is the crime committed by one who, when giving evidence on oath as a witness in a court of justice, before some competent authority of the same kind, gives evidence which he knows to be false. But in order to make the giving of false evidence a crime the evidence must be ma- terial—i.e. it must affect the decision of some question before the court. If the falsehood occurred as to some trivial or immaterial fact no crime is
committed. Moreover, it is necessary, in proving the crime, that at least two persons should be able to testify to the falsehood of the matter, so that there must be a majority of oaths on the matter; there being then two oaths to one. But this rule is satisfied though both witnesses do not testify to one point. The perjury must also have taken place before some court or tribunal which had power to administer the oath (see OATH). Though in some courts affirmations are allowed instead of oaths, yet the punishment for false affirmation is made precisely the same as for false swearing. The punishment for perjury was, before the Conquest, sometimes death or cutting out the tongue; perjury is now a misdemeanour, punishable by imprisonment with hard labour. The crime of Suborning of Perjury—i.e. the persuading or procuring a person to give false evidence—is also punishable as a distinct offence; if the false evidence is not given the crime is incitement. In many states of the American Union the crime of perjury by law, is further particularly defined by statute. The violation of an oath of office is not perjury; nor is a false affidavit to an account rendered to an administrator technically perjury, nor false evidence in depositions taken by consent by unauthorised persons.

Perkeniers. — MOLECCAS.

Petersburg, a town of the Prussian province of Brandenburg, 80 miles NW. of Berlin. Pop. 7825.

Perlitic Structure, in Petrography, is a structure seen in some vitreous rocks. These rocks seem as if made up of little pearly or enamel-like spheroids, each of which is subdivided into a number of concentric coats by curved cracks, running parallel to the surface, and the spheroids usually lie packed between rectilinear or curved fissures that traverse the rock in all directions. Perlitic is the name given to rocks showing this structure.

Perm, a town of Russia, on the Kama, by which it is 685 miles N.E. of Kazan. It is the chief seat of the extensive tracts of forest between European Russia and Siberia, and has a cathedral, tanneries, distilleries, flour-mills, and oil-works, and a government arsenal and cannon-foundry. Pop. 45,403. The government has an area of 123,314 sq. m. and a pop. (1897) of 3,963,298, and is constituted of 15 districts.

Permian System. In British this series of strata rests unconformably upon the Carboniferous rocks. It consists of the following groups:

Upper Red Sandstones, clay and silt (50 to 100 feet thick in east of England; west of Pennine chain, 600 feet thick).

Magnesian Limestone (500 to 600 feet): Zechstein of Germany.

Mort Slate (about 60 feet) = Kupferschiefer.

Lower Red and Mottled Sandstones, with conglomerates and breccias (3000 feet at Cumberland; in the east of England not over 250 feet) = Rothliegende of Germany.

The Lower Red Sandstones are greatly developed in Staffordshire, Cheshire, and Lancashire, and the Vale of Eden in Westmorland and Cumberland. Small areas also occur in the valleys of the Nith and Annan and in Ayrshire; and similar areas occur in the Scottish area the rocks extend to Arran in Ireland. The breccias met with in this group often contain erratics, and have the general aspect of glacial accumulations; and Sir A. Ramsay thought they probably indicated the occurrence of a glacial episode in the Permian period. In the Scottish area the rocks contain sheets of lava-form rocks and tuffs, associated with which are many small filled-up volcanic vents or necks. The most important member of the overlying groups is the Magnesian limestone, which is the chief repository of Permian fossils. Many of

its beds assume curious concretionary forms, as is well seen on the coast of Durham.

In Germany the Permian consists of an upper and lower group, the lower of which is often divided into the Zechstein and Kupferschiefer forming the upper, and the Rothliegende the lower group. Volcanic rocks are associated with the latter. The Kupferschiefer has long been famous for its ores of copper and other metals, and fossil fishes; while the Zechstein is associated with the representation of many undoubted Dinosaurs—the Zechstein and Kupferschiefer forming the upper, and the Rothliegende the lower group. Volcanic rocks are associated with the latter. The Kupferschiefer has long been famous for its ores of copper and other metals, and fossil fishes; while the Zechstein is associated with the representation of many undoubted Dinosaurs. In Russia the system occupies an area of more than 15,000 sq. m. between Moscow and the Urals. It is well developed in the government of Perm, from which it derives its name. While the German Dinosaurs presents the same general features as the Permian of Durham and the east of England, the Russian development resembles the Permians of the Midlands and north-west of England—limestone being quite a subordinate formation, and often wanting. Although there is considerable rockiness, especially the Permian and the Carboniferous, yet in some places, as at Antun in the heart of France, a conformable passage is traced from the coal-measures into the Permian. The same is the case in North America, where in the western part of that continent no hard and fast line can be drawn between the two systems—the Carboniferous gradually upwards into the Permian.

Life of the Period.—The Permian strata as a whole are not rich in fossils—the red sandstones which form so large a portion of the system being for the most part barren. A characteristic of the flora of the Carboniferous period that of the Permian is poor and meagre. But that poverty may be only apparent—the conditions for its preservation not having been so favourable as during Carboniferous times. But it is an important continuation of the Carboniferous flora. The most common plants are ferns—both herbaceous and arborescent—many of the genera being Carboniferous, while others, such as Callipteris, are not known as Carboniferous forms. Conifers were likewise numerous, especially the yew-like Walchia and the cone-bearing Ullmannia. Traces of what some suppose to have been eyecasts (Noggerathia) are met with in Permian strata. Finally, it may be noted that many characteristic Paleozoic types died out in Permian times, such as the Lepidodendrons, Sphenopsids, and Cartilaginous Fishes. The animal life of the period is somewhat better represented; but it too appears impoverished when contrasted with that which flourished in the preceding Carboniferous period. We note that rugose corals, so abundant in the older Paleozoic rocks, are very sparingly met with in Permian strata; even tabulate forms are feebly represented. Polyzoas are fairly numerous in the Magnesian limestone. Amongst brachiopods the more abundant types are survivivals from the Carboniferous, as Producta, Spirifer, Strophomena, and others. Lamellibranchs are somewhat more numerous than brachiopods, common forms being Schizodus, Bakevellia, Gervillia, &c. Gasteropods (Murchison, Pleurotomaria) are feebly represented, and the same is the case with the cephalopods (Nautilus, Orthoceras). It is worthy of note that the trilobites are represented by one form (Phillipsia)—the last appearance of that eminently Paleozoic order. Among the fishes the principal genera are Ophiomastus and Platyomastus. Amphibians are much rarer than in the preceding age; labyrinthodonts (Archegosaurus, Brachiosaurus, Pelsaurus). At this horizon true reptiles (Proterosaurus) make their earliest appearance.

In most parts of Europe where Permian strata are developed they rest unconformably on Carboniferous and other rocks, from which it is evident
that towards the close of Carboniferous times considerable earth-movements occurred in Europe, and resulted eventually in the isolation of certain areas, which thus became inland seas or salt lakes. In these latter molasse sandstones, dolomite limestones, rock-salt, and gypsum were accumulated, such as are the chief elements of the American "brine," or sultana, of the Riga, Berlin, and Hamburger, etc. Ourloner such inland seas covered large areas of what is now central England, and extended into southern Scotland and the north of Ireland. Similar large inland seas existed in middle and eastern Europe. The strata accumulated in such seas are often very beautiful, and the indications of shallow-water conditions, such as worm-tracks, sun-eracks, rain-pittings, and ripple-marks—evidences which indicates that the level of the lakes was often abnormally lowered during dry seasons, leaving wide tracts exposed over which crawled annelids, amphipods, and reptiles. Volcanic action was rife in Scotland and Germany, and it has been suggested that the abundant and well-preserved fish remains which occur in the Kupferschleifer may have been poisoned by the sudden influx of mineral springs connected with the volcanic districts, at intervals of time. Some of the inland seas may have had occasional connection with the open sea for longer or shorter periods, as, for example, during the formation of the thicker fossiliferous limestones. But, taken as a whole, the general character of the strata shows that they accumulated formed in inland seas. The climate of the period, so far as one can judge from the aspect of flora and fauna, was probably mild and genial. Nevertheless the occurrence of coarse breccias, with their scratched stones and erratics, in the strata of Permian and Triassic age, and the similar appearances met with in strata, which are believed to be of the same age, in India, Australia, and South Africa seem hard to explain without the agency of flowing ice.

Permissive Bill. See Local Option.

Permutations and Combinations. A combination, in Mathematics, is a selection of a number of objects from a given set of objects, without any regard to the order in which they are placed. The objects are called elements, and the possible selections are divided into classes, according to the number of elements in each. Let the given elements be the four letters $a, b, c, d$: the binary combinations, or selections of two, are $ab, ac, ad, bc, bd, cd$—six in all; the combinations of three are $abc$ only; the only one combination of four—viz. $abcd$. Permutation, again, has reference to the order of arrangement; thus, the two elements, $a$ and $b$, may stand $ab$ or $ba$, so that every combination of two gives two permutations; the three elements, $a, b$, and $c$, may stand $abc$, $acb$, $bac$, $bca$, $cab$, or $cba$, and combination of three thus affording six permutations. The combinations of any order with all their permutations are called the Variations. Formulas are given in works of algebra for calculating the number of permutations or combinations in any given case. Seven elements mark $1, 2, 3, 4, 5, 6, 7$, and two of these two are to be chosen; it is asked how many possible pairs of numbers there are, this is a question of the number of combinations of seven elements, two together, which is found as follows: $7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1 = 5040$. The theory of probabilities is founded on the laws of combination. Thus, in the case of drawing two tickets out of seven, since there are 21 possible pairs, the chance or probability of drawing any particular pair is $1 \div 21$, or $\frac{1}{21}$. In working out questions in 'combinations' advantage is often taken of the fact that, whatever number of elements be taken from a group to form a combination, the number left gives the same number of combinations; thus, the number of combinations of 10 elements three together, is the same as that of 10 elements seven together.

Pernambuco. See Recife, the busiest seaport of north Brazil, stands at the easternmost point of the coast, in $8^\circ 34'$ S. lat. It consists of three portions, connected by bridges—Recife (the 'roof') prosperous, compact, and beautiful, and extending along the winding streets, the chief seat of commerce, on a peninsula; San Antonio, a modern quarter, with straight, wide streets, on an island between the peninsula and the mainland; and Boa Vista, where are the merchants' villas, on the mainland. The principal buildings and public institutions embrace two arsenals, an observatory, the palace of the Bishop of Olinda (8 miles to the north), a law school, &c. The harbour is formed by a reef lying a quarter to half a mile from the coast, with an opening for vessels drawing 19 feet of water. Since 1880 some 2,000,000 tons of merchandise have been shipped, and the principal imports are sugar and cotton, with rum, hides, dyes, &c.; the principal exports are cottons and woollens, fish and meat, vegetables, minerals, wines, &c. The former fluctuates in value between $10,000,000 and $15,000,000, and the latter between $3,500,000 and $7,000,000. The nurseries, which supply the sugar and cotton crops; the imports average from one to two millions sterling. England, the United States, and France have the largest shares in this trade, England supplying about one-half of the imports, and between one-half and one-third of the exports.

Pernow (Ger. Perewin), a seaport of the Baltic Provinces of Russia, stands at the mouth of the river Pernow, at the northern extremity of the Gulf of Riga. 100 miles N. by E. of W. of Dorpat. Besides limed and barley, it ships large quantities of flax, principally to Great Britain. The total exports average £266,675 per annum (£323,000 for flax); the imports (herrings, coal, and chemical manure) only some £650,000. Pop. 12,918. The University of Dorpat was stationed here from 1699 to 1710.

Pérouse. See La Pérouse.

Perowen, John James Steuart, was born at Bideburn in Bengal, March 13, 1823, of a family of Huguenot origin. He had his education at Norwich grammar-school and at Corpus Christi College, Cambridge, carried off many prizes for theological knowledge and Hebrew, besides the Member's
Latin essay, graduated B.A. in 1845, and was elected Fellow of his college in 1849. He was afterwards examiner for the classical tripos, select preacher, Hulsean lecturer (1868), and Lady Margaret's preacher; professor in King's College, London; and from 1862 till 1872 vice-principal of St David's College, Lampeter. Later he was pre-lector in Theology and Fellow of Trinity College, Cambridge; preacher at the Chapel Royal, Whitehall; and canon residentiary of Llandaff from 1869 to 1878, when he was appointed Dean of Peterborough. Already, since 1875, he had been also Hulsean professor of Divinity at Cambridge, and an honorary chaplain to the Queen. In 1891 he succeeded Dr Philpott as Bishop of Worcester.

Dr Perowne is a sound Hebrew scholar, sat throughout in the Company for the revision of the Old Testament, and has been general editor of the admirable series of short commentaries forming "The Cambridge Bible for Schools." His principal work is his commentary on the Book of Psalms (2 vols. 1864-68), a masterpiece of exegetical science. Besides sermons and contributions to magazines, other works are his Hulsean Lectures on Immortality (1869), and Lampeter and Llandaff Sermons (1873).

**Perpendicular.** the name given to the style of Gothic architecture in England which succeeded the Decorated style. It prevailed from about the end of the 14th century to the middle of the 16th century, and was thus contemporaneous with the Flamboyant style in France. These styles have much in common, but they derive their names from the features peculiar to each. Thus, the Flamboyant (q.v.) is distinguished by the flowing lines of its triforium windows. The Perpendicular is remarkable for its stiff and rectilinear lines. The lines of the window-tracery are chiefly vertical, and the mullions are frequently crossed by transoms or horizontal bars. The mouldings are usually thin and hard. The same feeling pervades the other features of the style: the buttresses, piers, turrets, &c. are all drawn up and attenuated, and present in their shallow recesses and measure lines a great contrast to the deep shadows and bold mouldings of the earlier styles. The art of masonry was well under-stood during the Perpendicular period, and the vaulting was admirably built. Pan-tracery Vanishing (q.v.) belongs to this style. The depressed or four-centre arch is another of its peculiar features. In doorways the arched head is frequently enclosed in a square panel over the arch, with spandrels containing shields, quatrefoils, &c. Panelling was also much used, the walls being frequently covered entirely with it, as in Henry VII's Chapel at Westminster. There are many well-known buildings of this style. Most of the colleges at Oxford and Cambridge belong to it, and in almost every cathedral many chantry chapels have been erected. There are some specimens of it—e.g. William of Wykeham's nave at Winchester (q.v.). Open timber-rafts are very common in the Perpendicular style, and are amongst the peculiar and beautiful features of the architecture of England. The roof of Westminister Hall, built by Richard II., is the largest example ever erected.

**Perpetual Cure.** See Curate, Vicar.

**Perpetual Motion.** Formerly the attempts made to 'square the circle' led to an enormous waste of time and energy by repeated and unassailable methods, that the circular area cannot possibly be expressed in terms of the diameter or radius. It logically follows from the definition of a circle that it is a plane figure which does not admit of being squared. In the same way, to all who have understood the word force and motion, it follows from the definition of a machine that it does not admit of being perpetual, or selfmoved. Every machine is constructed to transmit motion or force. The machine, further, modifies the transmitted force, so as to overcome certain resistances, some useful and some prejudicial.' In every instance the motion of the machine is derived from without, and the energy so conveyed is to be at once referred to muscular action, or the weight of falling water, or a current of air, or the expansive force of steam, or some other natural power. Some such force is at once implied by the action of any machine, whether the motion is only commencing or has continued for an indefinite time. In an ordinary clock, for example, action is due to the muscular force expended in winding a spring or raising a weight; the sight of motion in wheels or levers compels us to believe that force has been exerted upon them, and that they are merely vehicles for transmitting it. The machine has gained so much motion and energy, but only at the expense of some exterior agent. The quantity of force in existence being fixed, no new stock can be created, and therefore a self-moving machine is absurd even in name. The practical engineer knows that the force of a steam-engine is exactly in proportion to the amount of coal burned per hour—the work depends on the consumption of heat. If the mechanical force produced is in excess, however small, of its equivalent (measured by the coal burned), then perpetual motion would be at last found, because then the engine would be generating force—i.e.
giving out more than was derived from the heat of the coals. This, of course, is impossible; it is from the inexhaustible stores of nature alone, such as fire, water, wind, chemical action, and electricity, that force is derived to give motion to any machine whatever. Instead of producing more force than it has received, and so laying up a stock of energy which might render it 'perpetual,' every machine must in its results show less energy than has been transmitted to it. Some of the machine's work is always spent on friction and the atmospheric resistance, so that it cannot give out all the force that was put in.

A 'simple pendulum swinging in an exhausted receiver, or a top spinning there, might illustrate the term Perpetual Motion, if friction could be avoided. Neither of these, however, could be called a perpetual machine. Give the top some work to do by putting it in gear, say, with a wheel or a crank, and speedily its motion slackens; which proves that, for a 'machine,' new force is constantly required from without, especially if anything more than mere motion is required. In the words of the French Academy (Histoire, 1775):

"Neglecting friction and resistance of air, a body whose motion has been given will retain it for ever, but only on condition that it does not act on other bodies; and the only perpetual motion possible, even on this hypothesis, would be useless for the purpose of the devisers. . . . Numerous mechanisms which might have been of great service have wasted (on this kind of research) their means, time, and talents."

The mere enumeration of all the chief attempts made in various countries to contrive a self-moving machine would be tedious. We shall only note some typical cases in each class. In one class of so called perpetual machines the essential part was a wheel revolving on a horizontal axis, with several movable weights so distributed round the rim as apparently to act more or less on one side than the other, and thus continue the revolution. One of these was by the ingenious Marquis of Worcester, and is described in his Century of Inventions as having been tried in the Tower before the king and court. On the same principle was Jackson's machine shown in fig. 1. In other attempts of this class, the sides of the wheels were divided symmetrically into cells with curved sides, each cell holding a ball which rolled about as the revolution took place, so that the balls should, by being further from the centre, act more on one side than on the other, as shown in fig. 2. A foreign instance, described in a letter to Newton as an unlooked for success, was that of Dr. Waverley, existing of a large wheel covered with canvas. When set in motion the speed increased till it reached a rate of twenty-five revolutions a minute; and when sealed up by the Elector of Cassel it was found at the end of two months to be moving as rapidly as ever. We must of course assume the existence of some imposition in this and more recent cases.

In another class of self-moving machines water or mercury became the prime motor, and was sometimes used in defiance of the most elementary laws of hydrostatics. One of these consisted essentially of a large vessel having a curved tube leading from the bottom up one side and bending over the brim. The inventor actually concluded that the great weight of the liquid in the vessel when full, or nearly so, must force the liquid in the tube up higher than the edge of the vessel, and thus cause a perpetual circulation.

Another class depended on magnetic action, such as Bishop Wilkins's inclined plane up which an iron ball was drawn in a groove by the attraction of a leadstone fixed at the top (fig. 3). Before reaching the leadstone the ball was ingeniously intended to fall through a hole in its path on to a curving incline beneath, and thus be conveyed by a second groove to the foot of the first inclined plane, in order to recommence its upward journey under exactly similar circumstances. The bishop overlooked the fact that the magnetic action would also tend to prevent a fall; but for that failure, he had come as near success as the laws of nature permit.

In Addeley's perpetual motion the wheel was surrounded by a set of magnets, projecting like teeth in a slanting direction, and having the S poles all towards the centre (fig. 4). Four larger fixed magnets were disposed outside the wheel, two of which at opposite points of the circumference presented their S poles to attract the revolving magnets, while half-way between them the other two presented their N poles to repel them. All the four magnets, however, acted against the inventor's purpose, as well as in the direction which he intended. In fact, if magnetic action or gravity could be temporarily nullified in a particular direction (as light is by interposing an opaque body) the problem of perpetual motion could immediately be solved.

Innumerable patents have been taken out for magnetic and electric machines, but in the principle of each some failure lurks, due to a misconception of the laws of force-transmission. A typical case is an electric machine driven by a gas-engine where the latter is heated by the decomposition of water by the electricity produced; just as if a steam-engine, for example, could be heated by the friction of certain bodies set in motion by itself.

Some intelligent and practical proposals have from time to time been made to utilise the rise and fall of tides as the motive power of machines. These, however, should not be classed as sometimes done, under those named 'perpetual,' since the supply of power is obviously derived from a natural source—the moon's attraction combined with the earth's daily rotation. A tide-mill, exactly as a water-mill or wind-mill, is entirely dependent on an outward supply of power, and can in no sense be termed self-moving or 'perpetual.' Ultimately, of course, all the forms of natural energy are to be referred to the sun, the
source of planetary force as well as life, whatever be their modifications. See H. Dircks, Perpetuum Mobile: Search for Self-motive Power (2d series, 1861-70).

Perpetuity, in English law, means an arrangement whereby property is tied up,—i.e., rendered inalienable—for all time or for a very long period. Testators and settlers have always been tempted to leave their effects forever entwined with the lands of the Catholic Church, with the Church of England, or with some other church or sect, with the King, or with the Crown, or with the public. In all such cases, if the property is to be divided among a family of Barnabas, or of Stearns, a trust will be created, to run, it will be observed, for a few years, and then will run forever. Such covenants, however, are not binding upon the courts, and are of no legal effect unless the conveyance itself is executed in the presence of some public officer, and is entered on the public records.

Perrin, a town in France, and a fortress of the first rank (dept. Pyrénées-Orientales), stands on the river Têt, 7 miles from the Mediterranean, 40 by rail S. of Narbonne, and 17 from the Spanish frontier. It commands the passes of the Eastern Pyrenees, and is defended on the south by a citadel, which overlooks the castle and the mountains of Roussillon, and by a detached fort. The streets are narrow and the houses of semi-Moorish construction, and show evidences of Spanish influence. The cathedral (begun in 1324), the Moorish-Gothic cloister-hall or bourse (1390), the town-house (1692), the building of the former university (1349-French Revolution), the palace of justice, and a college are the principal public buildings and institutions. Good red wine is made, sheep and silkworms are bred, vegetables and fruit grown, brandy distilled, cattle reared; and there is a good trade in wine, spirits, wool, cork-hoops, oil, cloth, and silk. As capital of the former county of Roussillon Perrin was in the hands of the kings of Aragon from 1172 to its capture by France in 1473; it was restored to Spain in 1493; but rebellions from 1563 to 1642, and other disturbances, have possessed it ever since. Pop. (1891) 31,432.

Perranzabuloe ('Perran in the sands'), a Cornish coast parish, 10 miles N. by W. of Truro. The rude little stone oratory (25 by 12 feet) of St Piran, who was sent to Cornwall by St Patrick in the 5th century, had been buried in the sands for a thousand years, and was discovered in 1642. This is probably the earliest ecclesiastical structure in England. Perran Round is a circular enclosure, with seven rows of seats that could seat 2000, in which miracle plays were performed of old. See works by Haslam (1844) and Trelawny (8th ed. 1884).

Perrault, Charles, immortal as the author of 'Puss-in-Boots,' 'Cinderella,' and 'Bluebeard,' was born at Paris, January 12, 1628, the youngest of an advocate's four sons. He was sent at nine to the College des Quatre-Nations for three years, and was then sent to the Jesuit college, and thence to the University of Orleans, where he studied law, and took his degree. He was admitted to the Bar at Orleans in 1651, but soon tired of the humdrum routine of the profession, and filled from 1654 till 1664 an ease post under his brother, the Receiver-general of Paris, and in 1669 was appointed to be a kind of secretary or assistant to Colbert in matters of architecture and art generally, and for twenty years enjoyed a salary, if not his master's friendship throughout, while by his influence he was admitted to the Academy in 1671. His poem, 'Le Siècle de Louis XIV.' (1695), became so popular that it was repeated, and Boileau's angry criticisms thereon, opened up the famous and foolish dispute about the relative merits of the ancients and moderns; to the modern cause Perrault contributed his ambitious but poorly argued Parallèles des Anciens et Modernes (4 vols. 1688-96). The same quarrel inspired his Éloges des Hommes Illustres du Siècle de Louis XIV. (2 vols. folio, 1705; new editions, 1800), a work which was thought to be a disgrace to the Academy.

Perth, a city in Scotland, on the River Tay, 11 miles N.W. of Dundee, and 90 miles S.S.W. of Edinburgh. It is the market for a large district, and has manufactures of cotton, woollen and linen goods, machinery, &c. Pop. (1871) 21,093; (1901) 31,555.

Perry, an agreeable beverage made from fermenting the juice of the peach, and it is probably the earliest ecclesiastical structure in England. Perran Round is a circular enclosure, with seven rows of seats that could seat 2000, in which miracle plays were performed of old. See works by Haslam (1844) and Trelawny (8th ed. 1884).

Perrault, Charles, immortal as the author of 'Puss-in-Boots,' 'Cinderella,' and 'Bluebeard,' was born at Paris, January 12, 1628, the youngest of an advocate's four sons. He was sent at nine to the College des Quatre-Nations for three years, and was then sent to the Jesuit college, and thence to the University of Orleans, where he studied law, and took his degree. He was admitted to the Bar at Orleans in 1651, but soon tired of the humdrum routine of the profession, and filled from 1654 till 1664 an ease post under his brother, the Receiver-general of Paris, and in 1669 was appointed to be a kind of secretary or assistant to Colbert in matters of architecture and art generally, and for twenty years enjoyed a salary, if not his master's friendship throughout, while by his influence he was admitted to the Academy in 1671. His poem, 'Le Siècle de Louis XIV.' (1695), became so popular that it was repeated, and Boileau's angry criticisms thereon, opened up the famous and foolish dispute about the relative merits of the ancients and moderns; to the modern cause Perrault contributed his ambitious but poorly argued Parallèles des Anciens et Modernes (4 vols. 1688-96). The same quarrel inspired his Éloges des Hommes Illustres du Siècle de Louis XIV. (2 vols. folio, 1705; new editions, 1800), a work which was thought to be a disgrace to the Academy.

Perthshire, a county of Scotland, lying on the southern slopes of the Grampian Mountains, and extending from the Tweed in the east to the Firth of Clyde in the west, and from the Clyde to the Dee. It is divided into two districts, Northern and Southern, and in the southern, there are the famous Huntingdon Forests, and also a great deal of forest land. The county is divided into three districts, Northern, Southern, and Western, and in the southern, there are the famous Huntingdon Forests, and also a great deal of forest land. PERRY

diet-drink of those districts. It contains from 3 to 9 per cent. of alcohol. See CIDER.

Perry, Oliver Hazard, an American naval officer, born at South Kingston, Rhode Island, 23d August 1785, is famous for his defeat of a British force on Lake Erie in 1813. Perry, who had nine vessels, with 54 guns and 492 officers and men, fought six vessels, with 63 guns and 492 officers and men, and being four-fifths of the crew of his flagship, and finally won a complete victory, which he announced in the brief dispatch: 'We have met the enemy, and they are ours—two ships, two brigs, one sloop, and one schooner.' Perry died yellow fever, 23d August 1819, and was buried at Newport, Rhode Island, where there is a bronze statue (1885). See Life by A. S. Mackenzie (2 vols. New York, 1843), and In Feni- more Cooper's Lives of Distinguished American Naval Officers (1846).

Perrysville, a village of Kentucky, about 40 miles S.W. of Lexington, was the scene of a hard-fought battle between the Union and Confederate armies of Buell and Bragg, 8th October 1862.

Persecution. The principles that underlie the persecution of obnoxious opinions, as opposed to the principles of toleration, are regarded by those who persecute as essentially similar to those that arm justices against the criminal. Persecution on religious or political grounds has been especially common. The persecutions of the early Christians by the Roman emperors (see CHURCH HISTORY) have been usually, though artificially, counted as ten, viz. under Nero, 61 A.D.: Domitian, 95; Trajan, 107; Hadrian, 119; Marcus Aurelius, 165; Septi- minia Severus, 202; Maximinus, 233; Decius, 249; Valerianus, 257; Diocletian, 303. Some of the best of the emperors were thus the most strenuous persecutors of the Christians. The persecution seemed in many cases to fan the zeal of the victims and survivors; in Tertullian's words, the blood of the martyrs was the seed of the church. Cathari and Albigenses were practically persecuted out of existence by the Dominicians and the Inquisition; and the measures adopted to suppress the Reformations were triumphant in Bohemia and Spain. Roman Catholicism was thus complicated with politics (see BARTHOLOMEW, ST.; the Dragonades (q. v.) were part of a deliberate attempt to crush out Protestantism. The name persecution is used in England specially for the sufferings inflicted by Catholics on Protestants and by Protestants on Catholics in Mary's and Elizabeth's reigns; in Scotland also on the measures used against the Covenanters and other rebellants in the 17th century. The oppressive legislation against Independents in Charles II.'s reign may also be classed under this head; and Massachusetts and most of the Puritan colonies passed several repressive measures against the Quakers. The persecutions carried on in the Netherlands by the Spanish authorities (see HOLLAND) were especially persistent. They comprised fine, imprisonment, whipping, the gallow, strangling, stranguing and burning, burning alive, burning alive; and their continuance goaded the people into a great national revolt. It deserves to be noted that the strenuous denunciation by Vol- talgo of the most inhuman of the inhuman Caesars (q. v.) family led to a new chapter in the history of toleration. Furious persecutions extinguished Catholicism from Japan in the middle of the 17th century, and Corea in the middle of the 19th. The Orthodox Eastern Church has in Russia had the assistance of the state in repressing the Raskolnik sectaries. Luther and Melancthon were more persecuted by the princely Catholic authorities than the Catholic authorities. A notable case of the persecution of a Pro- testant by Protestants is that of Servetus (q. v.; see also CALVIN). In this case Calvin had the sympathetic support of many foreign Protestant churches and the leaders of the Reformed system established in Geneva by Calvin so confounded errors, sins, and crimes as to turn the administration of justice largely into a persecuting organisation; in three years there were fifty-eight sentences of death, and over eight thousand imprisonments for the crime of blasphemy (see Hug and Stonesfield, Switzerland, 1891). The old Scottish discipline of the kirk-session was regarded as persecuting in spirit long ere it ceased to be rigorously applied. The persecutions of the Jews were especially persistent and especially unsuccessful, and have recurred in recent years in Russia, Poland, and the Bosphorus. From other causes as persecution come much other bloodshed and strife, war and devastation, social oppression, and personal suffering. Metaphysical principles formed the watchwords of political as well as of ecclesiastical parties. 'These evils mostly came from that wicked and in- numerably dangerous fact in Christian history—the interference of the state, which gave the decrees of the councils that sanction which elevated the resolu- tions of the majority upon the deepest subjects of human speculation to the factitious rank of laws which must be accepted on pain of forfeiture, banish- ment, or death' (Hatch, Tihberr Lectures, 1888).

Persephone. See PROSERPINE.

Persep'olis ('Persian City'), the Greek translation of the lost name (Parsu-Kurta) of the capital of ancient Persia, was situated to the east of the river Medus (Polwar—i.e. Murghab), about 34 miles from the Caspian Sea. The ancient name of Persepolis is now given to Shiraz, in the plain of Mervshah, about 35 miles to the north-east of Shiraz, on the road to Ispahan. A series of most remarkable ruins is all that now remains of that city, with which, according to ancient writers, 'no other city could be compared either in beauty or in wealth, and which was generally designated 'The Glory of the East.' Darius Hystaspes, Xerxes, Artaxerxes, and other Achemenides each in his turn contributed towards its grandeur. Alexander the Great in his march of conquest said he had not seen Persopolis completely; but this must probably only be understood to apply to some of the chief palaces. It may also be presumed that after the fall of the Achemenides the extension of the original town (afterwards known as Isfakh), on which it was built, on the ruins of Persepolis and the temples used as royal treasuries up to the time of Epiphanes, gradually fell into decay. The situation of these structures, overlooking the vast luxurious plain of Mervshah, is described in terms of rapturous enthusiasm by every traveller from Charlemagne to Pococke. The most day distinguishable in the vast ruins existing on the spot. First, the Chehel-Minâr (Forty Pillars),
with the Mountain of the Tombs (Rachmed), also called Takht-i-Jamshid or the throne of Jamshid, after a fabulous king, the reputed founder of Persepolis. The next in order is Naqsh-i-Rustam, to the north-west, with its tombs; and the last, the building called the Haram of Jamshid. The most important is the first group, situated on a vast terrace of cyclopean masonry at the foot of a lofty block, and in many cases of this terrace is about 1500 feet north by south and about 800 east by west, and it was, according to Diodorus Siculus, once surrounded by a triple wall of 16, 32, and 60 cubits respectively in height. The whole intends to divide it into three terraces —the lowest towards the south; the central being 800 feet square and rising 45 feet above the plain, and the third, the northern, about 550 feet long and 35 feet high. No traces of structures are to be found on the lowest platform; on the northern, only the so-called 'Propylaia of Xerxes'; but the central platform seems to have been occupied by the foremost structures, which again, however, do not all appear to have stood on the same level.

There are distinguished here the so-called 'Great Hall of Xerxes' (called Chehel-Minar by way of eminence), the Palace of Xerxes, and the Palace of Darius. The stone used for the buildings is dark grey marble, cut into gigantic square blocks, and in many cases exquisitely polished. The ascent from the plain to the great northern platform is formed by two double flights, the steps of which are nearly 22 feet wide, 32 inches high, and 15 inches in the tread, so that many travellers have been able to ascend them on horseback. What are called the Propylaia of Xerxes on this platform are two massive stone-ways, which probably formed an entrance-gateway for foot-passengers, paved with gigantic slabs of polished marble. Portals still standing bear figures of animals 15 feet high, closely resembling the Assyrian bulls of Nineveh. The building itself, conjectured to have been a hall 82 feet square, is, according to the cuneiform inscriptions still extant, the work of Xerxes.

An expanse of 162 feet divides this platform from the central one, which still bears many of those columns of the Hall of Xerxes from which the ruins have taken their name. The staircase leading up to the Chehel-Minar or Forty Pillars is, if possible, still more magnificent than the first; and the walls are more superbly decorated with sculptures, representing colossal warriors with spears, gigantic bulls, combatants with wild beasts, processions, and the like; while broken capitals, shafts, pillars, and countless fragments of building- stones are to be found. The whole vast space of this platform, 350 feet from north to south and 380 from east to west. The Great Hall of Xerxes, perhaps the largest and most magnificent structure the world has ever seen, is composed to have been a rectangle of about 300 to 350 feet, and to have consequently covered 105,000 square feet or 24 acres. The pillars were arranged in four divisions, consisting of a centre group six deep every way, and an advance body of twelve in two ranks, the same number flanking the centre. Fifteen columns are all that now remain of the number. Their form is very beautiful. Their height is 60 feet, the circumference of the shaft 16, the length from the capital to the torus 44 feet. The shaft is finely fluted in fifty-two divisions; at its lower extremity begin a cincture and a torus, the first 2 inches in depth and the latter 1 foot, from whence devolves the pedestal, shaped like the cup and leaves of the pendent lotus, the capitals having been surmounted by the double semi-bull. Behind the Hall of Xerxes was the so-called Hall of Hundred Columns, to the south of which are indications of another structure, which Ferguson terms the Central Edifice. Next along the west stood the Palace of Darius, and to the south the Palace of Xerxes, measuring about 850 feet square, similarly decorated and of similar grand proportions.

For a more minute description see the travels of Niebuhr, Ker Porter, Rich, &c.; Ferguson's Palace of Nineveh and Persepolis Restored, Vaux's Nineveh and Persepolis, Rawlinson's Five Great Monuments, Madame Dacier's La Perse et La Susiane, M. Dieu-

![Great Staircase to Northern Platform, and Propylaia of Xerxes; Great Hall of Xerxes and Palace of Darius in the distance.](image-url)
Perseverance of Saints, a doctrine necessarily resulting from the most essential part of the Calvinistic system, and therefore held by almost all the confessors of that system. It is advocated not only by arguments from other doctrines, as those of election, atonement, the intercession and mediatorial dominion of Christ, imputed righteousness, and regeneration, but also from many texts of Scripture, as those which declare eternal life to be always connected with believing, and those which encourage the believer to depend on the faithfulness, love, and omnipotence of God. To an objection very commonly urged against it, that it tends to make men careless concerning virtue and holiness, its answer is that the objection is valid only against a doctrine very different from theirs, the true doctrine of Perseverance of Saints being one of perseverance in holiness, and giving no encouragement to a confidence of final salvation which is not connected with a present and even an increasing holiness.

Persia, a pleasant, old-fashioned market-town of Worcestershire, in a great fruit-growing district, on the Avon, 9 miles S.E. of Worcester. Holy Cross, the church of a mitred Benedictine abbey, originally founded in 689, is but a fragment—chancel, south transept, and central tower, mainly decorated in style, but with Norman and Early English features. It was restored by Scott, in 1863-65. Pershore has manufactures of stockings and agricultural implements. Pop. (1831) 2717; (1841) 2883; (1851) 2708. See Styles's History of Pershore Abbey Church (1839).

Persis, called by the natives Iran (see Aryan Race), the most extensive and powerful native kingdom of western Asia, is bounded on the N by the Transcaucasian provinces of Russia, the Caspian Sea, and the Transcaucasian provinces of Russia; on the E. by the Transcaucasian provinces of Russia, Afghanistan, and Persia; on the S. by the Persian Gulf and the Persian Gulf; and on the W. by Asiatic Turkey. It extends 900 miles from east to west and 700 miles from north to south, and has an area of about 638,000 sq. m. It consists for the most part of a great tableland or elevated plateau, which in the centre and on the east side is a dead level, about 10 feet above the sea, and on the north, west, and south is covered with mountain-chains. The provinces of Azerbaijan, Mazaranderan, Tiflis, Kurdistan, Laristan, and Fars are the most mountainous. From the southern boundary of Azerbaijan the majestic range of the Elburz runs eastward, following the line of the Caspian coast at a distance varying from 12 to 90 miles. On reaching Astrabad the mountains sink into ridges of lower elevation, one of which joins the Pamirians in Afghanistan. A little country lies north of this line; it terminates in the Damansur Koh chain, which sinks abruptly to the low plain of Turkistan. South and east of Azerbaijan a broad mountain-plain traverses Persia from north-west to south-east, the chains and valleys of which are covered by a belt of hills which consists lying in the same direction. To this region belong the mountains running from Hamadan to Shus, some of the peaks of which are clad with perpetual snow, and the Zagros Mountains and Dushlu Koh on the western frontier. The Persian mountains are mostly primitive; granite, porphyry, felspar, and mountain-limestone enter largely into their composition. They also exhibit indications of volcanic action. Damavand, a conical peak 18,600 feet in height, the highest summit connected with the Elburz range (or ranges), being an extinct volcano; and earthquakes occasionally occur. The Persian plateau, which lies in an angle formed between these mountains, is intersected by many subsidiary ranges and groups of mountains, and spreads east-west for 200 miles. The general elevation ranging from 2000 to 5000 feet is too low, level, the lowest part being the Great Salt Desert in the south-west of Khorasan, which has 2000 feet of elevation above the sea; while the average elevation of the whole plateau above the sea is about 3700 feet. See ASIA.

A great part of Khorasan, the north half of Kerman, the east of Irak-Ajeni, which form the great central plain, and detached portions of all the other provinces, with the exception of those on the Caspian Sea, forming more than three-fourths of the surface of Persia, and to say, are uncultivated wastes, to a small extent. A narrow strip of low and level country extends along the shores of the Persian Gulf and the Strait ofOrmuz. It consists of a succession of bare plains, occasionally interrupted by a plantation of palms near the seacoast rivulets which traverse it. It is called Dushtistan, or by the generic name, applied to many other localities, of Gurmail—i.e. the warm region, in opposition to the mountainous districts, called Sarkand, or the cold country.

Although so much of Persia is desert, some parts of the country are of exceeding fertility and beauty; the irrigated valleys, some of them 100 miles in length, between the various ranges of the Kerman Mountains abound with the rarest and most valuable vegetable productions. Great portions of the provinces of Fars, Khuizstan, Ardekan, and Azerbaijan have been lavishly endowed by nature with the most luxuriant vegetation; while the provinces of Ghilan and Mazanderan, which lie between the Elburz and the Caspian Sea, and the southern slopes of the Elburz are as beautiful as wood, water, and a moderately hot climate can make them—the mountains being clothed with trees and shrubs, and the plain, 300 miles long and 100 miles wide, studded with mulberry plantations, rice-fields, vineyards, orchards, orange grounds, and sugar and cotton plantations.

River and Lakes.—Persia has hardly one river that can be termed navigable, though some of them are several hundred miles in length, and of great width and volume of water. The Karun (q.v.) was opened to foreign steam-navigation from its mouth to Ahwaz (where there is a series of rapids) in 1890. The rivers which flow to the sea receive in the latter part of their course few tributaries, and from the only a narrow strip of land on each side of them, except when their waters are applied, by means of canals or other works, to the artificial irrigation of the soil. Most of the monuments of the architectural skill
and laborious industry of the ancient Persians in this department are now ruined. As a natural consequence of the nature and situation of its surface, Persia abounds with saline lakes, and there are nearly thirty of them having no visible outlets. The chief lake is Lake Urmiah (q.v.), in Azerbaijan. Lake Bakhtegan, in the east of Fars, the receptacle for the drainage of the northern half of that province, is about 60 English miles in length by 9 in breadth. Lake Shiraz is much smaller. Part of Lake Zirreh is included in the frontier of Persia.

Climate and Products.—The climate is necessarily very varied. What the younger Cyrus is reported to have said to Xenophon regarding the climate, 'that people perish with cold at one extremity of the country, while they are suffocated with heat at the other,' is literally true. Persia may be considered to possess three climates—that of the southern Dashtistan, of the elevated plateau, and of the Caspian provinces. In the Dashtistan the autumnal heats are excessive, those of summer more tolerable, while in winter and spring the climate is delightful. On the plateau the climate of Fars is temperate. About Isphahan the winters and summers are equally mild, and the regularity of the seasons appears remarkable to a stranger. To the north and northwest of this the winters are severe. The desert region of the centre and east, and the country on its border, endure most oppressive heat during summer and piercing cold in winter. The Caspian provinces, from their general depression below the sea-level, are exposed to a degree of heat in summer almost equal to that of the West Indies, and their winters are mild. Rains, however, are frequent and heavy, and many tracts of low country are marshy and extremely unhealthy. Except in the Caspian provinces, the atmosphere of Persia is remarkable above that of all other countries for its dryness and purity.

The cultivated portions of Persia, when supplied with moisture, are very fertile, producing an immense variety of crops. The chief cultivated products are wheat (the best in the world), barley, and other cereals, cotton, sugar and rice (in Mazanderan), and tabak or tobacco for the narghil or water pipe. The vine flourishes in several provinces, and the wines of Shiraz are celebrated in eastern poetry. Mulberries are also largely cultivated, and silk is one of the most important products of the kingdom. Owing, however, to the selfish and immense demands of the Persian government to procure healthy grain from abroad, the silk cultivation has of late years greatly diminished.

The forests of the Elburz abound with wild animals, as wolves, tigers, jackals, bears, buffaloes, foxes, and the Caspian cat. Leopards abound in Mazanderan, and lions in parts of Fars and Kurdistan. Among domestic animals the horse, the ass, and the camel hold the first place. The horses have always been celebrated as the finest in the East. They are larger and more handsome, but less fleet than the Arabian horses. The Caspian rivers abound with fish, especially sturgeon, great quantities of which are cured and exported to Russia. The mineral products of Persia are insignificant, with the sole exception of salt. Iron is abundant in Azerbaijan, but is not worked; copper occurs in considerable quantity in the mountains of Mazanderan and Kerman; and lead, antimony, sulphur, and naphtha also abound. Long before in length by 9 in breadth. Lake Shiraz is much smaller. Part of Lake Zirreh is included in the frontier of Persia.

Isphahan, looking south.
cathedral. Including those who have joined the Roman Catholic and Protestant churches, the whole number of Christians hardly exceed 50,000. The Jews number 15,000.

We have no certain information concerning the population of Persia. There can be no doubt that in antiquity, and even during the middle ages, while the irrigation works still fertilised great tracts of land, it protected a great population. In the 17th century the French traveller, Chardin, thought 40 millions not too high a figure. Recent travellers, however, reduced these sums to numbers varying from 15 to 8 millions. Much surprise was accordingly expressed when in 1868 Sir Ronald Tirwhitte remarked that the entire population did not exceed 6 millions, and was probably not over 4 millions. His estimate has since been generally accepted as the most trustworthy we have, although the official estimate in 1881 was 7,653,000. He divides the total roughly into a million inhabitants of cities, 1,750,000 nomads, and 1,700,000 peasants and villagers; and the following are his estimates of the population of the chief cities: Tabriz, 110,000; Teheran, 85,000; Meshed, 70,000; Isphahan, 60,000; Yezd, 40,000; Kerman, 30,000; Kerman-shahr, 30,000; and Teheran, 200,000. The latter has largely increased since this estimate was made, and in 1891 was said to have 210,000 inhabitants. There can be no doubt that the population of Persia has been long diminishing, a fact attributable to misrule and extortion, neglect of the great irrigation works, and the frequent occurrence of famines in a dry country where cultivation depends on an artificial supply of water.

The roads are utterly neglected. The houses, those of the wealthiest people not excepted, appear contemptible, being generally built of earth and mud, and even in the towns, with little attention to uniformity or order. They scarcely ever exceed one story in height, and they are surrounded by high blank walls. The public buildings, such as mosques, colleges, and caravanserais, are of similar appearance to the ordinary houses of common materials. The interiors, however, of the houses of the rich are sometimes perfect paradises of luxury and elegance. The miserable look of the towns is, moreover, greatly redeemed by the beauty of the gardens which surround them and their inlets.

Manufacture and Trade.—The trade of Persia is comparatively of little importance. The silk used to be the great staple, and is produced in almost every province, but chiefly in Gilan, Koushan, and Yezd. The repeated failure of the crop has, however, interfered very seriously with this branch of industry. Cotton and woollen fabrics, shawls, carpets, and felt are largely manufactured for use and export in different parts of the country. Trade is carried on by caravans with the interior of Asia and the chief towns of Persia. These caravans exchange the products of Persia for cloths, printed calicoes, shifting, copper sheets, hardware, glasses, and porcelain, tea, coffee, sugar, candles, paraffin oil, hiccider matches, and fancy goods. The principal trade centres are Tabriz, Teheran, Isphahan, and Bishapour. European goods are brought to Tabriz by Constantinople and Trebizond, and to Teheran partly by Tabriz, partly by the Caspian, and partly by Bishapour; while to Isphahan they are brought almost exclusively by Bishapour. In recent times the communication between Persia and foreign countries has been greatly increased by way of the Caspian owing to the development of the cuprous petroleum wells at Baku. By means of the cheap fuel thus obtained the Russian commercial fleet on the Caspian has increased fourfold, and railways have been made from Batum on the Black Sea to Baku on the Caspian, and from the eastern coast of the Caspian to Akhbad, Bokhara, and Samarkand. On the former sea there is a considerable traffic of schooners sailing weekly from Baku to Tabriz, and vessels sail weekly from Astrahkán and bi-weekly from Baku with merchandise for the Persian coast, touching at Enzeli, Mashhadisar, and Ashlurada. In the Persian Gulf the British India Steam-navigation Company has a regular line of five steamers running weekly from Bombay to Basra, and touching at Beuder-Abbas and Bushire. Port nighty steamers were started in 1889 by an English firm on the Kurn to paint between Mohamman role and Alwaz in virtue of the concession of free navigation granted by the Shah in 1888. In 1890 Mr. Cunard stated that in the north-west, north, and north-east districts a decided Russian superiority in trade was met and in parts disputed by British and Indian competition; in the south and west British ascendency is established and is being increased. The exports consist of wheat, rice, wine, raisins, almonds and nuts, olive-oil, tobacco, drugs, gums, resins, manna, opium, colouring matters, boxwood, walnut-wood, silk, wool, carpets, skins and furs, wax, pearls, turquoises, sulphur, napthia, salt; the chief imports are cotton goods from Britain, and broadcloths, jewellie, vogue, cutlery, wines, quinine, arms, metal wares, &c. The whole foreign trade of Persia has been estimated roughly at—imports, £3,300,000; exports, £3,000,000. The imports of British produce into the three ports of Bushire, Lingal, and Bender-Abbas amounted in 1885 to over £570,000, not including Indian cotton. Exports to Britain thence were worth £175,000. In 1889-95 the average value of imports from Russia was £87,000, and of exports to Russia £1,486,000. The export of Persian carpets—of which there are many varieties of texture—amounts to £150,000 a year. Many projects of railways have been forwarded since 1845, but up to 1850 only one of them had been carried out—viz. from Teheran to Shah Abul Amin, a place of pilgrimage distant only 6 miles. Tramways were laid down in Teheran, and an imperial bank established with branches in the other large towns, in 1889.

Government, Taxation, Education, &c.—The government of Persia is a pure despotism, limited only by the power and influence of the Mohammandan mollahs or priests, domestic intrigues, dread of foreign influence, and a love of private immunities and privileges. The principal source of revenue is customs derived from the foreign trade. The first minis is the principal chief against unjust government on the part of the monarch, while the latter three operate as powerful restraints on his ministers. The monarch, who has the title of 'Shah' and 'Pahlisbath,' possess absolute authority over the lives and property of his subjects. He disposes, the governors of provinces and districts, possess similar authority over those under them; their actions are, however, liable to revision by the Shah, who may summarily inflict any punishment upon them for real or alleged misgovernment, and an occasional investigation of the customary agricultural classes is almost a necessity of such a form of government. The central government consists of a ministry, nominally modelled on the cabinets of European states. Usually, however, the power falls actually, if not nominally, into the hands of a vizir. The Shah, nevertheless, is in reality his own prime minister, and even trivial matters are submitted for his personal decision. The principal ministers are those for the interior (practically the head of the government), for Foreign Affairs, for Finance, for War, for Telegraphs, &c. The President of the Council, who is at the same time postmaster-general and general secretary of state. The law both in civil and criminal cases is administered by the governors, who not infrequently refer
points of law, which is based upon the Koran and its commentaries, to mollusks and muskateedhs. The punishments commonly inflicted are fines, flogging (the bastinado), and death, either by decapitation, stabbing, or torture. The principal Hakim or government of provinces are chosen for the most part from among the members of the royal family. As a rule life and property are much more secure than is generally supposed. The revenue is derived from (1) a tax on the gross produce of land—25 per cent. may be taken in the case of impostums; (2) duties on cattle and flocks—in case of goats, sheep, and cows, 8 per cent. on value of wool and butter yielded; (3) customs dues; and (4) duties on provisions brought to market. It will thus be seen that the direct taxation falls almost exclusively on the land and its cultivators. In theory these are the taxes authorised by the government, but in practice a frightful system of bribery and extortion prevails. The wealthy and influential escape the rapacity of the provincial governors, but as much as possible is taken from the hard-working peasants. It is believed that the irregular exactions amount to a sum equal to the illegal assessments, and that not a penny of the money so extorted is applied to public purposes. The annual revenue in 1890-97 may be stated at from £1,000,000 to £1,775,000.

Elementary education is very generally diffused among the Persians. There are several state colleges where students are instructed in religion and Persian and Arabic literature. Among a considerable section of the upper classes it is asserted that the Mohammedan religion is losing its hold, and that infidelity is widely prevalent.

Politic Division, etc.—From the earliest times down to the present century Persia was divided into seven or eight great divisions; but about the time when it was attempted to introduce European civilization into the country, and discipline into the army, the country was divided into twenty-five provinces. There are many interesting ruins of ancient, populous, and celebrated cities in Persia—e.g. Persepolis (q.v.), and Isakhir, Rhages or Rê, Shahpur, Tis, Merv, Shusban, Hamadan, etc.

As a standing army, according to the recent army laws, consists of 200,000 men, but the majority of these exist only on paper. The regular army is really composed of about 30,000 infantry and 1000 artillery, while there are about 10,000 irregular cavalry, a few thousand irregular infantry, and the gunners. The officers in the Persian army are for the most part ignorant and inefficient, but the soldiers are obedient, sober, intelligent, and capable of enduring great fatigue. The irregular cavalry, which forms the bravest portion of the Persian army, is equal to the Cossacks in the Russian army, and much superior to the Turkish Bashi-Bazouks.

History.—According to the Shah Nameh of Firdausi, the history of Persia begins some thousands of years before the Christian era. Little less than 2000 years ago extracting the grains of historical truth that may be contained in the innumerable fables that constitute the native Persian annals, and as yet we must rest contented with the accounts derived from Greek writers. The north-western part of Iran, anciently called Media (q.v.), was, at the beginning of the Christian era, included in the Assyrian empire, but the Medes revolted, and in 704 B.C., under Dejobes, established an empire which sublimed both that of Assyria and their own kindred tribes of Persis. About 557 the Persians under Cyrus (q.v.—the Kai-Khusru of the Persians), renowned for his skill in forming kings, the Medes (who from this time became amalgamated with them), and established a mighty empire, which included, besides Persia, as far as the Oxus and Indus, Asia Minor, Syria, Palestine, and Mesopotamia. His son, Cambyses, a most ferocious and bloodthirsty tyrant (529-522), subdued Tyre, Cyprus, and Egypt. After the brief rule of the usurper Smerdis (522-521), Darius I. (q.v., surnamed Hystaspes—the Gryphus of the Greeks—521-485) mounted the throne. He was a politic and energetic prince, and succeeded in firmly establishing his dynasty, and adding Thrace and Macedonia to his empire; but his two attempts to subdue Greece were completely foiled, the first by the Thracians, the second by the Greeks at Marathon (490). His son, Xerxes I. (485-465), renewed the attempt to subdue the Greek states, and, though at first successful, was compelled by the defeats of Salamis and Plataea to limit himself to a defensive warfare, which exhausted the v.; sources of his kingdom. His son, Artaxerxes I. (465-425), surnamed Longimanus (the Bahan of the Persians, better known as Arshadir Deradjast), was a valiant prince, but he was unable to stay the decadence of Persia, which had now commenced. He, however, crushed a formidable rebellion in Egypt, though his wars with the Greeks and Ionians were unsuccessful. The empire now became a prey to intestine dissensions, which continued during the reigns of his successors, Xerxes II., Sogdianus, Darius II., Artaxerxes II., and Artaxerxes III. (q.v.). Darius III. Costerzhes (the Great) of this dynasty was compelled to yield his throne to Alexander the Great (known as Iskander or Senunder by the Persians), who reconquered all the former provinces of Persia, and founded a vast empire, which, at his death, in 324, was divided into four parts, Persia along with Syria falling to the share of the Seleucids, and its old dependency, Egypt, to the Ptolemies.

The Seleucids soon lost Bactria (now Balkh), which became independent under a series of Greek sovereigns, and about 246 Parthia Persia (now Northern Khorassan) also rebelled under Arsaces I., who founded the dynasty of the Arsacids, under whom the greater part of Persia was wrested from the Greeks, and maintained against both the Greeks and Romans. The Persian empire, including its provinces, which mainly included a great part of India, was overthrown by an influx of nomad tribes from Turkestan (160-140); and these invaders having been driven out by the Parthians, Bactria was added to their empire (188). But the dynasty of the Arsacids, which maintained itself for four hundred and fifty years, was brought to an end by a Persian named Ardashir Babegan, who managed to gain possession of Fars, Kerman, and nearly the whole of Irak, before Arham, the Parthian king, took the field against him. At last a great battle was fought (521 A.D.) on the plain of Hormuz, in which the Persians were completely victorious. Babegan was now hailed as Ardashir (Artaxerxes), king of Persia, and 'Shahân Shah,' or king of kings, his dynasty being named Sassanid from his grand-father Sassan. To Sassan the Sassanids owed their rise to a height of power and prosperity such as it never before attained, and more than once imperilled the existence of the eastern empire. The most notable kings of the dynasty were Shahpur I. or Sapor (240-273), who crushed the Babilon and captured the Serurian captive at Edessa; his grandson, Shahpur II., who also maintained an equal conflict with the Romans; and Chosroes 1. and 2. (q.v.), the latter of whom was ultimately crushed by Heraclius (q.v.) in 628.

The last Sassanid king, Yazdegerd (Yazdjlour), was driven from the throne, after a great battle at Nahavend (639) by the Arabs, who now began to extend their dominion in all directions; and from this period may be dated the gradual
change of character in the native Persian race, for they have been from this time constantly subject to the domination of alien races. During the reigns of Omar (the first of the Arab caliphs of 632-644 A.D.) and Ali, and the latter's successors (656-750) Persia was regarded as an outlying province of the caliphate, and was ruled by deputy governors; but after the accession of the Abbasid dynasty (750) Baghdad became the capital, and Khurasan the favourite province of the caliph's ministers. A large part of this province of Persia consequently came to be considered as the centre and nucleus of the caliphate. But the rule of the califs soon became merely nominal, and ambitious governors, or other aspiring individuals, established independent principalities in various parts of the country. Many of these dynasties were transitory, others lasted for centuries, and created extensive and powerful empires. The chief were the Tahtites (829-872), a Turkish dynasty in Khurasan; the Saffarides (Persian, 869-903), in Seistan, Fars, Iraq, and Mazanderan; the Samanids, in Transoxiana, Khurasan, and Seistan; the Dilmuqs (Persian, 933-1056), in western Persia; and the Ghaznevids (Persian, q.v.), in eastern Persia. These dynasties supplied each other, and were finally rooted out by the Seljuks (q.v.), whose dominion extended from the Caspian Sea to China and India; and from the Ghaznavid dynasty, which ruled in Khorassan (now Khiva), gradually acquired the greater part of Persia, driving out the Ghaznevids and their successors, the Ghurids; but they, along with the numerous petty dynasties which had established themselves in the southern provinces of Persia, were all swept away by the Mongols under Genghis Khan (q.v.) and his grandson, Hulagu Khan, the latter of whom founded a new dynasty, the Perso-Mongol (1253-1333). This race, becoming effeminate, was supplanted by the Eylikhans in 1333; but an eruption of the Turko-Turanian people from their home beyond the Caspian claimed the dominion, with the assistance of the Tamerlaine dynasty, which ruled in Khorassan (now Khiva), for the next 300 years (1382-1687). The Turko-Turanian people, which consisted of Afghans and Turks, were divided into tribes and subdivided among Timur's descendants, till, at the close of the 16th century, they were swept away by the Uzbegs (q.v.), who joined eastern Persia to their newly-founded khanate of Khiva.

In 1606, during the reign of Shah Abbas (1587-1629), in western Persia, the first prince of which (Isma'il, the descendant of a long line of devotees and saints), having become the leader of a number of Turkish tribes who were attached by strong ties of gratitude to his family, overthrew the power of the Turkomans, and seized Azerbaijan, which was the seat of their power. Isma'il rapidly subdued the western provinces, and in 1611 took Khorassan and Balkh from the Uzbegs; but in 1614 he had to encounter a much more formidable enemy—to wit, the mighty Selim, the Sultan of Turkey, whose zeal for the further extension of religion and animosity against the Shiites (q.v.). The Persians were totally defeated in a battle on the frontiers; but Selim reaped no benefit from his victory, and after his retreat Isma'il attacked and subdued Georgia. Till then the character of this monarch, whom the Shah declared to be not only the restorer of Persia, but the establisher of the faith in which they glory as the national religion—viz. the Shiah, as distinguished from the Sunni sect of Mahomedanism. His son Taimur (1553-1605), a pugnacious man, and his spiritually inclined rule, eventually drove out the predatory Uzbegs from Khorassan, without losing a war with the Turks, and assisted Humayun, the son of Baber, to regain the throne of Delhi.

After a considerable period of internal revolution, during which the Turks and Uzbegs attacked the empire without hindrance, Shah Abbas II. (1629-1666) recovered the throne, restored internal tranquillity, and repelled the invasions of the Uzbegs and Turks. In 1665 he inflicted on the Turks such a terrible defeat as kept them quiet during the rest of his reign, and enabled him to recover the whole of Khorassan, Khorasan, and Dagesthan, which had for a long time been separated from Persia; and in the east Kandahar was taken from the Great Mogul. Abbas' government was strict, but just and equitable; roads, bridges, caravanserais, and other conveniences for trade were constructed at immense expense, and the improvement and ornamentation of the towns were not neglected. His tolerance was remarkable, as he encouraged the Armenian Christians to settle in the country. Of his successors, Shah Safi, Shah Abbas II., and Shah Solim, the two former were sensible and judicious rulers, and advanced the prosperity of their subjects. During the reign of Sultan Hussein, a weak and bigoted fool, priests and slaves were elevated to the most important and responsible offices of the empire, and all who rejected the tenets of the Shiites were persecuted. The consequence was a profusion of grievances, and so strong an advantage to declare their independence and seize Kandahar (1709). Their able leader, Meer Vais, died in 1715; but his successors were worthy of him, and one of them, Mahmud, invaded Persia (1722), defeated Hussein's armies, and besieged the king in Isfahan till the inhabitants were reduced to the extremity of distress. Hussein then abdicated the throne in favour of his conqueror, who, on his accession, immediately devoted his energies to alleviate the distresses and gain the confidence of his new subjects. Becoming insane, he was deposed in 1725 by his brother Ashraf; but the atrocious tyranny of the latter was speedily put an end to by the celebrated Nadir Shah (q.v.), who first raised Taimur (1629), of the Safavеev race, to the throne, then deposed him and made his young son the nominal sovereign, and finally, on the latter's death, deposed him and established Nadir Shah (1736). But on his death (1747) anarchy again returned; the country was horribly devastated by the rival claimants for the throne; Afghanistan and Beluchistan finally separated from Persia, and the country was spitted up into a number of small independent states till 1755, when they were united by Kerim Khan, who re-established peace and unity in western Persia, and by his wisdom, justice, and warlike talents acquired the esteem of his subjects and the respect of neighbouring states. After the usual contests for the succession, accompanied with the usual barbarities and devastations, Kerim was succeeded in 1784 by Ali-Murad, Jaafar, and Lutf-Ali, during whose reign Mazanderan became independent under Aga-Mohammed, a Turkoman eunuch of the Kajar race, who repeatedly defeated the royal army and ended by deposing Lutf-Ali of his crown (1795).

The great eunuch-king, the first of the present dynasty, on his accession announced his intention of restoring the kingdom as it had been established by Kerim Khan, and accordingly reinvaded the places that had been thrown away. He besought the aid of Russia; but the Persian monarch, with terrible promptitude, poured his army like a torrent into the country, and devastated it with fire and sword. His conquest was, however, hurriedly completed when he was assassinated (1797). His nephew, Shah Mohamad Shah, after numerous conflicts, fully established his authority, and completely subdued the rebellious tribes in Khorassan. But the great commotions in
western Europe produced for him bitter fruits. He was dragged into war with Russia, and, by his accession, and by a treaty concluded in 1797, surrendered to that power Derbend and several districts on the Kur. In 1802 Georgia was declared to be a Russian province. War with Russia was recommenced by Persia at the instigation of France, and, after a series of contests between the Persians, the treaty of Gulistan (1813) gave to Russia all the Persian possessions to the north of Armenia, and the right of navigation in the Caspian Sea. In 1826 a third war, equally unfortunate for Persia, was commenced with the same powers, and ended by ceding to Russia the remaining possessions in Armenia, with Erivan, and a sum of 18,000,000 rubles for the expenses of the war. The severity exercised in procuring this sum by taxation so exasperated the people that they rose in insurrection (1829), and murdered the Russian ambassador, his wife, and almost all who were connected with the Russian legation. The most humiliating concessions to Russia, and the punishment by mutilation of 1500 of the rioters, alone averted war. The death of the crown-prince, Abbas Mirza, in 1833, seemed to give the final blow to the fortunes of Persia, who were the only man who seriously attempted to raise his country from the state of abasement into which it had fallen. By the assistance of Russia and Britain Mohammed Shah (1834-48), the son of Abbas Mirza, who succeeded, was enabled to demand reacknowledgment of sovereignty from his alleged vassals in parts of Afghanistan, Beluchistan, and Khiva, but an attempt he made to reannex Herat, "the key to India," was resisted by England. The war was terminated in 1838 by the landing of a small sepoys force on the shores of the Persian Gulf.

Nasr-ed-Din succeeded to the throne on his father's death in 1848. The new government announced energetic reforms, but at first failed as completely as those which had preceded it in carrying them out. Following his father's example, the new Shah resolved to reassert his claims in Afghanistan and Beluchistan. The ruler of Herat having recognised the claims of Persia, the English government remonstrated with the Shah, and he was compelled to sign an engagement (1853), by which he became bound to maintain his frontier, and to interfere with the internal affairs of Herat. In 1856, however, on the pretext that Dost Mohammed, the Ameer of Kabul, was about to invade Herat, the Persians again took the city. Thereupon a British army, power on the north-east, while overrunning that of the gulf, and, under Generals Outram and Havelock, repeatedly defeated the Persians, and compelled them to restore Herat (July 1857). Since that time the Persians have not interfered with the "key to India," but they have been engaged in a long series of disputes with regard to their frontier north and south of Herat. After the war of 1857 their encroachments became systematic. In 1868 they occupied Seistan, a province claimed by the Afghan, and extended their jurisdiction over part of Beluchistan; but at length they agreed with the Ameer of Afghanistan and the Khan of Khiva to restrict the extent of their claims by an agreement with the latter and the British, made in 1868 in the presence of Lord Canning, at the Hague; in 1878 the town and territory of Khoufour, on the Turco-Persian frontier, was ceded to Persia by Turkey. The north-eastern frontier was settled by a treaty between Russia and Persia in 1881. The great extension of Russian territory and Russian power on the north-east, while overshadowing Persia to some extent, have had the effect of sheltering the adjoining regions of Persia from the terrible inroads of the Tekke and other Turkomans, and thus enabling English officers, including Sir John Bateman-Champain, Sir R. Murdoch Smith, Sir Oliver St John, and Captain Pierson, did much to explore and indirectly to improve the local government of Persia in connection with the establishment, in 1864, of the Indo-European telegraph line. Now there are 4500 miles of telegraph line in Persia, partly worked by Englishmen, partly by the Persian government. In 1896 Nasr-ed-Din was assassinated, and his second son, Mazaffar-ed-Din, peacefully succeeded to the throne.

Watson (1866), and Clemen's Markham (1874); Hawlinson's The Seventh Great Oriental Monarchy (1875); and Gude's History of Persia by Justi (1872), Niiilke (1877), and Gutsehman (1888).

PERSIAN ARCHITECTURE.—The architecture of Persia and that of Assyria closely resemble one another, and, owing to the mode and the materials in which they were constructed, their remains serve to illustrate and complete each other's history. In Assyria, where no solid building-materials existed, the walls are composed of masses of sun-dried brickwork, lined on the inside, to a certain height from the floor, with large sculptured slabs of alabaster. These have been preserved to us by the falling in of the heavy earthen roofs, with which, as the later Persian buildings explain to us, the Assyrian palaces were covered. The explorations of Layard and Botta have made these sculptures familiar to us. The Assyrian remains are all of palace-temples, buildings somewhat resembling the Egyptian temples were used as churches, and many of the sculptures represent the exploits of the king in war and peace. The palaces are always raised on lofty artificial mounds, and approached by magnificent flights of steps.

The buildings of Assyria are of two very early periods, the oldest at Nineveh being from 1300 to 500 B.C, and the more recent at Khorsabad and Kuyunjik from 800 to 600 B.C. To these succeeded Babylon in the reign of Nebuchadnezzar, and the Birs Nimrud; but these are mere masses of decomposed brickwork, without any sculptures of harder material (see ASSYRIA).

After Babylon ename Pasargadah, where the splendid palaces of Cyrus and Cambyses still exist, in ruins, and Persepolis, the capital of Darius and Xerxes (560-223 B.C.); and some remains are still to be found at Susa, Ecbatana, and Persepolis. At Persepolis we find the very parts preserved which at Ninimrood and Khorsabad are wanting; for here there is abundance of stone, and the pillars, walls, doorways, &c. (which in the early examples were on account of the risk of earthquakes) the sides of which are still preserved. This enabled Fergusson to restore these buildings; the subject has been further studied and illustrated with great care by M. Dieulafoy in L'Art Antiqu de la Perse (1884).

The halls at Persepolis were square in plan, having an equal number of pillars in each direction for the support of the roof, which was flat. In the
In 1886 some extremely interesting discoveries were made at Susa (Shushan) in south-western Persia by M. and Madame Dieulafoy, who unearthed and sent to the Louvre a splendid frieze in coloured enamelled bricks with life-sized figures of warriors from the palace of Darius I., and another similar frieze with lions from the palace of Artaxerxes. A fac-simile reproduction of the warrior frieze is in the Edinburgh Museum of Science and Art.

Modern Persian architecture is separated by a wide historic gap from that of ancient Persia, and, all posterior to the Moslem conquest, belongs to the type known as Saracenic or Arabian. But it seems that the old art of Persia has a more direct influence on that of modern Persia than has been sometimes admitted; and even the Egyptian type of Saracenic art (see ARABIAN ARCHITECTURE) may have been moulded by Persian as well as by Byzantine artists, working for the Moslem conquerors. In Persia itself there seems no doubt that architecture of Mohammedan Persia, which in its palmiest days rivalled in splendour that of Egypt, Bagdad rivalling with Cairo, is in many respects a reproduction of the ancient palaces of Nineveh and Babylon. In the mosques thick walls of imperfectly burnt bricks are covered with brilliantly coloured decorations of glazed and painted tiles and bricks. Fig. 4 is a view of the gateway of the Masjid Shah, or Great Mosque of Isphahan, dating from the reign of Shah Abbas the Great (1585-1628 A.D.).

PERSIAN LANGUAGE AND LITERATURE.—The ancient and modern idioms of Persia, which are in general designated as Iranian or West Aryan, belong to the great class of the Indo-European languages; but the term Persian itself applies more particularly to the language as it is now spoken, with a few exceptions, throughout Persia, and in a few other places formerly under Persian dominion, like Bokhara, &c. The more important and better known of the ancient idioms are (1) the Zend (the East Iranian or Bactrian language, in two dialects—the ‘Gatha idiom’ and the capitals, composed of bulls' heads and shoulders (fig. 2), between which the beams of the roof rested; while others were ornamented with scrolls like the Ionic order (fig. 3). The bases also are suggestive of the origin of that Greek style. This hall was 350 feet by 300, and covered more ground than any similar buildings of antiquity, or any medieval cathedral except that of Milan. The palaces of Persepolis stand on lofty platforms, built with walls of cyclopean masonry, and approached by magnificent flights of stairs, adorned, like the palaces, with sculptures somewhat similar to those of Assyria. The interiors were ornamented with paintings. The use of the arch was known in Assyria, as has been shown by the subterranean arched conduits discovered by Layard, and the gates of Khorsabad discovered by M. Place. The arches of the latter spring from the backs of sculptured bulls, and are beautifully ornamented with enamelled bricks.

Fig. 2. Details of Persian Architecture.

Fig. 3.

centre a portion was left open for the admission of light, and sheltered by another roof raised upon pillars. The remains of the seventy-two columns with which it was adorned are still extant (fig. 1). The hall had thirty-six columns, six on each side, and on three sides there had an external portico, each with two rows of six columns. These columns had
ancient’ or ‘classical Zend’), which died out in the 3d century B.C.—one of the most highly developed idioms, rich in inflections, in the verbs as well as in the nouns, and in the former almost completely agreeing with Vedic Sanskrit; yet such as it is, it is the better absolutely abandoned, for it has survived it is no longer in the full vigour of life, but almost decaying, and grammatically somewhat neglected. Geographically, this idiom may be placed in northern Persia. Its alphabet is of Semitic origin, and the writing goes from right to left. There are three distinct idiom: first is Persian, the chief remnants of which are found in the cuneiform inscriptions of the time of the Achemenides, discovered in the ruins of Persepolis, on the rock of Behistun, and some other places of Persia (see CUNEIFORM). Some relics, chiefly consisting of proper names for gods and men, and terms for vessels and garments, have survived in the writings of the classical period, and in the Bible, chiefly in Daniel. This idiom is much nearer to Zend and Sanskrit than to modern Persian, the Persians (Persian, Mede, or Persian, in use during the period of the Sassanian [3d to 7th century A.D.], is an idiom largely mixed with Semitic words, and poorer in inflections and terminations than Zend. Its remnants consist of a certain number of books relating to the Zoroastrian belief and religious degree in which it was used. The language is not quite the same in all cases—according to the larger or smaller infusion of foreign words. The non-Iranian element is known as Huzvareh, and is simply Chaldee; while the Iranian element is but little different from modern Persian. They are distinguished in Pehlevi, and the writing varies accordingly, yet it is not certain whether the difference arises from their belonging to different districts or periods. When, however, Pehlevi ceased to be a living language, and the restoration of the pure Iranian had begun, people began to use the writing (chiefly of a sacred nature, as having descended to them from the Sassanian times) began to substitute in reading the Persian equivalents for the Huzvareh words. At last a new form of consonants to the sacred writing began to be distinguished into Zend characters by the Perseans, and the language was continued to be used, where each sign had but one phonetic value, and where all the foreign Huzvareh words were replaced by pure Persian ones; and this new form was called (4) Pehlevi. The transition from the Zend写作 to the modern language is called the Parase, or, as the Arabs and the modern Persians themselves call it, Farsi, in use from 700 to 1100 A.D., since the language purely of the south-western provinces, and distinguished chiefly by a peculiar style, rigid exclusion of Semitic words, and certain now obsolete forms and words retained in liturgical formulas. It is the Persian once written by the Parsees or fire-worshippers, and is in other respects very similar to the present or modern Persian (which also is invariably called Farsi by the modern Persians), the language of Jami, Nizami, and Hafiz. It is the most sonorous and muscular, while at the same time it is the most elegant and most flexible of idioms; and it is not to be wondered at that in Moslem and Hindu realms it should have become the language of the court and of the educated world generally in Persia, and thereby escape the decay which its analytical and grammatical structure, it exhibits traces only of that of the ancient dialects of Zend and Achemenian, of which it is a direct descendant. The elaborate system of forms and inflections characteristic of those dialects has been by general admission abandoned, but the peculiarities, which impart fullness and an incredible ease to speech and composition. The grammar of the Persian language has been called ‘regular,’ but the fact is that there is hardly any grammar worthy of mention. Thus, there is no gender distinguished in Zend, and the plural is as much a philological as a grammatical word, in such manner, the only distinction consisting in animate beings receiving the affix an, while the inanimate are terminated in ha. Imported Arabic nouns, however, invariably take their Arabic plural. Not even the pronouns have a gender of their own; the distinction between masculine and feminine must be expressed by a special word, denoting male or female. There is no article, either definite or indefinite. The flexion of the verb is equally simple. As to syntax, there is much, or, at all events, none which would not come almost instantly to anyone acquainted with the general laws of speech and composition. The time of its greatest brilliancy may be designated as that in which Firdusi wrote, when Arabic words had not swamped it to the vast extent that they have since done: the Persian remained still, as far as they had crept in, amenable to whatever rules the Persian grammar imposed upon the words of its own language. In the history of the Persian writing three epochs are to be distinguished. First, we have the Cuneiform epoch (B.C.), in the time of which there seems to have been in use a kind of Semitic alphabet for common purposes. This, in the second period, appears to have split into several alphabets, all related to each other, and pointing to a common Semitic origin (such as the different kinds of Pehlevi characters and the Zend alphabet) merely adapted to the use of a non-Semitic language. In the third period we find the Arabic alphabet enlarged for Persian use by an addition of diacritical points and signs for such sounds as are not to be found in Arabic (p, d, zh, g). The writing is but slightly different from the language which the ancient Persians used, however, to be in use a kind of Semitic alphabet for common purposes. Of the literature of the Persians before the Mohammedan conquest we shall not speak here, but refer to the article ZEND. The literary period now under consideration is distinguishable from its antecedents only by the fact that it was the period of the transition from Zend to the Persian language, and into the Persian language, imported together with the Koran and its teachings. The writers are one and all Mohammedans. With the fanaticism peculiar to conquering religions, all the representatives of old Persian literature and science, men and matter, were ruthlessly persecuted by Omar’s general, Saad Dam Abi Wakkas. The consequence was that for the first two or three centuries after the conquest all was silence. The scholars and priests who would not bow to Allah and his Prophet were put to death, others were destroyed or changed in the written word or in the oral tradition of that ancient culture, while those that remained at home were forced to abandon their wonted studies. Yet, by slow degrees, as is invariably the case under such circumstances, the conquered race transformed the culture of the conquerors to such a degree that native influence was paramount in Persia, even in the matter of theology. It is readily granted by later Mohammedan writers that it was out of the body of the Persians exclusively that sprang the foremost, if not all, the greatest scholars and authors of the Persians as well as of grammatical subjects, historians and poets, philosophers and men of science; and the only concession they made consisted in their use of the newly-imported Arabic
The Persian language. A further step was taken when the Persians, under upstart native dynasties, returned also to the ancient language of their fathers during the first centuries of Mohammedanism. The revival of Arabic bellicose and pagan sentiment was long lingering for a long time previously among the masses, then suddenly burst forth in prose and in verse, from the lips of a thousand singers and writers. The literary life of Persia, the commencement of which is thus to be placed in the 6th century A.D., existed in harmony with undisturbed gaiety for five centuries, and produced a host of writers in every branch of science and belles-lettres, of whom we can only here give the most rapid surveys, referring for the most important names to special articles.

At the 932 Abul Hassan Rudogi, the Blind, rose by the king's favour to such an eminence that he had two hundred slaves to wait upon him; but little has remained of his 1,300,000 distichs, and of his metrical translation of Bidpai's Fables. About 1000 we hear of Kubar, the Dilmunite prince, as the author of The Poem of Erode, and poems. In the time of the Ghaznevids, chiefly under Mahmud, who surrounded himself with no less than four hundred court-poets, we find those stars of Persian song, Anvari (1069), author of Wazik and Aura; Feruachi, who, besides his own poetic first work, wrote laws of the Persian metrical art; Eseli, from Tus; and, above all, Firaulani (q.v.), the author of the Shah-Namaeh. Under the Atabek dynasty was the panegyrist Ashad-ed-Din Anvari, who, with his praise, well knew how to handle satire. Nizami (about 1260) is founder of the romantic epic; while Persia is the mystic (Sufistic) poetry, which, under Anamcric and allegorical, in glowing songs of wine and love, represented the mystery of divine love and of the union of the soul with God (see Sufiism). In this province we find the famous Omar Khayyam (q.v.; died 1123), and Farid-ed-Din Attar (born 1216), the renowned author of Pend-Namaeh ('Book of Counsel'), a work containing the biographies of saints up to his own time; such is the depth and hidden meaning of his mystic poems that the whole modern world has basied itself with commentators on the meaning of his sacred poetry. He died about 1330, more than a hundred years old, as a martyr. Greater still in this field is Jalal-ed-Din Rumi (died 1273), whose poem on Contemplative Life has made him a master of mysticism, which is up to this day; he wrote also a great number of lyrical poems. The 13th century cannot better be closed than with Sai'di (q.v.), the first and unrivalled Persian didactic poet. But far above all shone Hafiz (q.v.), who sang of wine and love, and nightingales and mountain flowers. After him the full glory of Persian poetry begins to wane. Among those that came after him Jami (1419-92) stands highest, a poet of most varied genius, second only in every one of the manifold branches to his chivalric and didactic and Sa'di, in romance to Nizami, in mysticism to Jalal-ed-Din, but most brilliant as a romantic poet. Of prose works we have by him a history of the Sufis, and an exceedingly valuable collection of epitaphs and models. The dramatic poetry of the Persians is not without modern extension. The numerous tales, stories, novels, anecdotes, anthologies, and all the miscellaneous entertaining literature in which Persia abounds form a fit transition from prose to poetry. Able rivals of the great Arabic histories have sprung up at an early period. For the mythical time of the Persian gian's gigantic eyes remains the only source. Reshid-ed-Din, the vizier of Ghazan (born 1247; executed in 1320), wrote a summary of the history of all Mohammedian countries and times, containing besides a complete history of sects. His contemporary Wassis is the model of the grand rhetorical style. His most successful imitator in the 15th century was Shams ibn-Din, who wrote the history of Tamerlane. Up to the end of the period there has been considered the principal beauty, if not the chief merit, of a classical Persian history. From the 16th century downwards a healthy reaction set in, and simplicity and a striving for the real representation of facts became the predominant fashion. Foremost amongst these modern historians is Khusraw, whose Universal History comprises the period from creation to the reign of Sultan Hasan Behkarn. His son Khondemir also wrote history. Among Indian historians who wrote in Persian we have Mohammed Khusro Pershtal (1640), who wrote the ancient history of India up to the European conquest, and Mohammed Haslim, Abul Fadel Moharek, and others. The Meahar Sultanwye, which contains the history of the present dynasty of Persia, and was published at Tehran in 1825, was translated by Briquet.

Biographies, legends, histories of martyrs, and the like are legion. Most of the biographies of the Prophet, however, are taken from the Arabic. Works on geography—generally treated together with history—are those of Mestafi, Alhin Ahmed, Nizami, Rudegi, Bonit, and in the translations of the Koran, commentators and Frenchmen's, and the portions of the Traditions has been produced. Jurisprudence has likewise to show little that is original, and not mere translation, partial commentary, or adaptation in Persian. The Hedadshi, the Jami, the Peniian Alemgiri are the most important legal works. Much has been written on medicine, surgery, pharmacy, and physical sciences by Persians, but nearly all their chief works are in Arabic. Mathematics, astronomy, and philosophy have not been neglected; rhetoric, works on letter-writing, and on numerical and poetical arts are numerous. Grammar and lexicography found their principal cultivators in India. Translations from Greek, Indian, Arabic, Turkish, and other languages into Persian exist in abundance.

There is no good history of Persian literature; but there is a mass of information in the following, of Stewart (1809), Ouseley (1831), Morley (1854), Spengler (Calcutta, 1854), Eien (Long. 1879), and others. See the articles in this work on FIRDOUSI, HAFEZ, OMAR HAYYAM, BAYTAI, KHOA'N, and others. Among women's, are those of Johnson and Richardson, Vullers (1867), Palmer (1876-84), Steinag (1884-92), Wollaston (1888).

Persian Gulf, an arm of the Indian Ocean which penetrates between Arabia and Persia to the extent of 650 English miles in a general north-westward direction. Its breadth varies from 35 miles at the mouth to 250 miles, and the area is estimated at 77,450 sq. m., not including the islands, which are scattered over the western half, or lie close inshore along the eastern side. The chief of these islands are Ormus, at the mouth; Khush, 810 sq. m, in extent, and the Bahrein Islands. The Great Pearl Bank stretches along the western side from Ras Hassan to nearly half-way up the gulf. The coast is mostly formed of calcareous rocks. On the Arabian side it is low and sandy, occasionally broken by mountains and cliffs; while on the Persian side it is higher and abrupt, with deep water close inshore, owing to the mountainous country of Fars and Luristan running close to the water's edge. The islands are partly of limestone and partly of ironstone, and are generally destitute of springs, barren, desolate, and presenting numerous masses of cactus, salt, and mud eruptions. Excepting, the Shat-el-Arab (see EUPHROTES), the Persian Gulf receives only insignificant streams. Its eastern side presents
abundance of good anchorage, either in the numerous bays or in the lee of islands. The greater portion of its southern shores now belongs to the Iman of Muscat, while the whole of the northern shore belongs to Persia. The order of the periodic currents in this gulf is precisely the reverse of that of the Red Sea. They commence from May to October, and descend from October to May. The greatest depth does not exceed 50 fathoms; and Dr John Murray calculates its total cubic contents at 2200 cubic miles of water. Oriental geographers give to this gulf the name of the Great Sea, a title used to denote the Mediterranean, -a green colour, lying along the Arabian coast.

The submarine telegraph cables belonging to the government of India, and forming part of the system of the Indo-European Telegraph, pass through the whole length of the Persian Gulf, from Fao at the mouth of the Shat-el-Arab, where they connect with the Turkish lines, to Bashire, where they connect with the Persian, and thence to Jask, Gwadar, and Kurraheee, where they connect with the general telegraph system of India. Among the ports are Bender Abbas (q.v.), Bashire (q.v.), and Bushire (q.v.).

Persian Powder. See Insect-Powder.

Persigny, Jean Gilbert Victor Flaran Du C du, an adherent of Napoleon III., was born at Saint-Germain-l'Esparre (dept. Loire), 11th January 1808, entered the cavalry school at Saumur in 1826, and the 4th Hussars in 1828; but he was expelled from the army for insubordination in 1831. Then, having been introduced to Louis Napoleon, he secured his favour, and commenced a career of Bonapartist propagandism throughout France and Germany. He had the chief hand in the affair of Strasburg (1836) and in the descent on Boulogne (1840), but was captured there, and condemned to twenty years' imprisonment. On the breaking out of the revolution in 1848 Persigny was one of the men who secured the election of Napoleon as President of the Republic; he also took a prominent part in the coup d'etat of December 1851. In January 1852 he succeeded De Morry as minister of the Interior; from 1855 to 1860 (except for one year) he was ambassador at the English court; then he resumed the office of minister of the Interior until June 1863. In September of the same year he was created duke. Thereafter he sat in the fall of the empire, when he escaped to England. He died at Nice on 21st January 1872.

Persimmon. See Date Plum.

Persius (Aulus Persius Flaccus), third in the line of Roman satirists, being later than Lucilius and Horace and earlier than Juvenal, was in some respects the ablest, certainly the most dramatic, of the four. Born of a distinguished equestrian family, 4th December 34 A.D., at Volaterrae in Etruria, he lost his father when six years old, was educated till twelve in his native town, and thereafter in Rome under the grammarians Remusius Palanen and the rhetorician Virginius Flavius. In 10 B.C. he lost his mother and affection to Seneca, to which, on the recommendation of the Stoic philosopher Cornutus, who imbued him with the tenets of his school and gave his mind and character an impress which ever deepened and strengthened. But he died before connecting his twenty-eighth year.

The selection entertained by the master for his pupil was shared by the friends of the latter—Lucan, Celsus Bassus, the lyric poet, and other contemporaries of light and learning, among whom, however, Seneca had little estimation. The noble and virtuous Peter Trissene accompanied him on several tours through Italy, finding a kindred soul in the modest, prepossessing youth, whose integrity and piety were conspicuous in his worldly as in his family relations. The austere discipline of Cornutus affected the style of Persius, who, in consequence wrote fastidiously and sparingly, leaving at his death six brief satires, the whole not exceeding 650 lines. These were slightly corrected by Cornutus and edited by Casaubon. Persius, however, even through the early mediaval darkness till the Renaissance and down to our own day, the highest esteem, fathers of the church like Augustine and Jerome, humanists like Buchanan and Casanov, antinomists like the Pietists, have been evolving and interpreting the poet's pregnant, if sometimes obscure, ridicule of the rapidly degenerating life of 1st century paganism. The best satire is, on the whole, the first, on the prevailing false taste in poetry. 'Probably no writer ever borrowed so much and yet left on the mind so decided an impression of originality,' says Conington, who further indicates the striking resemblance between the genius of Persius and that of Carlyle. He has had many editors, of whom the most helpful have been Casaubon (1693), Otto Jahn (1843-68), and Conington, whose revised edition (Oxford, 1873), gives text, prose translation, and notes embodying the best results of previous criticism. He has had a host of translators in the chief modern languages—that of the Italian Sacchi of Faenza surpassing all others, not excepting the English versions by Drayton and Gifford.

Person (Lat. persona, 'a mask') came to be applied to the person wearing the mask, and thus to mean a personage, an individual, a numerically distinct being. In theology there is a special use of the word for the three Persons of the Trinity (q.v.). The name Person, when applied to the Trinity by the Latins; the corresponding Greek word, Prosopon, being of later use. The earlier Greek Fathers used the word Hypostasis, 'substance,' where the Latins used Persona, and considerable controversy for a time grew out of this diverse use; after the condemnation of the Sabellian heresy, and still more after the Council of Nicea, all ambiguity of words being at an end, the controversy turned upon the substance of the doctrine, in the form of the Arian controversy. See ARIUS.

Personal Equation. See Equations.

Personal Exception, in the law of Scotland, the equivalent of the English Estoppel (q.v.); a ground of objection which applies under the name of Double Personality or Double Consciousness; the records of medical science contain many
cases of mental disorder, in which the sense of personal identity is curiously interfered with. Cases are, of course, of constant occurrence in which the patient mentally affected conceives himself to be some one else (e.g. Napoleon or a Scripture character). Others conceive that parts or properties of their frame belong to another person, that they are inhabited and ruled by a spirit or entity acting in opposition to their will and interests. Others, again, are possessed by the idea that they are two persons at once, or rather that their body is the seat of two beings who are often in strife together, one being generally identified more strictly with the self, and the other being regarded as a hostile power and a manvatis suget who prompts the better self to evil courses. The struggle between the two persons of this duality often takes bodily shape, and the patient maltreats his own body under the impression that he is castigating the vicious 'other one' who haunts him. This alienation or extrusion of part of the individual's experience from the inner circle of the personality may be due, it has been suggested, to a more or less profound automatism in the consciousness of the state of the body as a whole. Any part of the body in which this common sensibility is wanting or disturbed is regarded by the patient as no longer a part of himself, and even as belonging to some hostile being. Even hallucinations of such somatic insensibility that the individual doubts or denies his own existence, as in the case of a patient cited by Ribot, who declared that he had been dead two years, though (according to his own account) he still continued to exist in a somnambulistic fashion in which he was not consciously interested. These manifestations, however, are not what is meant by double consciousness in the strict sense of the term. Double consciousness does not necessarily imply the presence of any insane delusion as to the patient's present existence and surroundings, but consists in the fact that a certain portion of his past life is temporarily withdrawn altogether from his conscious memory, to reappear, however, at a later period, when he will have as completely forgotten this previous experience and the whole section of his life connected with them. In the normal human being the memory is unitary, and consequently the life-experiences of the individual are felt and recalled as parts of one whole. In those morbid cases, on the contrary, the conscious life appears, as it were, to be cut into sections of lengths which are entirely disjuxtaposed, and retained, so to speak, in separate memories. These mutually exclusive sections are remembered by the individual intermittently in successive periods, generally separated from one another by a somnambulistic, drunkenness, as to the patient's present existence and surroundings, and gradually become acquainted with the persons and objects around him, like a being for the first time brought into the world. In these exercises she made considerable proficiency. But after a few months another fit of somnambulism invaded her. On rousing from it she found herself the same as in the former state she was in another person, but the paroxysm, but was wholly ignorant of every event and circumstances that had befallen her afterward. She is as unconscious of her double character as two persons are of their respective natures. For example, in her old state she possesses all the original knowledge, in her new state only what she acquired since. In the old state she possesses fine powers of pensmanship, while in the new she writes a poor, awkward hand, having not had time or means to become an expert. A similar experience is observable in the case of somnambulists, who are totally ignorant, in the waking state, of their somnambulistic experience, but when again in the somnambulistic state recall what happened in the previous crisis. Lost objects have been recovered, and even crimes brought to light by taking advantage of this peculiarity. The same phenomenon is observable even in the cases of intoxication, when a woman, in one fit of drunkenness being remembered in the next, but forgotten in the sober interval. Instances of double consciousness, however, are not always of the precise type mentioned by Macnich. Thus, in one of the cases of somnambulism cited by Félicité X, reported by Dr Azani, the woman was conscious during the second state of her whole life-experience, but during the first or original state knew nothing of anything that had happened in the second. The alternations began in this case in 1856, and continued for more than thirty years, and it is remarkable that the second state, which at first appeared only in short dream-like periods, has gradually supplanted the first state, which now recurs only at long intervals, and for a few hours. The second state is physically and mentally superior to the first, and the patient herself speaks of the first as état bête. A still more extraordinary case, reported from Paris, is that of Louis V., a young man of epileptic and hysterical temperament and criminal tendencies (born 1863), where, as a result of his treatment, six states which are mutually exclusive, but which, taken together, embrace his whole past life. These and other cases are commented upon by Ribot in his Diseases of Memory and his Mélanges de la Personnalité, and by Mr F. W. Myers in an article on 'Multiple of Personality' (Mind, November 1886). The phenomena of double consciousness have also been aptly described as periodic amnesia. They evidently depend upon morbid action of the brain—it has been suggested, upon an abnormal severance and consequent independent action of the two hemispheres—but the physico- logical conditions are still full of obscurity. An ingenious literary use of the notion of double personality, on completely different planes of morality, is seen in Mr R. L. Stevenson's creation of Dr Jekyll and Mr Hyde.

**Perspective** (Lat. perspectio, 'I look through') is the art of representing several objects on a plane surface in such a manner that the representation shall affect the eye in the same way as the
objects themselves. The distance and position of objects affect both their distinctness and apparent form, giving rise to a subdivision of perspective into *linear perspective*, which, as its name denotes, considers exclusively the effect produced by the position and distance of the observer upon the apparent form and grouping of objects; while *aerial perspective* confines itself to their distinctness, as modified by distance and light. The necessity of attending to the principles of perspective in all pictorial drawing is apparent when we consider, for instance, that a circle when seen obliquely appears to be a long one, with its shortest diameter in line with the spectator, and its longest at right angles to this. A square, when looked at from a position opposite the middle of one of its sides, appears as a trapezoid, the sides which are perpendicular to the direction of vision appearing to be parallel, while the other two appear to converge to a point in front of the spectator, &c.

For the same reason two rows of parallel pillars of equal height, seen from a point between and equidistant from each row, appear not only to converge at the further end, but to become gradually smaller and smaller. An excellent idea of a perspective plan can be easily obtained by interposing a vertical transparent plane (as of glass—a window, for instance) between the observers of his vision, and supposing that the objects he sees are not seen through the glass, but painted on it. A sketch made on a glass plane, in this position, by following with a pencil all the lines and shades of the objects seen through it, the eye being all the time kept quite steady, would form a picture in perfect perspective. In practice, however, it is found unfortunately that glass is not a suitable material for sketching on, and that the vertical position is not the most convenient; it is therefore preferable to make a careful study of the effects produced by change of position and distance on the appearance of objects in nature, and from the results thus obtained, by the observance of which painters may be enabled to produce an effect true to nature. After the 'scope' (i.e. the number of objects to be introduced, and the distance at which they are to be viewed) of the picture has been determined, and before the sketch is commenced, it is necessary to draw upon the perspective plan three lines: (1) The base line, or ground line, limits the sketch towards the operator, and is the base line of the picture. (2) The horizontal line represents the ordinary position of the sensible horizon. The height of the horizontal line is about one-third of the height of the picture, when the sketcher is placed at or little above the level of the horizon; but it may rise in a degree corresponding to his increase of elevation till it reaches near to the top of the perspective plan. The general rule is to have a high horizontal line when the view is taken, or supposed to be taken, from an eminence; but when the station is on a level, either actual or assumed, as is the case when a statue or a magnificent landscape is figured, the horizontal line may be low. The line when the view is taken, or supposed to be taken, from an eminence; but when the station is on a level, either actual or assumed, as is the case when a statue or a magnificent landscape is figured, the horizontal line may be low. (3) The vertical line is drawn from the supposed position of the spectator, perpendicular to the ground and horizontal lines, meeting the latter in a point which is called the point of sight, or center of projection.

All vertical lines in nature being parallel to it in the picture. The point of sight, being the point directly opposite to the observer, is properly placed in the centre of the picture, for it is most natural that the view should lie symmetrically on each side of the principal visual line; but this is not by any means a universal rule, for we very frequently find it on the right or left side, but always, of course, on the horizontal line. All lines which in nature are perpendicular to the ground line, or to a vertical plane which is raised upon it as a base, meet in the point of sight, which is thus their vanishing point (see the line of the tops and bottoms of the pillars in fig. 1). The points in the horizontal line on each side of the point of sight, and in a 'direct' sketch are at a distance from it equal to the horizontal distance of the spectator's eye from the ground line. The equality of distance of these points from the point of sight is not, however, necessary, as it occurs only in those cases where the lines, of which the points of distance are the vanishing points, are inclined (in nature) at an angle of 45° to the base line; but in all cases the two points of distance are about twice as far apart as the eye is from the picture. One important use of the points of distance is to define the distance of objects in a row (fig. 1) from each other. For this purpose two points of distance are not necessary, as when the position of one pillar is found, that of the one opposite is at once obtained by drawing a line parallel to the base or ground line. We have seen that the point of sight is the vanishing point of all lines, and that the ground line is a vertical plane on it at right angles, and that the points of distance (in a direct picture) are the vanishing points of all lines which cut the ground line at an angle of 45°; but there are many other groups of parallel lines in a picture which have different situations, and therefore different vanishing points. Such lines with their vanishing points (called for distinction's sake accidental points) are represented in fig. 2. If the accidental point is above the horizontal line, it is called the accidental point aerial; if below, the accidental point terrestrial; and a little consideration makes it evident that these points may or may not be situated within the plane of the picture. Such are the points and lines necessary for the construction of a plan in true perspective; and from the above explanation we may deduce the two general principles: (1) that all parallel straight lines in nature are no longer parallel when projected on the perspective plane, but meet in a point which is called the vanishing point, and is some one of the three above described, unless these lines happen to be also parallel to the ground line or the vertical line, in which case they remain parallel when transferred to the picture; and (2) that, since the bodies drawn below the horizontal line are seen as if from above, those above as if from below, and those to the right as if from the left, the left of the spectator's eye, if observed from the left and right, it follows that straight lines which in the picture are above the horizontal line lower themselves, those below raise
Aerial perspective consists in a modulation of the brightness and colours of objects in accordance with the state of the atmosphere, the depth of the body in the perspective plane (i.e. distance in nature from the ground line), and other accidents of place and time. As the distance of objects increases, their illuminated parts are made less brilliant and their shaded parts more feeble. The bluish tint imparted by a large mass of the atmosphere to the bodies seen through it is frequently imitated by the mixing of a slight tint of blue with the colours to be applied; a yellow object thus assumes a greenish tint, a red one a violet tint, &c. The air when charged with vapour is represented by a diminution of the brightness of colours, and by the grayish tint imparted to them. But in this part of the subject rules are of little avail, for experience alone can guide the painter in faithfully copying the myriad aspects presented by nature.

A thorough knowledge of perspective is a sine qua non to the painter or designer, and though many are inclined to think it a superfluity, and that the sketcher has only to make use of his eyes and copy justly, the very fact that such is their opinion shows that they have never made the attempt: for it is impossible for the painter, and much more so for the designer, to execute a copy of nature with sufficient accuracy by the sole aid of the eye and hand, a fact that is unfortunately too frequently proved by many of the sketches exhibited in fine-art collections. Perspective was known to the ancients, but seems to have become extinct during the disturbances that convulsed Italy, and was revived by Albert Dürer and Bramantino of Milan (c. 1470-1535), whose body of rules was extended and completed by Perruzzi and Ubaldi about 1600. Dr Brock Taylor in 1715 and 1719 was the first Englishman who discussed the subject scientifically.

There are works on perspective by Trywhitt (1668), Humphris (1699), Collins (1672), Dennis (1677), Pellegrini (New York, 1674), Barchetti (1801), Miller (1807), and James (1808).

Perspiration. See Skin.

Perth, the county town of Perthshire, on the right bank of the Tay, is 43 miles NNW. of Edinburgh, 22 WSW. of Dundee, and 92 NW. of Glasgow. The beauty of its surroundings—the noble river; the two wooded heights, Moncreiffe and Kinnoull Hills, 725 and 730 feet high; and, away to the north, the Grampians—makes the 'Fair City' worthy of the name. A handsome nine-arch bridge (1772; widened 1871), 840 feet long, and stretching over a waterway of 500 feet, leads to the suburb of Bridgeend, where Ruskin spent much of his childhood, on the east bank of the Tay; along the west bank are beautiful public parks, the North and South Inches, 98 and 72 acres in area. St John's Church, whose restoration was undertaken in 1891, is the only old building—a cruciform Decorated pile, with an earlier central square tower. Other edifices are St Ninian's Episcopal Cathedral, a Early Middle Pointed structure, by Butterfield; the Tudor municipal buildings (1879), the Grecian county buildings (1819-67), the city hall (1844), the infirmary (1857-69), and the penitentiary and general prison for Scotland (1812-59), besides which may be noticed the water-works (1830-80), two museums, the Albert statue (1864), and the auction-mart (1876). Railways have largely diverted the river-trade; and dyeing is now the leading industry, with manufactures of ink, gauge-glasses, hosiery, iron, beer, &c. A royal burgh since 1210 or earlier, and taking precedence of all others save Edinburgh, Perth returns one member.

Pop. (1831) 19,238; (1861) 22,230; (1891) 29,599.

Perth, or St John's town, as it was formerly called, has a wealth of historic memories—the bloody encounter on the North Inch between sixty clans Chattan and Kay (1566); the murder of James I. (q.v., 1457); Knox's thundering sermon against idolatry in St John's (1569); the Gowrie Conspiracy (q.v., 1600); and Montrose's victory of Tippermuir (1644); besides sixteen ecclesiastical councils and fourteen parliaments, and visits innumerable from royal personages, including both the Pretenders and Queen Victoria. James, fourth Lord Drummond, was in 1605 created Earl of Perth; in 1607 by the Jacobite fourth earl (titular Duke of Perth), and restored in 1833 to George Drummond, sixth De Selincourt.

The Five Articles of Perth, memorable in the ecclesiastical history of Scotland, were agreed upon in a meeting of the General Assembly, convened at Perth, by command of James VI. in 1618. They enjoined kneeling at the Lord's Supper, the observance of Christmas, Good Friday, Easter, and Pentecost, and confirmation, and sanctioned the private administration of baptism and of the Lord's Supper. Highly objectionable to the Presbyterians as having been adopted in mere compliance with the king's will, they yet were ratified by the parliament, and enforced by the Court of High Commission. They became one of the chief subjects of that contention between king and people which produced results alarming and sad for both in the subsequent reign. The General Assembly of Glasgow in 1638 declared that of Perth to have been 'unfree, unlawful, and null, and condemned the Five Articles.

See Perth Memorials (1806), Maidment's Chronicle of Perth (Maitland Club, 1831), and works by Penny (1806) Lawson (1847), Peacock (1849), and J. Wilson (1860).
PERTH, the capital of Western Australia, occupies a picturesque site on the north bank of the Swan River, 12 miles from the sea. Its port, at the mouth of the river, is the headquarters of banking for the colony, and the centre of the principal railway lines, including the Great Southern Railway to Albany. The most important building is the Government House, the Protestant (1888) and Roman Catholic cathedrals, the university, the state library, the institute and museum, and the governor's residence. 

Perth, capital of Lanark county, Ontario, on the Black Water, 141 miles by rail, SW. of Montreal, contains mills and manufactories of machinery, leather, woolens, &c. Pop. 2467.

Perth Amboy, a port of entry of New Jersey, on the Kill van Kull, 26 miles by rail SW. of New York. There is a steam-ferry to Tottenville in Staten Island. Pop. (1900) 17,699.

Perthes, FRIEDRICH CHRISTOPH, German publisher, was born at Rudolstadt, 21st April 1772, and learned his business in Leipzig. In 1810 he started the National Journal, which enjoyed the patronage of the most influential writers of the day, and took an active personal part in resisting the establishment of French authority in Hamburg and Germany. Having built up his business again during the first years of peace, he removed in 1821 to Gotha. There his greatest work was the publication of works on all European nations, edited by Heeren, Ubert, and Giesebricht. He died at Gotha, 18th May 1843. See Life (6th ed. 1872; Eng. trans. 1878) by his son Clemens Theodor. —JOHANN GEORG JESTER.

Perthes (1740-1816), an uncle to Friedrich, established a publishing-house at Gotha in 1785, which has acquired in the hands of his sons a great reputation as a geographical institute; it issues Petermann's Mitteilungen, Steiler's Atlas, numerous books of travel and geography, and the Almanack de Gotha.

Perthshire, the fourth largest county of Scotland, bounded by Inverness, Aberdeen, Forfar, Fife, Kinross, Clackmannan, Stirling, Dunbarton, and Argyllshire. Its greatest length, from east to west, is 77 miles; its greatest breadth, from north to south, 68 miles; and till 1891 its area was 290,353 acres, of which 28,274 were water. In that year no fewer than eighteen alterations were made by the boundary commissioners, Perthshire receiving eight small enclaves from Ffarar, Fife, Kinross, and Stirling shires, whilst giving off to the last three lands, like nupts, including the Culross and Tulliallan portion (13,125 acres). Partly Lowland, but mainly Highland (Strathmore the dividing line), it is called by Scott 'the fairest portion of the northern kingdom;' and such, indeed, it is, with its mountains and glens, its riverine, lakes, and fertile valleys, and fertile pastures. At the chief rivers are the Forth and Tay, the former receiving the Teith, Allan, and Devon, the latter the Tummel, Lyon, Isla, Braan, Almond, and Earn; whilst amongst uplands of the county are the Lochs Tay, Ericht, Earn, Rannoch, Lydoch, Katerie, Auchterarder, and Menteith. In the south rise the Ochils, with Dunnyatt (1375 feet) and Blairdenon Hill (2072); in the south-east the Sillaw Hills, with Dun-sinane (1012) and King's Seat (1225); and the Highland mountains are largely occupied by the Grampians, of whose forty-six summits exceeding 3000 feet may be mentioned Ben Lawers (with cairn, 4004), Benmore (3843), Ben-y-Gloce (3671), Schiehallion (3547), Ben Vorlich (3224), Ben Ledi (2875), Ben Vrackie (2757), and Ben Venue (2933). The soil is extremely varied, in places of great fertility—e.g., in Strathearn and in the Cars of Gowrie, which skirts the north side of the Tay's estuary; but barely a fifth of the entire surface is in tillage, the rest being pasture, woods, deer-forests, mountain, and desolate moorland, such as the Rannoch, etc. The woods cover nearly 100,000 acres; and the annual rental of the Perthshire deer-forests, grouse-moors, and rod- and net-fishings exceeds in some years £70,000. Ancient divisions were Athole (N.), Rannoch (NW.), Breadalbane (W.), Balquhidder (SW.), Menteith (S.), Perth (SE.), Gowrie (E.). Stirling (central). The county since 1885 returns two members, one for the eastern and one for the western division; and Perth itself is a parliamentary burgh. Other towns and villages are Aberfeldy, Abernethy, Auchterarder, Birnam, Blair-Athole, Blairgowrie, Callander, Comrie, Comar, Angus, Crieff, Doune, Dunkblane, Dunkeld, Pitlochry, Scone, and Stanley. The Roman camp at Ardclach is a famous antiquity; and Perthshire contains the battlefields of the Grampian, Tippelin, Killiecrankie, and Sheriffmuir; whilst it possesses memories of Bruce, Queen Mary, the Earl of Royston, Bob Roy, Burns, Scott, Lady Nairne, Wordsworth, and Queen Victoria. The mansions, which are very numerous, include Taymouth, Drummond, and Blair castles. Pop. (1861) 125,583; (1881) 142,166; (1891) 129,007; (1891) 120,184, of whom 14,150 were Gaelic-speaking.

See separate articles on many of the above-named places; also works by Drummond (1879), Marshall (1880), Hunter (1888), and Millar (1890).

Pertinax, HELVIUS, Roman emperor, was born, according to Dio Cassius, at Alba-Pompeia, a Roman colony of Liguria, August 1, 126 A.D. He received a good education, and, entering the military service, rose through the various grades till he obtained the command of the first legion, at the head of which he signalled himself in Rhedia and Noricum against the native tribes. In 179 he was chosen consul, aided to repel the revolt of Avitus in Syria, and was governor successively of the provinces of Moesia, Dacia, and Syria. The Emperor Commodus sent him to take the command of the turbulent legions in Britain, who against his will proclaimed him emperor; though the senate recalled him, and was appointed pro-consul of Africa, prefect of Rome, and consul (a second time) in 192. On the death of Commodus his assassins forced Pertinax to accept the purple, which with great hesitation he did; but, in spite of his promise of a large donation, he was unable to gain over the pretorian guard. His accession was, however, hailed with delight by the senate and people, who were rejoiced to have as ruler an able captain instead of a ferocious debauchee; and Pertinax encouraged his soldiers by an unparalleled display of lenity in his intention of carrying out an extensive series of reforms, having reference chiefly to the army, in which he hoped to re-establish the ancient Roman discipline. Unfortunately for his reforms and himself, he was overthrown by a band of the rebellious pretorians, two months and twenty days after his accession, and, disdaining to flee, was slain, and his head carried about the streets of Rome in triumph.

Perturbations, in Physical Astronomy, are the disturbances produced in the simple elliptic motion of one body by another about the same by the attraction of a third body, or by the perturbations of the principal body. Thus, for instance, there were no bodies in space except the earth and moon, the
April there is usually constant dryness on the coast, from June to September the sky is obscured for weeks by mist, sometimes accompanied by drizzling rain. The maximum temperature is about 78° in summer and 60° in winter. When it is hottest and driest on the coast it is mining heavily in the Andes, and the rivers are full. When the rivers are lowest, muds and gours, carrying a weight of about 100 lb. Alpacas have always been prized for their long and soft wool, and are tended with great care, being kept in large flocks. The other animals of the Peruvian Sierra are the guinea pig, the capybara, the chinchilla, a native dog, and a fox. The largest bird is the condor, and there is another bird of the culture tribe called deckonari. Partridges, called yuta, and plovers are met with on the lofty plateaus.

The large and handsome geese called huachinua and
hualatá, several ducks, a gull, flamingoes, and other wading-birds frequent Lake Titicaca and the banks of the rivers. In the valleys there are many kinds of finches, and a great pink-footed finch has been seen at a height of 12,000 feet above the sea. 

The Montaña is the region of tropical forests within the basin of the river Amazon, including the wooded slopes of the eastern watershed of the Andes. It will be called the subtropical portion of the Montaña. This part of Peru is traversed by great navigable rivers. Here the Marañón and Huallaga, after separate courses of 600 and 400 miles respectively, unite and flow eastward to the Brazilian frontier. At 150 miles from their point of junction they are increased by the waters of the Ucayali, a great navigable river with a course of 600 miles. The forests drained by the Marañón, Huallaga, and Ucayali form the northern portion of the Peruvian Montaña. The southern half is watered by streams flowing down from the eastern Andes in the Sierra sections of Cuzco and Titicaca, and forming the Madre de Dios, a great tributary of the Bolivian river Beni, which has not yet been fully explored. The whole length of the Peruvian Montaña, from the Marañón to the Bolivian frontier, is 800 miles. In the sub tropical portion of this work, coconuts (Cocos nucifera), which sometimes extend for a distance of 60 or 80 miles before they subside into the Amazonian plain, are very important products. This is the region of the quinine-yielding cinchona-trees, and of the coca (Erythroxylon coca), and here coffee and cacao are cultivated. From the forest-covered plains come india-rubber, sarsaparilla, and a great variety of useful and ornamental timber. The fauna of the forests is naturally much more numerous and varied than that of the Sierra. Among the larger mammals, the llama and the alpaca are the largest in South America, and other species. Rats of several kinds are numerous, and there are flocks of coatis. The Andean bear, called ceñuari, is found on the upper borders of the forests. The puma also roams over the higher slopes, where he has an almost undisputed hunting-ground. Lower down there are jaguars, and several kinds of wild cats. Squirrels and other rodents swarm, and the heavy tapir, called danta or gran bestia, reposes in the soft marshy lands. Deer frequent the open ground, and herds of peccaries traverse the forests. The chief game-bird is the large guan or curassow, and there are several pigeons. Spoonbills, ibis, cranes, snipe, and curlew frequent the lagoons, while parrots, toucans, and other birds of bright plumage are innumerable. Snakes abound among the dense underwood, frogs raise their far-sounding voices through the night, and insects swarm in myriads. But the knowledge of the fauna of the Peruvian forests is still very incomplete.

Productions and Commerce.—The chief crops of the fertile valleys on the coast of Peru are sugar, cotton, and grapes. The exportation of sugar amounted to 45,000 tons in 1889, but it was double that figure in 1879, previous to the disastrous war with Chili. Peruvian cotton is chiefly grown in the valleys of Piura and Ica, and is a perennial. In 1889 the quantity of cotton exported from Peru was 30,000 bales of 910 lbs. The sugar industry has been a profitable industry ever since the Spanish conquest, in several valleys on the coast, and also in the Sierra. Good wine is made at Pisco and Ica, and also a famous spirit from the grape, called pisco and licor. The yearly production of grape wine is 17,000,000 imperial gallons, and of spirits 5,280,000 imperial gallons. Rice of excellent quality is raised in the coastal valley of Lambayeque, and there are establishments for preparing it at Lambayeque and Ferreñafe. In 1889 the crop was 24,750,000 lb. Olives are grown in the Tambo valley near Arequipa, and before the Chilian war mulberries, silkworms, and cochineal were successfully cultivated. The rocky islets and barren deserts of the coast were once the scene of immense wealth to Peru, but are so no more. The exportation of Guano (q.v.) from the Chineha Islands began in 1846 and ended in 1872, the supply being exhausted; and the nitrates of Tarapacá were seized and annexed by Chili, as the result of the war. The staple product of the Sierras of Peru are silver and wool. The silver-mines extend along the whole length of the cordilleras, and are worked here and there; the great centre of mining industry being at Cerro Paseo. In 1877 the Cerro Paseo mines produced 1,457,392 oz. of silver, and there are others of equal value round Puno, in the south of Peru. In the above year the value of exported silver was £575,000; of copper, £330,000. Up till 1891 there were no later returns; in 1894 the total mineral output was valued at £450,000. There are rich gold-washings in the Caravaya province.

Mollendo is the principal port for the export of wool; but wool is also shipped from Salaverry, Paesamayo, and Chala. There are no reliable returns of the quantity and value. From the Montaña the exported products are cinchona and sarsaparilla. The exportation of cinchona (q.v.), 1874, was 604 lb.; in 1890, 1,000 lb. A quantity of sarsaparilla was exported in 1890, coffee of the finest quality, cacao, tobacco, india-rubber, sarsaparilla, and some other medicinal roots. Maize is also exported to Chili, and large quantities of wheat are imported from Chili and the United States.

Public Works.—The system of railways (911 miles in 1897) consists of several short lines in the coastal valleys—from 20 to 80 miles in length, constructed to bring the produce down to the seaports—with two long trans-Andean lines. The first of these, from Lima to Callao and the Port of Callao, and from Lima to Jania, is to be 136 miles long, and was commenced in 1870. It threads the intricate gorges of the Andes by a winding path along the edges of precipices, through tunnels, and over bridges that seem suspended in the air. It tunnels the Andes at an altitude of 15,645 feet, and the bridge of Verrugas (q.v.), finished in 1891 in succession to one destroyed by a flood in 1889, is 250 feet high, and spans a chasm 580 feet wide. Of this railroad 87 miles had been completed at a cost of £4,625,887. The other great line across the Andes connects the port of Mollendo with Puno on the shores of Lake Titicaca, passing through Arequipa. The summit is crossed at a height of 14,660 feet, and the line is 346 miles long. In 1874 steamers were first launched on Lake Titicaca. In order to supply the port of Mollendo with water a pipe has been laid alongside the line from Arequipa—for a length of 85 miles, discharging 433,000 gallons in twenty-four hours—the longest iron aqueduct in the world. The construction of these great public works, chiefly between 1868 and 1872, involved the finances of Peru in grave difficulties. Previously the debt mainly incurred during the war of independence, was £4,400,000, the interest of which was paid from the proceeds of the guano. But by 1872 the debt had been increased to £49,000,000, requiring an annual sum of £5,400,000 to pay the interest. The payment of this interest was made in 1873, but from 1874 interest had been paid since 1849. The financial difficulties culminated with the disastrous war with Chili, when the nitrates of Tarapacá, the chief resource of Peru, fell into the hands of the enemy. 

The People.—The Peruvian population is composed of the aboriginal Inca Indians, whose language, called Quichua, is still spoken in the Sierra. The Incas had attained to a high state of civilization before the arrival of the Spaniards. They cultivated many of the arts, and had some knowledge of astronomy. They had domesticated...
the llamas and alpacas, had brought under cultivation maize and quinoa, potatoes and many other edible roots, underground mining and the working of metals, and excelled as masons, weavers, potters, and farmers. They brought the science of government to a high pitch of perfection. The Incas composed songs and dramas; and as soldiers their skill and prowess enabled them to conquer conquerors. Throughout the centuries of oppression under Spanish rule have deteriorated the character of the Inca Indian, but he is still industrious and honest, and retains some of the virtues of his ancestors. The wild Indians of the Andes are not the Inca, and the Indian civilization has been reduced. The cultivation of the Inca period has also been reduced. The cultivation of the Inca period has also been reduced.

The department of Puno comprises the basin of Titicaca and the rich province of Caravaya in the Montaña. Its capital, on the north-western shore of the lake, owes its origin to the rise of silver mining in the surrounding hills. The other cities of the department are Lampa and Chucuito.

Church and Education.—When the Spanish conquests brought new ideas and beliefs. This destructive system was resolute and well organised, and was in great part successful. Education and literature were in the hands of an intolerant priesthood. The cruel Valverde murdered Bishop of Cuzco in 1554. The archbishop of Lima was murdered in 1541, and the bishoprics of Guanama, Arequipa, and Trujillo were added in 1612 and 1614. Swarms of clerics followed the bishops, numerous monasteries were founded, and an inquisitorial system of catechising and punishing penetrated into every village and hamlet in the land. Schools were established in the towns for the education of young Spaniards and half-castes; and the University of San Marcos at Lima, the most ancient in the New World, was founded in 1551. It had professorial chairs of medicina, philosophy, rhetoric, Latin, mathematics, and astronomy, and it produced men of ability in every branch of thought. The language of the Incas. In 1793 there were 313 doctors of San Marcos. The college of San Carlos at Lima, which still flourishes, was founded in 1770, and the school of medicine was established in 1792. At Cuzco the university of San Pedro was founded in 1565 by Viceroy, Prince of Esquilache, also endowed the college of San Borja there, for the education of noble Indians. At Arequipa the college of San Giovanni was founded in 1616, for teaching Latin and theology, and similar colleges were founded at Trujillo in 1621 and at Guanama in 1629. These universities and colleges produced historians and other writers of eminence, the best known in Europe being Dr. Peralta y Barreneu, who wrote Lima Fundada, and Leon Pino, the author of a well-known library. In later times, and after independence, Peru has produced many meritorious writers, including the learned Dr. Vigil, the antiquary Rivero, the historians Lorente and Palma, the geographers Paz Soldan and Uanune, the poets Marquez, Althea, and 'Juan de Arona,' and the biographer Mendiburu. Additional colleges have been established in the large towns, and numerous schools in the villages, within the last fifty years. Besides the university of Lima there are two lesser universities at Cuzco and Arequipa. There are high schools maintained by government in the capitals of the provinces (originally) compulsory for both sexes, and is free in the municipal public schools, yet but a fraction of the population has attended any school.

History.—From very ancient times there were agricultural communities in the Sierras of Peru, and finally in the art of weaving, and in the cultivation of peaceful. They had brought under cultivation, and the animals they had domesticated, are among the most important of the great antiquity of Peruvian civilisation. Eventually all the people of the continent became one empire, and the Incas, in the course of some five centuries, developed a highly centralised system of government. Civilisation never attained to such a height among any other of the indigenous races of America. The Incas attempted the administration of the coast of Peru, containing the celebrated ports of Lima, Chalca, Siema, and Tinta. The department of Puno comprises the basin of Titicaca and the rich province of Caravaya in the Montaña. Its capital, on the north-western shore of the lake, owes its origin to the rise of silver mining in the surrounding hills. The other cities of the department are Lampa and Chucuito.
tion of a purely socialist government, and their attempt was unsuccessful. The great Inca Huayna Capac died, after a long and prosperous reign, at about the same time that the Mapocho Peruwamo, a leader of the Mapocho Peruwamo, was executed. On his death there was a war of succession between his two sons, who had just terminated in favour of Atahualpa when Pizarro (q.v.) landed a second time and marched into the interior. Peru was soon overrun by the Spanish, and the beneficial rule of the Inca's came to an end. But at the time of the assassination of Pizarro the presentations of Las Casas (q.v.) respecting the cruel treatment of the Indians had obtained a hearing, and the "New Laws" were promulgated. The grants conceded to the conquistadores were not to be hereditary, all men who had been engaged in civil wars were to be deprived, and personal service from Indians was forbidden. Blasco Nuñez Vela was sent out to Peru as viceroy to enforce these reforms. He landed in 1544, and proclaimed the "New Laws." The Spanish conquerors were thrown into a state of exasperation and dismay, and appealed to Gonzalo Pizarro (q.v.) to leave his retirement and protect their interests. The result was that the viceroy was defeated and killed, and Gonzalo virtually became governor of Peru. But he was not recognized by the Spanish government, and the viceroyalty went to Chile. Gasca was despatched to Peru, with a commission to restore order. Gonzalo Pizarro was defeated near Cuzeo, and beheaded on the battlefield. Gasca reversed the humane legislation advocated by Las Casas, and made a nasty distribution of grants to his followers. The announcement of his awards caused much discontent, but Gasca hurriedly sailed for Spain in January 1550, leaving the country in a most unsettled state, in the hands of the four judges who were his colleagues. He had arranged that the Spanish viceroy of Peru and the Indian should be promulgated after he was safe out of the country. This gave rise to a formidable rebellion, led by Francisco Hernandez Giron. The judges made head against it, but it was not put down until two pitched battles had been fought, and Giron had been beheaded at Lima in December 1554.

The Marquis of Cañete arrived as viceroy of Peru in May 1555. His policy was to employ the unquiet spirits among the Spanish settlers on expeditions of discovery into unknown regions, and to treat the natives with liberality and justice. During the five years of his government he restored order among the conquerors, and established the heir to the Incas in a dignified retirement. But it was Don Francisco de Toledo, the viceroy from 1559 to 1580, whose legislation finally fixed the colonial policy of Spain in this part of the New World. He reversed the kindly treatment of the ancient dynasty which had distinguished the Marquis of Cañete, and unjustly beheaded young Tupac Amaru, the last of the Incas, at Cuzco in 1572 and beheaded his men. His legislation is well known in the system of the Incas. His elaborate code, called the "Libro de Tassas," was the textbook of all future viceroys. He fixed the amount of tribute to be paid by the Indians, exempting all males under the age of eighteen and over that of fifty from the tribute, assigning others to the different missions, assigning them magisterial functions, and the duty of collecting the taxes and paying the money to the Spanish officials. But he enacted that one-seventh part of the population of every village should be subject to forced labor, generally in the same year. This was called the Mitma system. It was the habitual infliction of the rules established by Toledo, and the abuse of the Mitma, which caused all the subsequent misery and the depopulation of the country. Compliance with the continual demand for treasure from Spain, a demand which was insatiable, was incompatible with humane treatment of the people. For more than a century the Indians perished, and Peru toiled and died. At length their sufferings became intolerable. They rose as one man in the autumn of 1780, and a descendant of the Incas, taking the revered name of Tupac Amaru, placed himself at their head. After a long and formidable resistance the insur- rrection was subjugated, and the last of the Incas was put to death under circumstances of revolting cruelty. But he did not die in vain. In his fall he shook the colonial power of Spain to its foundation. From the cruel death of the Inca Tupac Amaru may be dated the rise of that feeling which ended in the expulsion of the Spaniards from South America. Some of the demands of the Incas were conceded soon after his death. He was the foremost pioneer of the independence of Peru. The desire for liberty among Peruvians of Spanish descent had its birth in Lima; but Lima was the residence of the viceroy. Here the power of Spain was concentrated. Consequently it was in the more distant colonies of Buenos Ayres, Caraccas, and Chili that insurrectionary movements first broke out and that independence was first secured.

At length a fleet under Lord Cochrane (see DUN-DONALD) equaled the Spanish fleet, and the campaign of the Argentine General San Martin to Peru with troops, and the independence of the land of the Incas was proclaimed at Lima on the 28th of July 1821. Another liberating force, from Columbia, under General Bolivar, embarked at Guayaquil, and when he arrived at Lima, in September 1822, San Martin retired. The Spanish viceroy, La Seru, with his army, retreated into the interior, and the patriots followed on his heels. On 9th December 1824 the decisive battle of Ayacucho was fought, the battle of the century, and the independence of Peru was freed. They were brought to a free republic. Bolivar and his Colombians left the country in 1826, but it was eighteen years before the government became settled. In August 1829 General Gamarra, a native of Cuzco and a hero of Ayacucho, was elected president of Peru, but at the end of his term of office there were troubles which culminated with an attempt to form a Peruvian Confederation under General Santa Cruz. This was defeated by Peruvian mal-contents, aided by a Chilian army, the cause of Santa Cruz destroyed, and the documents were examined after the decisive battle of Yungay on January 20, 1839. Gamarra again became president, the confederation was dissolved, and a constitution was proclaimed. But Gamarra fell in a deplorable war with Bolivia, and the contentions of his officers caused a succession of civil wars until 1844.

At length a man arose who restored peace to the distracted country. Ramon Castilla was a native of Tarapaca, and was a veteran of Ayacucho. He was brave as a lion, prompt in action, and beloved by all. At the end of the war he was elected president of Peru, and he held the office from 1844 to 1850, and again from 1856 to 1866, during a long period of peace. He was elected constitutional president of Peru in 1844, and ten years of peace followed. Castilla commenced the payment of interest on the foreign debt in 1849. A revised constitution was promulgated in 1856, and the leagues were reformed, and the constitution of 1856 was promulgated in office in 1862, and died in 1866. The next important event was the election of Colonel Balta. This president held office from 1862 to 1872, during which time public works were undertaken on a gigantic scale with the aid of American capital. Don Manuel Pardo, a scholar and a man of letters as well as a statesman, was the first civilian president. He held office from 1872 to 1876, and inaugurated a policy of retrenchment. But it was too late to save the credit of the state, and the payments of
Chronicle of Calahue, and the Memorias de los Vireyes; also the more recent works of Stevenson, the Chilian Amir, González; the Memoirs of General Miller (London, 1858), the Autobiography of the Earl of Dundonald, and the great biographical work of General Mendiburu; for the war with Chili, narratives from the Chilian point of view by Arana and Miranda, from the Peruvian by Paz Soldan, and the present writer's History of the War between Peru and Chili (1883). For the geography, the Geografía del Perú, by Paz Soldan, and the present writer's History of Peru (Chicago, 1892).

Peru, (1) a city of Illinois, at the head of navigation on the Illinois River, 110 miles by rail WSW. of Chicago. It is a foundry, a plough-factory, and several ice-houses. Pop. (1900) 6863. — (2) Capital of Miami county, Indiana, on the Wabash River, and on the Wabash and Erie Canal, 75 miles by rail N. of Indianapolis. It mills and factories produce woolens, bagging, furniture, basket-ware, &c. Pop. (1900) 8403.

Perugia, a city of Italy, stands (1706 feet above sea-level) on the right bank of the Tiber, 11 miles E. of the lake of Perugia (anc. Lake Trasimene), and 127 miles by rail N. of Rome. It is surrounded with walls pierced by gates (one of them very old). The broad Corso, which contains the handsomest edifices, unites two squares, in one of which stands the Gothic cathedral of St Lawrence, dating from the end of the 13th century, and adorned with many paintings, carvings, &c. The church of St Dominic (1362) contains the tomb of Pope Benedict XI, by Giovanni Pisano, and stained windows (1402); the remarkable church of St Peter (11th century) has granite pillars, and pictures by Raphael, Perugino, and the masters of the 15th century; besides a number of noble and picturesque monuments. In the cathedral square stand also the Gothic municipal palace (1281), with the valuable art gallery, especially rich in productions of the Umbrian school; the great fountain, adorned with statues by Niccolo and Giovanni Pisano; the statue of Pope Julius III (1555), described in N. Hawthorne's Marble Faun; and the old money-changers' bull (1453-57), decorated with some of Perugino's best works. In the vicinity of the city a number of Etruscan tombs were discovered in 1840; they contain several rich bronzes, bronze statues and bronzes, and many lustrous ornaments. Pop. (1881) 17,365. Perugia, the ancient Perusia, was one of the twelve Etruscan republican cities. It was besieged and captured by the Romans in 310 B.C., and again in 40 B.C., and by Tullia (349). At different periods it was the residence of thirteen pontiffs elected to the popes, especially after the middle of the 16th century; at other times it was independent, though in the power of native despots. In the 16th century it became the centre of the Umbrian school.

For the history of the Inca and their civilization, see the works of Cieza de Leon, Molina, Balboa, Garcia de la Vega, Montesinos, and Acosta, all, except Molina, translated into English Society; also Rivero's Antiguedades Peruanas (with Von Tschudi, Vienna, 1851), of which an English translation appeared afterwards at New York; and the histories of Roderic Romeu, Lobo, Presvy, Helpes, and Wissow (vol. I.), and the travels of D'Orelliny, Squier, Wiener, and Reiss and Stübel. For the Conquest, see, besides Robertson, Prescott, and Helpes, the narrative of Xaviera, and the works of Hakluyt, See, and the writings of Herrera, Gimara, Zanate, Pedro, Pizarro, and Fernandez. For the period of the vicereys, see Figuero's Life of the Marquis of Cadiz, the
of painting. In 1890 it was made a part of the kingdom of Italy.

Perugia, Lake of. See Trasimene Lake.

Perugino, a celebrated Italian painter, whose real name was Pietro Vannucci, was born at Citta della Pieve in Umbria, in 1446, but established his residence at Perugia, where he painted pictures of the most important subjects, and also studied under Verrocchio at Florence. He executed important works, no longer extant, at Florence, Perugia (1475), and Cercato (1478). At home, whether he went about 1483, Sixtus IV. engaged him to paint the ceiling of the Sistine Chapel. The frescoes painted for 'Christ giving the Keys to Peter' is the best of those still visible—other than being destroyed to make way for Michelangelo's 'Last Judgment.' During his next sojourn at Florence (1486–99) he had Raphael for his pupil. Here he was fined for rivalry of the dissecting of the soul. In a somewhat too fond of money, repeating his works and leaving much of the execution to pupils. At Perugia (1499–1504) he adorned the Hall of the Cambio, with the assistance of Raphael and other pupils; but after 1500 he was visibly declined. In his next years, he went to Rome (1507–12), and there he painted frescoes for the Stanza di Luna, was the fresco relieved when Raphael was commissioned to substitute his works for those formerly painted on the walls and ceilings. The new school, with Leonardo da Vinci, Michelangelo, and Raphael, was now in the ascendant, and Perugino's popularity waned. He was again at Perugia in 1512, and painted a number of pictures there. He was painting frescoes in a church at Castello di Ponteuggio, near Perugia (one of which frescoes is now at South Kensington), when he was seized by the plague, of which he died in 1524.

Perugino's art was religious, though he is said by Vasari (biased in all regards by Michelangelo's contempt for Perugino) to have been an open debauchee of his senses. In his figures, very uniquely drawn, there is a peculiar tenderness of expression verging on faintheartedness; his execution was delicate, his colour admirable. But he is not remarkable for originality or intensity.

Peruvian Bark. See Cinchona.

Pescador Islands. See FORMOSA.

Pescchia, a fortress of Italy, a member of the Quadrilateral (q.v.), stands partly on an island in the Lake of Garda, 14 miles by rail W. of Verona and 77 E. of Milan.

Besides a strong citadel and an arsenal, there is a fortified camp. The fortress has played a prominent part in the warlike events which have taken place in North Italy, especially after the Napoleonic wars began down to 1859. Pop. 1655.

Peshawar, or Peshawur, a town of India, 184 miles from the north part of the district of Peshawar at 190 E. by S. of Kabul, and 276 by rail NW. of Lahore. Although a frontier town and occupying a strategic position of the utmost importance, its only defences are a mud wall and a small fort; but 2 miles west of the city are the cantonments, with a garrison of six regiments, a battery of Royal Artillery. The population in 1891 was 84,191, including the cantonments. Peshawar is the seat of extensive commerce between Afghanistan and India; gold, silver, lace, hides (all four from Bokhara), horses, mules, fruits, woolen and skin coats (all five from Kabul) being exchanged for English piece-goods, wheat, salt, rice, butter, oilseeds, oil, and sugar.—The district has an area of 2564 sq. m. and a pop. of 592,674; the division, an area of 8831 and a total pop. of 1,189,462.

Pesilto (Syriac pšlštd, 'the simple'), the Syriac Vulgate. See BIBLE, Vol. II. p. 129.

Pessimism is the doctrine that on the whole the world is less fortunate than good; and it necessarily means that the world is the worst possible of all conceivable worlds, as the fact of its being the verbal opposite to Optimism, the term employed to describe the Leibnitzian philosophy, would seem to imply; it means simply that the world is so bad that it would be better if it did not exist. Pessimism presents itself in a twofold aspect—(1) as a settled attitude of mind or permanent mood of feeling, and (2) as a philosophical system. The former springs out of the contemplation of the antagonism that exists in the world between natural laws and moral laws, between the world as it actually is and the world as it ought to be; it is the outcome of reflection, and is largely conditioned by individual temperament. Thus it is coeval with the dawn of conscious intelligence, and early found fit literary expression. The problem of the existence of evil, the connection between suffering and sin, is the burden of the ancient Hebrew Book of Job; and the Jewish thinker who wrote Ecclesiastes rings the changes upon the nothingness of life, and sums up his plaint in the hopeless refrain, 'Vanitatem humiliavit, saeculum est illud, nihil est vanitas.' Different forms of the same temper of mind are given utterance to with more or less of moral indignation in Innocent III.'s De Mineria Humanae Conditionis, and the satirical works of Juvenal and Carlyle and others. The same 'world-sadness' (Weltenschmerz), though expressed in more personal and passionate language, colours deeply the poetry of Omar Khayyam, Leopardi, Heine, and Byron; and the negation of the problem, 'Is life worth living?' forms an undercurrent in much of our best modern literature. But in the pessimistic temper, culminating in the persuasion of the nothingness and vanity of human life, has had more than an individual expression; it has entered deeply into the substance and structure of two of the world's greatest religious beliefs—viz. Christianity and Buddhism. The Christian and Buddhist worlds derive the doctrine that this earthly life is a vale of tears and woe, and that its pleasures and joys are illusory, being always accompanied with sin and suffering and evil, from which he can only escape by fixing his hopes upon a life in the world to come. Buddha's practical teaching (see BUDDHISM) turns in great part upon the desire to escape from the sorrows of life and the deceptive illusions of existence (mayâ). But here, in this latter point, the pessimistic
mood assumes something of a philosophical character. It also enters, though principally as an unconscious element, into the philosophical doctrine of the life of the soul, as Neoplatonism, in that they regarded man’s sensual (sense) nature as opposed and inferior to his intellectual. The medieval mystics (Eckhart) combined the religious with the philosophical tendencies of the mood that despiseth the earth, but not in a conscious, deliberately philosophic way. But it is only in the more recent times that pessimism has been elaborated into a philosophy or complete theory, in the systems of Schopenhauer (q.v.) and his successor, E. von Hartmann (q.v.). Schopenhauer is generally considered to be the father of philosophical pessimism, for he regards the world principle as an omnipotent, blindly struggling and striving Will, which is incapable of satisfying itself or of delivering itself from its eternal cyclic misery. Hartmann formulates as world principle the Unconscious, whose primal error, for which it eternally stumbles in the endless mercy of the world, was its kindling—just as Schopenhauer’s Will did—a light for itself in the brain, or the consciousness of organised life. Both philosophers build on the pain and misery and struggle which they see everywhere in the world, from earthwise position and the far movements to the farthest ones, through the endless struggle of organisms for existence to the acce suffering exhibited in the many forms of human passion, and chiefly of all in exalted passionate love or sexual desire (Romeo and Juliet, or Kabinett und Liebe of Schiller); and begins for the individual only in the far movement of the terrible, irrational, or non-logicial cosmic agency. It is extremely difficult to state shortly the metaphysical grounds of pessimism; they are far from being merely superficial, and may be said to be rooted in the old antitheses between nature and man, and between the individual and the world, which modern science has shown us what a small twig human life is on the great tree. Both Schopenhauer and Hartmann lay a firm hold on the fact (emphasised especially by Schopenhauer in opposition to Hegel) that not only the idea of the world, but our man must be used in replanning the world, but also Force, Impulse, Will, Strife. Thus in a sense they represent the substitution of the scientific or cosmic attitude towards the world for the merely introspective attitude of a Descartes or a commonsense thinker. It is not, of course, in the least to be assumed that what we call ‘naturalism,’ as opposed to speculation or supernaturalism, leads to pessimism, mental and spiritual facts being just as ultimate as chemical protoplasm. The full force of pessimism lies in the assertion that all the ends and aims of life are illusion, that life, in fact, brings only illusion; the illusion of illusions being man’s innate and inevitable belief that he is born to be happy and to have pleasure. There are here two main contentions: (1) All ends are illusory, even cosmic ends, for nothing is ever attained, as is always the case, seeing that there is no world—that which holds it together—is strife and change. Pessimism, that is, really denies teleology, as Darwinism does, in the old sense of the term. (2) In the case of the individual life there is excess of means and means and ends is said to be one of the most common causes of misery and pain. But there is no reason for despising the realisation of certain ends because there always arises a limitless number of new ends to be realised; of course we do not wish to limit the world process. Pessimism thus really comes to stake its case on the individual, which (let us say) to a certain extent we do immediately know. The natural man wants to fill infinity, to gratify all his desires, to embrace in himself all the ends of the world, and because he cannot do this, but even fails to get immediate ends gratified, he votes the world excerable. The pessimists in the end do not escape the all-embracing human standpoint of anthropo-centricism. To them the conscious thought is not, in the first place, to avoid the errors of metaphysics and ‘transcendental idealism.’ They examine man, and what they find to be true of man they predicate of the world: he ‘measures’ all things—is the microcosm. Still, we must concede that, if to man the world brings only illusion, if both the ends and the means of the world are illusion, the central position, then, of pessimism inevitably comes to be that living beings have as matter of fact an excess of pain over pleasure.

To this position the psychologist answers: (1) That pleasure and pain are not things that can be balanced. Both have an inclination to wear out, and they come also to a certain point of balance: feeling, which, though itself a constant element of experience, is only one element; and what we do as matter of fact measure and are conscious of is the amount of change or transition in our feeling, there being of course no absolute measure of amount of pleasure or painful feeling. (2) Even if by the help of memory and calculation, and observation and reflection (for there is really enormous difficulty in the matter), we allow ourselves to think of sums of pleasures and sums of pains (there are writers who say the phrases are the purest nonsense, and that if one attempts to measure such things—no ‘hedonistic calculus’ or universal method of measuring pain against pleasure, can be fixed upon. (3) Even supposing we had an estimate of pleasures and pains, it is not psychologically legitimate to regard feeling of any kind as the end of things. (4) There are actions which have a final value apart from their pleasurable character, although also as matter of fact the attainment of pleasure or pain. (5) It is only by absurd and never by individual index or measure (i.e. whether normal or abnormal), while there are absolute measures of action in the ends or things accomplished. (6) There are actions which have a final value apart from their pleasurable character, although also as matter of fact the attainment of pleasures or pains. (7) It is only by absurd and never by individual index or measure (i.e. whether normal or abnormal), while there are absolute measures of action in the ends or things accomplished.

If we ask the pessimist if there is any freedom or release from the ‘bondage of man,’ we are answered: (1) The light which the Unconscious Will has kindled for itself in the brain of man (pessimism has of course pronouncedly naturalistic side) confers on us at least one advantage; employing this light, we may for brief moments pause, and survey with pity the awful slavery and strife of life. In a word, artistic perception, the insight into things of the man of genius, of the exalted intellect, is freedom: art, asceticism, quietism, orientalism, and suchlike. (2) To the individual suicide is to be deprecated as the name of the selfish assertion of the Will to be happy, it is to be hoped that some day the human race will be educated enough to see the contemptible character of life, and let us say that suicide is one of the highest forms of the bowing wilderness of life. (2) While individual suicide is to be deprecated as the name of the selfish assertion of the Will to be happy, it is to be hoped that some day the human race will be educated enough to see the contemptible character of life, and let us say that suicide is one of the highest forms of the bowing wilderness of life. If we demur that it is, then, only the few who can be saved, we are told
that the lot of life is one; my life is the same as that in the plant or the planet, and there is, as matters at present stand, not the least fear that the 'will to live' will die out with the death of my life in quietism, agnosticism, and mysticism.

Then, contrary to Rousseau, I also say: (1) That it is not necessary to have a theory of the world in order to make action possible; no one lives because he chooses to live, but because he must, and this apart from the question whether a theory of life is attainable or already attained. (2) That it is not the children of this world who measured altogether by the expectations or equations of the individual as to his own happiness, and that therefore pessimism is overthrown with the rejection of empirical Hedonism or the theory of ethical conduct that makes happiness the end of the world (3) Pessimism has done good in rousing up the illusions to which an acceptance of the Hedonistic or the Epicurean ethical leads in theory and practice; it might be held in fact to give a negative account of man's perfection as consisting not in happiness for happiness' sake, but in the self-seeking self formed apart from man's desire or aversion to them, to the self-seeking self everything is foreign and negative, and also to the perfection-seeking self the ends of appetite and desire are illusory. The various forms of pessimism—the practical, the theoretical, the theogical, the positivistic—all of value as provisional accounts of the ethical end. The unconditioned sympathy with all forms of life inculcated in modern pessimism is a valuable contribution to ethical and class, history, and it appears to them that the world is incomprehensible. Both, in fact, tend to erect our ignorance of the world into a positive principle—the Uncon- scientious; but this is an old metaphysical fallacy. The world which the individual does know—i.e. the small sphere of it he knows—is not a sphere in which he cannot realise himself, but in Kantian language a moral kingdom; it will be able to educate his outer sphere. Thus it has been indicated how in a sense the pessimists are not to be held down to an Epicurean theory of morals, although they take their start from that.

BIBLIOGRAPHY.—Scobener’s chief work is the World as Will and Idea (Eng. trans. 3 vols. 1883-86). His ethic is contained chiefly in the fourth book, on the Ascension and Denial of the Will to Live. The appendices contain many exceedingly readable and vivid presentations of the main points of his system, so do many of the sections of the Parerga und Paralipomena. which has a high historical value. See translations of these in Mr. T. B. Saunders’ ‘Schopenheuer’s Series (1890 et seq.), Hartmann’s views are expounded in Philosophy of the Unconscious, which is also translated into English (1884). An admirable short account of his system in mind is that of Dr. A. Drews (Ed. v. Hartmann’s Philosophy, 1890). E. Wallace’s account of pessimism in the Westminster Review (1876) is eminently instructive, and has chief reference to Hartmann. An introductory treatise is also that of A. Tannert, Der Pessimismus und seine Gegner (1873). Mr. Sully’s Pessimism (1875) is an admirable and careful psychological criticism of pessimism. In addition, there is a large list of pessimistic literature. As an introduction to pessimism some account of Leibnitz’s philosophy ought to be read, and after Voltaire’s vigorous and drastic criticism (in his Essai sur le Prince) it is necessary to understand what Schopenheuer meant when he called optimism a ‘wicked and otiose shallow philosophy.’

The religious aspect of pessimism is touched on in an essay in Benthall’s Essays in Philosophical Criticism (1883), and also in Professor Tylor’s Modern Theories (1884).

Pestalozzi

Pestalozzi, Johann Heinrich, educational theorist, was born at Zurich, 12th January 1745. Eccentric, quixotic, eager to be an adjuster of social wrongs from his youth, he sought to realise his aims through educating the young. He shares with Émile great successes in mind. The honour of conceiving a method which is the cornerstone of all sound theories of primary education. From his day onward two ideas of education co-existed—the older one, applicable to the children of the classes; his, applicable to the children of the poor; the form of education was always improved by an encroachment of the latter upon its traditional domain. Pestalozzi, living during the period of the French Revolution and the wars of Napoleon, found in his disturbed country, in the misery inflicted by war, opportunity for the display of self-sacrifice, devotion to the oppressed, and that unselfish love of the children of the very poor which especially distinguished him. Illiterate, ill-dressed, a bad speaker, and a bad manager, Pestalozzi was unfit for the everyday business of life, and all his undertakings resulted in personal failure, there was no place in the admiration of Europe, and calling forth down to the present day in many countries, more especially in Germany, a crowd of disciples, who have carried out the principles of their master with great zeal. Thus it was that Pestalozzi’s works, even with the world, Pestalozzi’s personality was instinct with a loving sensibility; he awoke men to a sense of responsibility to childhood, and ushered the 19th century upon the stage of history as the educational age par excellence.

Pestalozzi’s life is one of likeness. Believing justly in the moralising virtue of agricultural occupations and rural environment, he chose a farm upon which to dwell with his collected waifs and strays as a father among his own. The farm Neuhof, in the canton Aargau, stranded on a faulty economic history after a five years’ struggle (1790), Pestalozzi withdrew then from practical life, to think out the educational problem. His Evening Hours of a Hermit was the first fruit of his meditations, and develops the following thoughts: before undertaking to educate men, learn to know him; the method whereby to educate man should be founded upon his own nature; in his nature are hidden the forces that draw out his faculties, exercise them; exercise, the instrument of education, connects the wants of our nature with the objects that satisfy them; rejoice in the fullness of your strength, make your education answer to your needs and to the inner call of your soul. Then came a social novel, Leonard and Gertrude, in four volumes. The former is a drunken stone-mason, the latter his wife, and a good one; the scene, a village given over to corruption. At last the minister, the schoolmaster, Gertrude with a few peasant-women, set about the reform of the village. This story created much attention, and was followed by a long period of literary activity on the part of its author. In 1798 he plunged into a rival school at Stanz. The picture he there makes of a moneyless, helpless, homeless lover of children, gathering homeless, helpless, children around him in an old conven in a township ruined by war, and set upon by a hostile and ignorant peasantry, is a picture of a noble picture. But that picture has proved too hard for Pestalozzi. At the end of eight months this establishment was broken up.

He next wended his steps to the people’s school at Berthoud (Burgdorf), in canton Berne, only to be ejected from it. On his return at the age of fifty-five, by the jealous and bigoted senior master. He knew then the bitterest pangs of poverty, and had even to keep away from church for want of clothes. In partnership with others, and
PESTALOZZI

under the patronage of the Swiss government, he opened an experimental school of his own, still at Berthoud. While there he published "How Grammar and Arithmetic Must Be Taught," and more fully developed the book. It is the recognised exposition of the Pestalozzian method, and sets forth that the development of human nature should be in dependence upon natural laws, with which it is the business of every good education to comply; in order to estimate them, we must learn first to understand nature, its general processes in man, and its particular processes in each individual; observation, the result of which is a spontaneous perception (intuition) of things, is the method by which all objects of knowledge are brought home to man.

This last affirmation, containing in essence the whole theory of so-called intuitional education, is the corner-stone on which the German Volkschule ("folk-school") is built, the guiding principle of numberless books written for children, and the subject of much controversy.

In 1805 Pestalozzi moved his school to Yverdon, where he drew upon the eyes of all Europe; in spite, however, of this his greatest moment of popularity and promise of worldly success, he entered upon a course of mistakes that led him to the downfall of his hitherto unexpected success. Deviating from the field of primary teaching, he applied his method in a large secondary school for the sons of notable Europeans attracted by his fame. His old incapacity in practical affairs brought the school down step by step till it closed in 1825, and Pestalozzi, aged eighty, distracted by the enmity of some of his former colleagues, sinking under difficulties of his own making, an object of mingled pity and respect, addressed to mankind the Song of the seven, a short educational prayer, and withdrew to Brugg (Aargau) where he died, 1827. Pestalozzi's books are all written in German.

See the article 'Pestalozzi' in the last edition of Quick's Biographers (1890); Morf, Zwei Biographie Pestalozzi (4 vols. 1864-89); De Guimpes monograph, translated by John Bascan (1880); Biografie Pestalozzi (New York, 1873); Leonard and Gertrude (Eng. trans. 1825); and, above all, Pestalozzi, Etude Biographique (1890), by J. Guillaume.

PESTH, or more correctly BUDAPEST, because since 1873 it has been united with Buda (Ger. Gutenbrunn, properly, is the capital of Hungary, and next after Vienna the third city of the Austrian-Hungarian empire. It stands on the Danube, Buda on the right bank and Pesth on the left, 173 miles by rail SSE. of Vienna. The two towns are connected by three bridges, a chain bridge (designed by Clark Brothers of England in 1842-49), 1280 feet long, uniting the busiest quarters of the two; another, built in 1827-75, a little higher up (1555 feet long); and a railway bridge near the southern end of both towns. Pesth is essentially a modern place, the growth principally of the last century. Its many fine streets and squares, the magnificent quays (3 miles long) beside the Danube being the favourite promenades; the buildings are chiefly noteworthy for their substantial appearance and frequently large size. Among other works may be enumerated the Jewish synagogue (the handsomest place of worship in the city); the parish church (1500) and the new Cathedral basilica (1831-68); the national museum (after 1850), containing collections of pictures, ethnography, natural history, mineralogy, botany, natural sciences, and plaster casts, and a library of 400,000 volumes and 63,000 MSS.; the academy of sciences (1809), containing a small collection of valuable old pictures, another of engravings and drawings, and a library of 60,000 volumes; the university (1635), established first at Tyrman, then at Buda in 1777, and lastly at Pesth in 1873, with 250 lecturers and 4000 students, equipped with excellent scientific laboratories, &c., and having nearly 200,000 volumes; the central library (1870-74), barracks, military academy (1872), slaughter-house (1870-72), industrial and commercial museums; and the magnificent new parliament houses and the palace of justice, completed for the millennium celebration in 1896.

Whilst Pesth stands on a plain, Buda straggles over small steep hills, and is backed by vine-clad slopes. It is a much older town, its central features being the castle in the citadel (1749-71), with the chapel of St Sigismund, in which are preserved the bones of King St Stephen; the church of the Benedictines; the bishop's palace, and the castle of St John (13th century); the palaces of the Honved ministry, the premier, and Archduke Joseph; the monumental tomb of G. Balas (1543-48), a Turkish saint; and the national lunatic asylum (1869-68).

Both towns are exceptionally well provided with baths, which are supplied both by the Danube and by numerous natural springs of mineral waters. Some of these last—Hunyadi János, Rakoczey, &c.—are exported in large quantities in bottles. The Artesian well in the castle and the waters already referred to under Artistic WELf. The water-works of Pesth were planned and built by the English engineer Lincle in 1868. Both towns possess an unusual number of philanthropic institutions, such as hospitals, asylums, &c. There is in Pesth a polytechnic (in Buda, 1840-72), besides the faculties of chemistry, architecture, and engineering, attended by 620 students, who are taught by 70 lecturers. A great number of learned and scientific societies flourish; and there is a music academy. The people are gay and fond of amusement, especially horse-racing (in the Aradi and other parks), and there are two beautiful public gardens, one in Pesth, the other on Margaret Island in the Danube, just above the town. The squares and streets of both Pesth and Buda are adorned with many statues of celebrated Hungarians. The following figure will show the extraordinarily rapid growth of Budapest: pop. in 1813 was 36,153; in 1833, 63,145; 1857, 116,683; 1869, 270,476; 1881, 530,767; 1891, 491,938. The last summation includes 11,000 military. The figure for 1881 embraced 75,794 in Buda and 67,253 in Pesth; amongst these were included 71,000 Jews. Budapest is the first manufacturing town of Hungary. The making of machinery and agricultural implements, wagons, and ships, the manufacture of spirits, tobacco, beer, gold and silver wares, cutlery, stationery, glass, and innumerable other articles, the distilling of corn, washing of wool, and printing are all prosecuted on a large scale; there is here a small-arms factory. But the commerce is even more important: immense quantities of corn are brought into the town, and exported and other products. To these are added wines, spirits, and oils-seeds and agricultural seeds, hemp, tobacco, plums (from Bosnia and Servia), honey and wax, bacon, hides, feathers, timber, coal, and manufactured wares are the principal articles of the extensive trade. Vast numbers of swine are fattened and killed in large yards just outside Pesth.

The Romans had a military colony on the site of the modern Buda. In the 13th century there existed here a flourishing German town, Old Buda. This was destroyed by the Mongols in 1241: but it continued to exist, and was regarded as the capital of the country from the middle of the same century down to its capture by the Turks in 1527. From 1541 down to 1686 the Turks held Buda, though it was besieged
half a dozen times by the Austrians. Pesth meanwhile was reduced to a heap of ruins; and it did not begin to recover until the first quarter of the 18th century. A century later it was rapidly outstripping its twin-sister Budin.

There are German books on Pesth by Hevesi (1873), Kincses (1892), Helesch (1880); and one in Hungarian, by Gerlóczy and Dulaško (3 vols. 1879).

Pestilence. See Epidemic, Black Death, Cholera, Plague, Sweating Sickness.

Petal. See Flower.

Petard, an instrument for blowing open the gates of a fortress, demolishing palisades, &c., consisting of a half-cone of iron filled with powder and ball; this was firmly fastened to a plank, and the latter and provided with hooks to allow of its being attached securely to a gate, &c. The petard, which was lighted by a slow-match, was superseded by the use of powder-bags. Large petards contained as much as 13 lb. of powder. See Bomb, and Shell.

Petavius, Dionysius, the name by which the great sixteenth theologian Denys Petan is usually known. Born at Orleans, 21st August 1583, he studied at Orleans and Paris, became a teacher in the university of Bourges in 1602, in 1605 entered the order of Jesuits, and 1621 was made professor of Theology in the university of Paris. This post he held long, but in 1640, retired and devoted himself to the completion of a remarkable series of works in philology, history, and theology. Of his 49 works among the best known are editions of Syneces (1611) and Epiphanians (1622); De Doctrina Temporum (1627); Tribulum Chronologicae (1628); Rationarium Temporum, an outline of universal history (1634); and De Theologica Dogmatibus, a history of doctrines (1641–50; new ed. by Thomas, 8 vols. 1864 et sequ.); besides polemical works against Grotius and Salmasius.

He died in Paris, 11th December 1652.

Petchenegs. See Russia, Vol. IX, p. 43.

Petchora, a large river of Russia, rises on the western slope of the Urala, flows north through the eastern parts of the governments of Vologda and Archangel, then south-east for 150 miles, and finally sweeping northwards into an estuary 30 miles wide and full of islands, falls into the Arctic Ocean, after a course of 1720 miles. It is navigable by boats for upwards of 700 miles. The country through which the river flows is thinly peopled and quite uncultivated; dense forests extend on both sides, and the character of the scenery is wild, sombre, and melancholy. See Seboohn's Siberia in Europe (1881).

Pechelia. This term is given to spots of a dusky crimson or purple colour, quite flat, with a well-defined margin, and unaffected by pressure, which closely resemble flea-bites. These spots result from a minute extravasation of blood beneath the cuticle. They occur mostly on the back, at the bend of the elbow, and in the groin. They indicate an altered state of the blood, and are characteristic of the disease called purpura; but are often symptomatic of very serious diseases, as of typhus fever, plague, septic, &c., &c. They likewise occur in very severe cases of small-pox, measles, and scarlet fever, when their presence must be regarded as indicative of extreme danger.

Peter, St, apostle, named originally Symeon (Acts, xiv. 14) or Simon, was 'of Bethsaida' (John, i. 44) on the Lake of Galilee, but during the public ministry of Jesus had his house at Capernaum, where he was one of the Four who brought his Mother and Brother to Jesus. Andrew, the household, including his mother-in-law and probably children (Mark, ix. 33, 36), his father was called John (John, i. 42; xxi. 15, 16, R.V.) or Jonas (Jonah), and the name by which he himself is known in Christian history is the Greek translation of that given him by Jesus (Cephas, Græcisised form of Aramaic kepha, meaning 'rock' or 'stone', Gr. Petra, nasse. Petros). He was a fisherman by occupation, and together with his brother Andrew was actually engaged in the pursuit of his calling on the Sea of Galilee when Jesus called both to be his disciples, promising to make them 'fishers of men.' For this invitation they had been prepared by previous acquaintance, formed perhaps for the first time when they were attending the baptism of John the Baptist (John, i. 40–42), and they both accepted it without hesitation. For the incidents recorded in the life of Peter as a disciple reference must be made to the four canonical gospels. It is plain, especially from the Synoptics, that he was regarded by Jesus with particular favour and affection. In many respects he was indeed an ideal disciple, warmly attached to his master, quick (on occasions at least) to apprehend new ideas, and ardent, energetic, and fearless in following them out.

This is seen most clearly at that most important crisis in the life of Jesus. The first time Peter appeared to the first to see and say 'Thou art the Christ, the son of the living God' (Matt. xvi. 16–18); and it is not without reason therefore that Matthew significantly heads his list of the apostles with 'the first, Peter.' The testimony of the twelve, and the leadership among the twelve Peter continued to hold. In the earliest extant account of the resurrection (1 Cor. xv. 5) it is stated that the risen Christ appeared first 'to Cephas, then to the twelve;' and in the Epistle to the Galatians the apostle Paul tells us that his first errand to Jerusalem after his conversion was 'to visit Cephas' (Gal. i. 18). In the Acts of the Apostles Peter was the first mover in the election of a new apostle in the room of Judas Iscariot; he was the spokesman on the rest of the day of Pentecost, and also when they were brought before the council; he was the judge who condemned Ananias and Sapphira; and, along with John, he was sent from Jerusalem to the Samaritans converts that they might receive the Holy Ghost; and he was the first to baptise a Gentile convert, taking a Frankish in the council or conference at Jerusalem, the result of which, though its events are somewhat differently related in Gal. ii. 1–10 and in Acts, xv. 4–29, was his acceptance of the policy of conciliation between the contending Jewish and Gentile parties. The date of this council cannot be accurately fixed, but no recent scholar has placed it earlier than 47 A.D. or later than 53 A.D. He afterwards came to Antioch and for a time worked in harmony with Paul, but ultimately the famous dispute arose (Gal. ii. 11–21) which in conjunction with other causes led to the termination of Paul's ministry in that city. Peter, however, seems to have remained in Antioch, and was afterwards regarded as the founder of its church. His subsequent history is very obscure. On any theory of the authorship of I Peter that text was written by the bearer of belief that his missionary activity extended as far as to Pontus, Cappadocia, Galatia, Asia, and Bithynia; and, on one interpretation of 1 Peter, v. 13 (which, however, has little probability), he also laboured in Babylon. Then the sufferer martyred is clearly John, xii. 18, 19, and is confirmed by the unanimous voice of ecclesiastical tradition; as to the manner of it, we have it on the authority of Eusebius (H.E. iii. 1, interpreted by some as resting on Origen) that he was impaled or crucified with his head downwards, and a tradition from the end of the 2d century invariably mentions Rome, and this also is most probably implied in the vague phraseology of Clemens Romanus (I Ep. v. 4). Another circum-
stance that makes somewhat for a residence, how-

er ever, brief, of Peter in Rome is his probable connec-

It may be taken as certain that Peter was not in

the Epistle to the Romans was written, if the 16th chapter of that epistle is to be accepted

genuine; and it is almost equally evident that

have been there when Paul was writing to the

Thus the comparatively late tradition which assigns him a continuous hishopic

ultimately to Peter in Rome in 16 A.D. to 67 A.D.

must be regarded as unhistorical. If he came at

all to Rome it can only have been after 64 A.D.

Of the duration of his stay we have no means

of judging.

The dispute between Protestants and Catholics as to

whether Peter was ever at Rome began as early as at

least as 1530, when Vehelin (Velenus) published his De-

monstratio contra Romanj papam primatum ssumendum; it was

answered by Bishop Fisher of Rochester in his Consilio

cum iimmiuisue Abbeclie Feloni. For the arguments cur-

rent in that and the following century, see Spanheim,

Disertatio de Acta profetise Petcri apostoli in urbe

Romana (1679). In later times the question has been the sub-

ject of numerous and diverse controversies; but not with

the same motives or entirely on the same grounds. The

recent discussions began with Baur, who has been fol-

lowed by Lipsius, Zeller, and others in a complete denial of

the apostolic authorship for the 'Peter Legend,' among

those who have sought to vindicate for it some

basis of truth may be named Crocher, Wieseler, Ewald,

Hilgenfeld, and Renan. For the apocryphal Acts of Peter and

Theodore, and the conclusion of the apostolical

Gospel according to Peter and the Revelation of Peter,

found in 1866-87 at Akhmim in Egypt, was published in

1892 by J. A. Robinson and M. R. James, and by others.

(2d ed. 1871); Dillingen's Petrus et the Church (3d Eng. ed. 1871); and Johann Schmid, Petrus

in Rom, where the literature on both sides of the question

is very fully given. On the whole subject of the history

and legends connected with the name of Peter the import-

ant work of Lipsius, Die apokryphen Apostelgeschichten

und Apostellegenden (1883-90), ought to be consulted.

Peter, THE EPISTLES OF, constitute two of the

seven canonical writings of the New Testament

which towards the beginning of the 3d century began to be spoken of as 'catholic' epistles.

Eusebius (H.E. iii. 3) tells us that 'as to the words of the apostle Peter, the first

is acknowledged as genuine. For this was used and

used by the fathers in their writings as an undoubted

work of the apostle. But that which is called the

second we have not indeed understood to be embar-

bled with the sacred books, yet, as it appeared

useful to many, it was studiously read with the

other scriptures.' Among the earliest witnesses to

the antiquity of the first epistle the first usually

cited is Clemens Romans, who is supposed to be

quoting from it when he uses the phrases 'this nar-

sing /right,' or 'clearly covereth a multitude of

sins.' It was known to the author of The Shepherd

of Hermes, and to Basilides; Papisa was acquainted

with it; and Polycarp used it largely; but it is not

mentioned as canonical in the Muratorian Canon.

Coming to the internal evidence, it claims to have

been written by the apostle Peter, by the hand of

Silvanus, from 'Babylon' (the elect who are

sojourners of the Dispersion in Pontus, Galatia,

Cappadocia, Asia, and Bithynia,' and in substance

it is a practical exhortation to a godly conversation,

particularly by reference to all constituted authorities,

in the practice of the dominant virtues and in

patience under persecution. The elders are ex-

cluded to feed their flocks, the younger to obey,

and all to be sober, watchful and constant in the

faith, resisting their adversary the devil. Through-

out it abounds with echoes of Pauline expressions

and modes of thought; in particular the exhorta-

tions contained in Rom. xii. 1-xxii. 14 have been

reproduced virtually verse by verse. This circum-

stance of its dependence on the Pauline writings is

one of the views which it was called 'Petrine' as

Baur, Schwengler, Keim, Lipsius, Pfeiderer,

Weizäcker, Hilgenfeld, Holtzmann) who fix its

date at some period after 112 A.D. in the reign of

Trajan, by whom formal proceedings were first

instituted against Gnosticism. They had confirm-

ation of their view in the use of the name 'Balthasar'

for 'Rome'; a use that seems to have been first

introduced by the author of the Apocalypse. The

second epistle claims to be by 'Symeon Peter'

(i. i). the associate of Paul (iii. 15), and a witness

of the resurrection (i. 17, 18); the expression 'four

apostles' (iii. 2, R.V.), on the other hand, is held by

many critics to be a confession of the author's non-

apostolicity. The evidence supplied by itself as to

its authorship has been variously interpreted, some

affirming and some denying that its thought, ex-

pression and vocabulary exclusively show that it

cannot have been written by the author of 1 Peter.

Its relation to the Epistle of Jude is also still under

discussion, but the weight of opinion seems to be

in favour of the priority of the latter. The external

evidence as to its existence down to the end of the

century is of very uncertain value. It is quoted quite

by Eusebius as saying that even in his day there

was some doubt as to whether it was by Peter.

The genuineness of both epistles is argued for (to

mention only two out of many weighty names) by Sal-

mon (Introduction to the New Testament) and by Weiss

(Entstehungsgeschichte, R. V.), the opposite view is taken

by Holtzmann (Entstehung, 1886), who may be consulted

for references to other authors, many of whom accept

the first epistle while rejecting the second. There are

comments or diffusions of Petrus and of Football

by Fritzsche; the latter is also edited by Hutter

(Meyer's Kommentar; Eng. trans., Lillie, and

Plumptre. Leighton's Practical Commentary on 1 Peter

is one of the classics of English theology.

Peter the Cruel. See Pedro.

Peter the Great. Peter I, Alexander-

dreievich, emperor of Russia, was the son of the

Dvortoiy by his second wife, Natalia

Narishkina, and was born in Moscow, June 7, 1672.

His father died in 1676, leaving the throne to

his eldest son, Feodor, Peter's half-brother.

This prince, however, died in 1682 without issue,

after naming Peter as his successor, to the exclu-

sion of his youngest brother, Ivan, who was weak-

minded. This step immediately provoked an in-

surrection of the 'stratelli' or militia, fomented by

Ivan's sister, the grand-duchess Sophia, who, after

a carnage of three days, succeeded in obtaining the

coronation (On. 1682) of Ivan and Peter as joint

rulers, and her own appointment as regent. Upon

Ivan's death the following autumn, the

the regency he was considered to have been

greatly neglected, but after this time he had the good

fortune to fall under the guidance of Lefort (q.v.),

a Genevese, who initiated him into the sciences and

the arts of civilization, and by showing him how

much Russia was behind the rest of Europe, influence

the whole of his future career. Lefort also formed a

small military company out of the young men of noble family who attended

Peter, and he rendered the czar himself all the while

as a model of rigid discipline. This course of train-

ing in all probability saved Peter from the mere

savage descent which his brutal and

passionate disposition and indomitable energy

inclined him to be; it also protected him from the

jealousy of his half-brother, the regent Sophia, who

though in the ascendency was discouraged in military exercises, studies,

and amusements. She, indeed, soon feared his

power, for Peter, contrary to her wishes, married

(1689), by his mother's advice, Eudoxia Feodorovna

by her error, for Peter, contrary to her wishes, married

(1689), by his mother's advice, Eudoxia Feodorovna
PETER THE GREAT

89

Lopukhin; and in October of the same year called upon his sister to resign the government. In the ensuing contest Peter was at first worsted, and compelled to flee for his life; but he was joined by the foreigners in the Russian service, with Patrick Gordon (q.v.) and Lefort at their head; and the situation, in the case of the contest, and was shut up in a convent, whence, till her death in 1704, she did not cease to annoy him by her intrigues. On October 11, 1689, Peter made his public entry into Moscow, where he was met by Ivan, to whom he gave the nominal supremecy, and had him increase the power for himself. Ivan only enjoyed his puppet sovereignty till 1696.

Peter's first care on assuming the government was to form an army disciplined according to European tactics, in which labour he was greatly aided by Gordon and Lefort, both of whom were military men. He also laboured to create a navy, both armed and mercantile; but at this period Russia presented few facilities for such an attempt, for she was shut out from the Baltic by Sweden and the Dutch, from the Black Sea by Turkey, and from the White Sea and the Arctic Ocean, by the solitary port of Archangel, available for the Russian navy. Peter, thinking the possession of a portion of the Baltic and of a free intercourse in that of accessible seaboard and port, declared war against Turkey, and took (1696) the city of Azov at the mouth of the Don, after a long siege. Skilled engineers, architects, and artillerists were now invited from Austria, Venice, Prussia, and Holland, to improve the Russian art of war; and by Peter the army further improved both in arms and discipline. Many of the young nobility were ordered to travel in foreign countries, chiefly in Holland and Italy, and to take special notice of all matters in connection with shipbuilding and naval equipment; others were sent to Germany to study the military art. Peter was eager to see for himself the countries for which civilisation had done so much; and, after repressing a revolt of the streitzi and dispersing them among the various provinces of Russia, he went to the Netherlands, in the train of an embassy of which Lefort was the head. In the guise of an inferior official of the embassy he visited the three Baltic provinces, Prussia, and Hanover, reaching Amsterdam, where, and subsequently at Zaandam, he worked for some time as a common shipwright, and to his practice of shipbuilding and kindred trades he added the study of astronomy, natural philosophy, geography, and even anatomy and surgery. On receipt of an invitation from William III. he visited England, and for three months, spent partly in London and partly at Deptford,laboured to assimilate all sorts of useful information. While in England he received the honorary degree of D.C.L. from the university of Oxford. He left England in April 1698, carrying with him English engineers, artificers, surgeons, artisans, artillerists, &c., to the number of 300, and next visited Vienna, for the purpose of inspecting the emperor of Austria's army, then the best in Europe. He was about to visit Venice also, when the news of a formidable rebellion of the streitzi recalled him to Russia. General Gordon had already induced the revolt, and Peter finally broke up the institution that had given him so much trouble. The Empress Eudoxia, who was suspected of complicity in the conspiracy, which had been the work of the old Russian or anti-regular, was arrested, and shut up in a convent, and the great reforms were begun. Peter put the press on a proper footing, caused translations of the most celebrated works of foreign authors to be made and published, and established naval and other schools. Ordinary arithmetic was first introduced, accounts having been previously kept by means of the Abacos (q.v.). Trade with foreign countries, which was formerly punished as a capital crime, was now permitted, or rather, permitted. A petition of the merchants, insisted upon. Many changes in dress and manners, and in etiquette were introduced and enforced on the people at large. Even the organisation of the national church could not escape Peter's reforming zeal.

In 1700 Peter, desirous of gaining possession of Carelia and Ingrin, provinces of Sweden which had formerly belonged to Russia, entered into an alliance with the kings of Poland and Denmark to make a combined attack on Sweden; but he was shamefully defeated at Narva, his raw troops being wholly unable to cope with the Swedish veterans. Peter was by no means disheartened, but quietly appropriated a portion of Ingrin, in which he laid the foundation of the new capital, St Petersburg, 27th May 1703. Great inducements were held out to those who would reside in it, and in a few years it became the Russian seat of war for the Baltic. In the long contest with Sweden the Russians were almost always defeated; but Peter saw that these reverses were administering to his troops a more lasting and effective discipline than the victories of the Dutch could confer on any other way. He had his revenge at last, in totally routing the Swedish king, Charles XII., at Pultowa (q.v.), 8th July 1709, and in seizing the whole of the Baltic provinces and a portion of Finland in the following year. His success against Sweden helped much to consolidate his empire and to render his subjects more favourably disposed towards the new order of things. After reorganising his army he prepared for strife with the Turks, who, at the instigation of Charles XII. (then residing at Bender), had declared war against him (see TURKEY). In this contest Peter was reduced to such straits that he despaired of escape. But, according to a somewhat doubtful tradition, the finesse and ability of his mistress, Catharine, extricated him from his difficulties; for she, in disguise, was received at Baku, with the utmost vigour. In 1712 his marriage with his mistress, Catharine (see CATHARINE I.), was celebrated at St Petersburg, and the offices of the central government were transferred to the new capital. His arms in Pomerania and Finland were victorious, and in 1712 the latter province was completely subdued. In 1716-17, in company with the czarina, he made another tour of Europe, this time visiting Paris, and returned to Russia in October 1717, carrying with him quantities of books, paintings, statues, &c. It was soon after this time that his son Alexei (q.v.), who had opposed some of his father's reforms, was condemned to death, and died in prison—apparently through having been repeatedly tortured. Many of the nobles who had been implicated in his troubles were arrested; and the nobility in general deplored his unseemly death. In 1721 peace was made with Sweden, which definitely ceded the Baltic provinces, Ingrin (now government of St Petersburg), and a portion of Finland with the islands off the coasts. In 1722 Peter issued a decree, in order to open up the Caspian Sea to Russian commerce, and secured three Caspian provinces along with the towns of Derbend and Baku. For
the last years of his life he was chiefly engaged in beautifying and improving his new capital and carrying out plans for the more general diffusion of knowledge and education among his subjects. In the autumn of 1724 he was attacked with a serious illness, and he died 8th February (28th January o. l.) 1725. Catherine succeeded him. The 'Testament of Peter the Great,' inciting the Russians to aim at domination in Europe, is a forgery, based probably on Lessar's Progrès de la Puissance Russe (1697), and, it may be, inspired by Napoleon.

See Russian Lives by Golovin (30 vols. 1797); and Ustralov (1863); English Lives by Barrow (new ed. 1881) and Schuyler (2 vols. 1884); and for a vindication of the authenticity of the 'Testament,' W. J. Thoms in the Nineteenth Century (1879).

Peter II. (Alexeevitch) of Russia, was the sole male representative of Peter the Great, being the son of the unfortunate Alexei (see above), and was born 23rd October 1715 at St. Petersburg. On the death of the Czarina Catharine I. he ascended the throne (1727). Menshikoff, his guardian, affianced one of his daughters to the youthful czar, but his power was overturned by the Dolgorouki family; and the czar was seized with smallpox, and died at St. Petersburg, January 29. 1730.

Peter III. (Ferdorovich) of Russia, grandson of Peter the Great (being the son of his eldest daughter, Anna, and Ivan Petrovitch, wife of the Duke of Holstein-Gottorp), was born at Kiel, 29th January 1728, and in 1742 was declared by the Czarina Elizabeth (q. v.) her successor on the throne of Russia. From the time of his being publicly proclaimed heir he lived at the Russian court; and in obedience to the wishes of the czarina he married Sophia-Augusta, a princess of Anhalt-Zerbst, who on entering the Greek Church assumed the name of Catharina Alexeevna. Peter succeeded Elizabeth on her death in 1762; and his first act of authority was to restore East Prussia to Frederick the Great (whom he admired extravagantly), and to send to his aid a force of 15,000 men. He also recalled many of the political exiles from Siberia. When arranging in 1762 a campaign to take Sleswick from Denmark a formidable conspiracy, headed by his wife, and supported by the principal nobles, broke out against him—a conspiracy which originated in the general discontent at the czar's liberal innovations, the preference he showed for Germans, his indifference to the national religion, and his servility to Frederick the Great. The czar was twice deposed and his crown: his wife Catharine was proclaimed as Catharine II. (q. v.); and Peter, who optimally abdicated, was strangled by Orloff and some of the conspirators on the 17th July 1762.

Peterborough, a city partly in Huntingdonshire, but chiefly in Northamptonshire, the latter part being the left or north bank of the river Nene at the edge of the fen-country. 76 miles N. of London and 42 N.E. of Northampton. Here, at Medeshamstede, in 655, the Mercian thane Saxulf founded the great Benedictine abbey of St. Peter, Paul, and Andrew, which, destroyed by the Danes in 870, was restored in 990, plundered by Hereward in 1069, and again burned down in 1116. Its noble church, the cathe-

dral since 1541 of a new diocese carved out of that of Lincoln, was built between 1118 and 1298, and thus, whilst essentially Norman, offers every variety of architecture down to the Perpendicular. It is 471 feet long, by 292 across the transept, and 81 high. The Early English west front (c. 1200-22) consists of three mighty arches, and 'is perhaps,' says Freeman, 'the grandest conception for a single feature which mediæval architecture has produced, a Greek portico translated into Gothic language.' Noteworthy also are the flat painted wooden ceilings of the 12th century, the portrait of 'Old Scarlett' the sexton (1496-1594), the blue slab inscribed 'Queen Catharine, A.D. 1536,' and the grave for twenty-five years (1587-1612) of Mary Queen of Scots. In 1643 Cromwell and his troops dined here. Balls to monuments, stained glass, and cloisters. In 1883 the fine central tower was condemned as unsafe; but it has been lovingly rebuilt, and in 1890 the cathedral was reopened after restoration. Of the abbots may be mentioned Ernulf, Bishop of Rochester (1115); and of the twenty-seven bishops, Lloyd and White the nun-jurors, Richard Cumberland, Archbishop Mgee of York, and Mandell Creighton the historian. Paley was a native. Two ancient gateways, the bishop's palace and the deanery (once the abbots' and prior's houses), and the chancel of a becket chapel (now a museum) make up the remaining

Peterborough Cathedral—West Front.

objects of interest. A training college for schoolmasters (1864), a grammar-school, the town-hall (1671), the corn exchange (1848), a cattle-market of five acres (1867), and the bridge over the Nene (dating from 1140, but in its present form from only 1872) may be mentioned. Peterborough is an important railway centre, has manufactories of agricultural implements, and carries on a large trade in malt, coal, farm-produce, &c. Incorporated as a municipal borough in 1874, it has returned two members to parliament from 1547 till 1885, and since then one. Pop. (1841) 6059; (1881) 22,984; (1891) 25,172.

See works by Gunton (1868; new ed. 1825), Britton (1828), E. A. Palae (1849), Davys (3rd ed. 1863), Sweeting (1869), and Poole (1881).
PETERBOROUGH

PETERBOROUGH, chief town of Peterborough county, Ontario, on the Otonabee River (here crossed by six bridges), 82 miles by rail N.E. of Toronto. It exports lumber and agricultural products, and manufactures flour, woollens, farming implements, machinery, furniture, canoes, &c.

Peterborough, Charles Mordaunt, Earl of, was born in or about the year 1638. All particulars of his boyhood, even to the place of his education, seem to have been lost. The first definitely recorded event in his life is his voyage as a volunteer in Sir John Narborough's expedition against Cadiz in 1652. He was a prominent engineer in his army. In 1655 he went into exile in Holland, in the course of which he learnt how to command, and, as it were, was educated. He returned to England in 1657, and joined his father, John, first peer of that title, who owed his services in assisting to bring about the Restoration, having died in 1675.

In the military operations which afterwards married Carey, daughter of Sir Alexander Fraser, and in 1678 started on another maritime expedition, this time apparently in the capacity of a passenger. Returning after a year's absence, he again visited the extremities of his father's dominions, and again sailed with the fleet sent under Lord Plymouth for the relief of Tangier. On his return to England he began to take an active part in politics, identifying himself with the extreme Whig party throughout the whole of the three or four eventful years which followed the Glorious Revolution, and was a leading member of the Whig Opposition of the old school. He was suspected by both parties, in which restless agitator had pinched himself. At the accession of James II. Mordaunt became a prominent parliamentary opponent of the first minister, and one of the chief agitators of the court of the early reign of King William. Indeed he went at once so fast and so far as to press upon William of Orange a premature scheme for the invasion of England, which princely with his usual cool judgment rejected. After the Revolution he entered the House of Lords. He was an extreme and active Whig, but it was probably as much his zealous anxiety to supplant William's ministers suspected ofJacobitism as to combat Jacobite designs themselves that led to his embroilment in those intrigues arising out of the Assassination Plot, and the Fenwick trial, which ultimately resulted (January 1697) in his committal to the Tower. He was liberated in less than three months, and for several years thereafter he seems to have played no prominent part in public affairs.

In the war of the Spanish succession broke out, and in 1705 Peterborough (for by his uncle's death he had succeeded to that title shortly after his release from imprisonment) was appointed to the command of an army of 4000 Dutch and English soldiers, which he proceeded to Ypres, and there to begin the extraordinary campaign which has made his name famous in history. After successfully resisting the solicitations to attack the city which were addressed to him by the Prince of Hesse-Darmstadt, fresh from the capture of Gibralatar, he was joined by the English, and was sent to the Spanish throne, for whom the allies were fighting. Peterborough succeeded by a pretended retreat in surprising and capturing the strong fort of Monjuich on the south side of Barcelona, from which position of vantage he soon managed to reduce the city. The Catalan towns one after another declared for Charles; Gerona, Tarragona, Tossa, and Lerida opened their gates to him. In his conquest of Barcelona he marched southward in the depth of winter and driving back his emperor, reached Valencia early in February 1706. Meanwhile an army under the Duke of Anjou, the Femen claimant to the throne (afterwards Philip IV.), and Marshal Tessé had entered Catalonia, and was closely pressed by the Barcelonians. About the same time blockaded by a fleet under the Count of Toulouse. Hurrying back to the scene of his former exploit, and seeing that it was from the side of the sea that the town must be relieved, Peterborough threw himself on board one of the ships of the English squadron, took command in virtue of his commission, which gave him supreme control over the British forces at sea as well as on land, sent his orders to the admiral, and drove Toulouse and his fleet from before the port. This success was followed by the raising of the siege, the capture of Barcelona, and the splendid successes of Peterborough on the east coast, Galway, the British commander on the Portuguese frontier, advanced into the heart of Spain, and in June entered Madrid. Peterborough's eyes were set on marching from Valencia, whither he had now returned, and to effect a junction with Galway, but the archduke dallied irresolutely at Barcelona. Precious time was lost, Berwick rallied his forces, and compelled Galway to evacuate the capital, and when at last Charles advanced and summoned Peterborough to join him, it was too late. A plan formed by him for the recovery of Madrid was rejected, and in disgust he obtained permission to depart for Genoa to raise a loan on the Spanish revenues. Returning with success from his mission, he acted for some time as a sort of adviser to his military successors in Spain, but his imperious temper seems to have unfulfilled him for anything but supreme command, and his differences with Lord Stanhope and others led to his recall in March 1707.

His career thenceforward till his death at Lisbon on 25th October 1735 is interesting only to the student of letters and not to the politician. He was, as is well known, an intimate friend of Pope, with whom he was in constant communication almost up to the last day of his life, and whose genuine esteem for him may be inferred from the somewhat theatrical exterior which he presented to the world there lay qualities which justly endeared him to his friends. In 1722 he was, it is said, privately married to the famous singer Annaesia Robinson, but the lady was not publicly acknowledge as his countess till shortly before his death. Recent military criticism has made an elaborate endeavour to show that Peterborough's fame as a conqueror rests wholly on a basis of imposture, and that the whole credit of his conquest of Valencia must be distributed among others. This extreme view, however, has been shown by Mr Stebbing in his judicious and impartial monograph to be untenable. His verdict is that the figure of the hero remains much where it was, though its pedestal may have been somewhat lower.

See the Memoir by Russell (2 vols. 1887), and Stebbing's Peterborough (English Men of Action series, 1890).

PETERHEAD, a seaport and burgh of barony of Buchan, Aberdeenshire, on a peninsula, 32 miles by road, but 44 by a branch-line (1862), N.E. of Aberdeen. The town, which burned in 1599, was afterwards rebuilt in a regular plan, but clean and largely built of the celebrated 'Peterhead granite,' whose reddish
variety is so much used for monumental purposes. The Keiths, Earls Marischal, were superiors of the place till the rebellion of 1715, when the Old Pretender landed here, and after which their forfeited estates were purchased by the Edinburgh Merchants. Little is known of Argyle, and the improvements are owing. Of Marshal Keith (q.v.) a bronze statue was presented to the town in 1899 by King William of Prussia; and the market-cross, a granite Tuscan pillar (1833), bears the arms of the Earls Marischal. The public buildings (1836 to 1881), the town hall (1858), with a spire 125 feet high; the parish church (1803), with one of 118 feet; the free library and museum (1891); the academy (1846); and convict-prison (1859). Industries are woollen manufacture, boat-building, and granite-polishing. Peterhead was made a head-port in 1553. From 1788 it gradually became the chief British seat of the seal and whale fisheries, until in 1832 it sent out 30 ships; but since then there has been a great decline. At present Peterhead is chiefly important for its great herring fishery, which employs hundreds of boats, and which during the herring season brings some 5000 persons to the place. The south harbour was commenced in 1773, and the north harbour in 1818, a canal being formed between them in 1850; whilst a new harbour was formed north harbour commenced under the Acts of 1873 and 1876. Their three basins, hewn out of the solid rock, together cover about 22 acres, and have cost £300,000; but all three are as nothing compared with the great harbour of refuge, the works for which, designed by Sir John Coode, were commenced in 1866, and are to be completed in 1921 at a cost of £746,000. In the neighbourhood are the ruins of Inverugar, Ravenscraig, and Bodin castles, all strongholds of different branches of the Keiths; Buchan Ness, the most easterly point of Scotland, with a lighthouse (1827); and the Mullers of Lindhead (q.v.). Since 1838 Peterhead has united with Elgin, &c. to return one member to parliament. Pop. (1801) 3264; (1831) 7293; (1871) 19,922; (1891) 12,226.

See Peter Buchan's Annals of Peterhead (1819), besides his 7 vols. (1793) and Arisbuth (1815).

Peterhof, a palace of the Emperor of Russia, on the southern shore of the Gulf of Finland, 18 miles W. of St Petersburg, was built by Peter the Great in 1711, contains a fine collection of paintings, and is surrounded by beautiful parks and gardens. It is the model of those at Versailles, with cascades, terraces, and summer-houses. The town of Peterhof has 14,296 inhabitants.

Peter Lombard. See Lombard.

Peterloo Massacre, the name popularly given to the dispersal of a large meeting by armed force in St Peter's Field, Manchester, Monday, August 16, 1819. The assemblage, consisting chiefly of labourers of operatives from different parts of Manchester, called to discuss the question of parliamentary reform, and the church, on open hustings, was occupied by 'Orator' Hunt (q.v.). The dispersal took place by order of the magistrates; several troops of horse, including the Manchester Yeomanry, being concerned in the affair. Eleven persons (men, women, and children) were killed, and some 600 wounded. St Peter's Field is now the site of the Free-trade Hall. 'Peterloo' was a name suggested by Waterloo.

Peter Martyr, the patron saint of the Inquisition, a Dominican of Verona, who, for the severities exercised in the exercise of inquisitorial functions, was in 1292 slain at Conegliano, in the interests of an inquired populace. His death formed the subject of a masterpiece by Titian, destroyed by fire at Venice in 1687.

Peter Martyr (Ital. Pietro Martire Vermigli), Reformer, was born in Florence, September 8, 1500, entered at sixteen the order of the canons regular of St Augustine at Fiesole, studied at Padua, and became abbot of Spoletto, and later prior of San Fosfero, but soon fell under the suspicions of the Inquisition, and had to flee to Zurich (1542). At Strasbourg he was welcomed by Imer, and made professor of the Old Testament. In 1547 he came to England on Cranmer's invitation, lectured at Oxford on 1 Corinthians and Romans, and took an active part in the great controversy of the day. Mary's accession drove him back to Strasbourg, now grown too Lutheran for his tastes, and at length in 1555 he repaired to Zurich, where he died, November 12, 1562. His admirable Locci Communes was printed at London in 1575. See the study by C. Schmid-Francken, Zurich, 1881.

Peter Martyr Anglerus, historian, was born in 1450 at Arezzo, on the Lago Maggiore, of an ancient family belonging to Anghera, obtained a footing at the court of Ferdinand and Isabella in 1487, and rose to high ecclesiastical preferment in Spain. He was ultimately named Bishop of Jaén, and died at Granada in 1525. He wrote De Orbe Novo (1516), giving the first account of the discovery of America; De Legatione Bavonicensis (1516); and Opus Epistolarum (1530). See Berreys, Petrus Martyr Anglerus et sein Opus Epistolarum (1896).

Petersburg, the third city of Virginia, on the south bank of the Appomattox River, 23 miles by rail S. of Richmond. The falls above supply water-power for foundries, cotton, flour, and paper mills, and especially tobacco-factories. Petersburg is a well-built place, and contains a fine park. In the campaign of 1864 Grant, failing to take Richmond, was repulsed in several attacks by General Beauregard, with heavy loss. Pop. (1900) 21,810.

Petersburg. See St Petersburgh.

Petersfield, a market-town of Hampshire, 20 miles NNE. of Portsmouth by rail. Till 1832 it returned two members, and then till 1885 one. Pop. (1861) 8781.

Peter's-peece (denuros S. Petri), the name given to a tribute offered to the Roman pontiff in reverence of the memory of St Peter. From an early period the Roman see had been richly endowed; but the first idea of an annual tribute came from Anglo-Saxon England. It is ascribed by some to ius (721 A.D.), king of Wessex, by others to Ofla of Mercia, and by Lindard to Alfred the Great. It was extended to Ireland by Henry II. The tax consisted in the payment of a silver penny by every family possessing land or cattle of the yearly value of 30 pence, and it was collected during the five weeks between St Peter's and St Paul's Day and August 1. The tax, also called Rome-see, varied greatly in amount, but continued to be paid with intervals till the reign of Henry VIII. By Gregory VII. it was sought to establish it for Rome, and traces of a similar payment appear also in Denmark, Sweden, Norway, and Poland. This tribute differed from the payments of the feudal kingdoms, such as Naples, Aragon, and England under the reign of John. The tribute practically ceased at the Reformation. The pope having suffered a considerable loss of revenue since the revolution of 1848, an effort was made in several parts of Europe to revive the
payment of Peter's pence, not as a tribute but by the collection of free-will offerings. In some countries, as in Portugal, it was universal, and since the total annexion of the Papal States to the kingdom of Italy the tribute has been largely increased in France, Belgium, England, and Ireland. In 1877, on occasion of the jubilee of Pius IX., the payment amounted to £900,000.

**Peter the Hermit**, the apostle of the first crusade, was born and a native of Amiens, where he was born about the middle of the 11th century. He served some time as a soldier, became a monk, and is usually said to have made a pilgrimage to the Holy Land before 1094, when he began the preaching of the crusade. He failed in his first attempt, and leave such a mark on history. But it should be noted that Hagemeyer in his monograph *Peter der Erzmütig* (1880) denies that Peter was ever in Palestine till he went with the crusaders, and asserts that the scheme of a crusade originated with the pope, not with the hermit. The article CRUSADES gives an account of his preaching, its results, and of poor Peter's faint-hearted attempt at desertion during the siege of Antioch. After the end of the crusade he returned to Europe, and founded a monastery at Huy in the Loire department. He died 115. His remains were translated to Rome in 1634.

**Peter the Wild Boy** was found in July 1724 in a wood near Hanhœ in Hanover; ‘he was walking on his hands and feet, climbing up trees like a squirrel, and feeding upon grass and moss of trees.’ He was taken to George L., brought over by him to England in 1726, and placed under the care of the celebrated Dr Arbuthnot, who had him baptised ‘Peter.’ He was fond of music, but could never be taught to articulate more than ‘Ki Sho,’ ‘Qui Ca,’ and ‘Hom Hen,’ for ‘King George,’ ‘Queen Caroline,’ and ‘Tom Tom,’ the last of the Hertfordshire farmers with whom he lived after 1737. He would sometimes ramble away, on one occasion as far as Norwich, so was provided with a brass collar inscribed ‘Peter the Wild Boy, Broadway Farm, Berkshire.’

Lord Monbodho visited him in 1782, and in his *Origin of Language* describes him as only 5 feet 3 inches high, now about seventy years of age, quite tame, bearded, and fresh and healthy. But on the farmer’s death Peter took to his bed, refused food, and in a few days died, in August 1785. See *Notes and Queries* for 1857, and worked for a while.

**Peterwardein**, one of the strongest fortresses in the Austrian dominions, is situated in a marshy, unhealthy locality on the right bank of the Danube, 44 miles by rail N.W. of Belgrade, and is connected with Neusatz opposite by a bridge of boats. Pop. of town, 3605. The most ancient part of the defences, the so-called ‘Strange Tower’, is built on a rock of serpentine, which on three sides rises abruptly from the plain. The fortress was held by the Turks from 1526 to 1687. In 1688 the fortifications were blown up by the imperialists, and the town with some 10,000 people abandoned to the sword of the Turks; but at the peace of Passarowitz (1718) it remained in the possession of the emperor. Here, on 10th August 1716, Prince Eugene obtained a great victory over the Grand Vizier Ali. The Hungarians were compelled to yield the fortress to the Turks in his inspection 1749.

**Petiole.** See LEAF.

**Pétion de Villeneuve, Jérôme**, a prominent figure in the French Revolution, was the son of a procureur at Chartres, and was born there in 1753. He was practising as an advocate in his native city when he was elected in 1789 its deputy to the *Tiers État*. An ardent republican and fluent speaker, he quickly became popular, although essentially windy, verbose, and of mediocre understanding. He was a prominent member of the Jacobin Club, and as ‘Pétion the Tyrant’ was the ally of Robespierre the Incorruptible. He was sent along with Baronne and Latour-Maubourg to bring back the fugitive royal family from Varennes, and in the execution of this commission he acted in a brutal and unfeeling manner. He afterwards advocated the decapitation of the king, the establishment of a popularly elected regimen, and along with Robespierre received, 30th September 1791, the honours of a civic crown. On the 14th of November he was elected mayor of Paris in Baily’s stead, the court favouring his election to prevent that of Lafayette. On 10th October the mob seized the mob and the atrocious September massacres both fell within his year of office. He became the first president of the Convention, and was made ridiculous as ‘roi Pétion’ through Mannel’s proposal to give the president the same authority as the president of the United States. On the triumph of the Terrorists Pétion’s popularity declined, and he cast in his lot more and more with the Girondists, having become a habite Madame Roland’s salon. Like them he voted at the king’s trial for death, but with delay of his own motion and against the Convention. He was elected to the first committee of general defence in March 1793, and on 12th April he headed the fatal because unsuccessful attack on Robespierre. Proserbed among the twenty-two, on the 2d of June, he escaped to Caen, and on the failure of the attempt to make arraignments against the Convention fled to the Gironda with Guadet, Bazot, Barbaroux, Salle, and Louvet, and hid in a grotto at St Emilion. At length they were tracked and obliged to fly. The bodies of Pétion and Bazot were found in a cornfield, partly devoured by wolves. They were supposed to have died by their own hands.

**Petition**, a supplication preferred to one capable of granting it. The right of the British subject to petition the sovereign or either House of Parliament for the redress of grievances is a fundamental principle of the British constitution, and has been derived from very early times. The earliest petitions were generally for the redress of private wrongs, and the mode of trying them was judicial rather than legislative. The earlier petitions were generally addressed to the House of Commons first became frequent in the reign of Henry IV. Since the Revolution of 1688 the practice has been gradually introduced of petitioning parliament, not so much for the redress of specific grievances, as regarding general questions of public policy. Petitions must be in proper form and respectful in language; and there are cases where petitions to the House of Commons will only be received if recommended by the crown, as where an advance of public money, the relinquishment of debts due to the crown, or compensation for losses out of the public funds is prayed for. A petition must, in ordinary cases, be presented by a member of the House to which it is addressed. The system is, however, not without its disadvantages, as when the attempt is made to over ride the courts of law popular petitioning is a vast system being presented on behalf of murderers convicted after fair trial. For election petitions, see *Parliament*, Vol. VII. p. 775. The monster Chartist petition of 1848 claimed to bear six million signatures. In the 200 years ended 1848, petitions presented to the House of Commons were 70,072; in the five years ending 1872, 101,573;
PETITION OF RIGHT

PETRARCH

in the years 1873-81, 123,870. In one year (1875) there were as many as 20,610, signed by 3,088,970 persons. On the other hand, the year 1889 produced only 8317 petitions.

In the United States the right of the people to petition government is expressly secured by the First Amendment of the Constitution, and is thoroughly interwoven with the ideas and usages of the nation—although, indeed, conflicts with slavery, it was resolved that petitions relating to slavery or the abolition thereof should be laid on the table without being printed or read, and finally that such petitions should not be received at all.

Petition of Right, a declaration of certain rights and privileges of the subject obtained from King Charles I. in his third parliament—the first statutory restriction of the powers of the crown since the accession of the Tudor dynasty. It was so called because the Commons stated their grievances in the form of a petition, referring to accord the supplies till its prayer was granted. The petition professes to be mere expression and explanation of the ancient constitution of the kingdom; and after reciting various statutes that recognise the rights contended for, prays that no man be compelled to make or yield any gift, loan, benevolence, tax, or such like charge, without common consent by act of parliament; that he be called upon to make answer for refusal so to do; that freemen be imprisoned or detained only by the law of the land, or by due process of law, and not by the king's special command, without any charge; that persons be not compelled to receive soldiers and mariners into their houses against the laws and customs of the realm; that commissions for proceeding by martial law be revoked. The king at first eluded the petition, expressing in general terms his wish that right should be done according to the laws, and that his subjects should have no reason to complain of wrongs or oppressions; but at length, on both Houses of Parliament insisting on a fuller answer, he gave an unqualified assent on the 26th of June 1628. The text of the Petition will be found most conveniently in Gardiner's Constitutions Documents of the Puritan Revolution, 1623-80 (1889). See also his History of England, vi. 274-306.

Petitio Principii ("a begging of the principle or question") is the name given in Logic to that species of vicious reasoning in which the proposition to be proved is itself assumed in the premises of the syllogism.

Pétöfi, Sándor, Hungarian poet, was born on 1st January 1823 the son of a butcher, at Kis-Körös, in the county of Pest, and after school-days was successively actor, soldier, and literary hack. His first poem, published in 1842, was followed by a volume in 1843 which secured his fame as a poet. He diligently studied German, French, and English, translated Shakespeare's Coriolanus, but in 1848 threw himself heartily into the revolutionary cause, writing numerous popular war-songs. He fell in the battle at Scherbob (Segesvár), 31st July 1849; but it was long believed by the Hungarians that he had escaped, and would reappear. His lyrical poetry breaks completely with the old pedantic style till then in vogue, and, warm with human and national feeling, began a new epoch in Hungarian literature. The first collected edition of his poems appeared in 1874; since then they have been translated into English by Bowring and others. There are lives by Oját (1868) and Fischer (1888).

Petra (the Greek equivalent of the Heb. Sela, both names signifying 'Rock'), anciently the stronghold and treasure-city of the Nababatrakians (q.v.), was situated in the 'desert of Edom' in northern Arabia, near the points of intersection of great caravan-routes from Palmyra, Gaza, Egypt, and the Persian Gulf, four days' journey from the Mediterranean and five from the Red Sea. It was approached by a chasm or ravine, which in some places is only 12 feet wide, while the rocky walls of red sandstone tower more than 100 feet above. Along this ravine are the most famous ruin of Petra, the Khnsa or 'treasury of Pharaoh,' and a theatre, both shaped out of the solid walls. All along the face of the rocks that overlook the valley are rows of cave-dwellings hewn out of the solid stone, and ornamented with façades. The floor of the valley, about two miles across, is strown with ruins. The earliest name was probably Beken; hence Petra has been identified with Kadesh Barnea, and as the place where Moses struck the rock so that water flowed out. The little stream that descends the ravine, flowing eastwards, lends its origin in a spring called at the present day the Fountain of Moses. Petra was captured by the Romans in A.D. 106, and thereafter decayed, its place as a commercial centre being taken by Palmyra (q.v.). Nevertheless it continued to exist as a town; most of the ruined edifices belong probably to the first century of its decay. It is from Petra and not from the Greek word petra, that Arabic Petra gets its name. See De Luynes, Voyage d' Exploration (1803-50); Palombi and Domant, Arabie Pétrée (1850-54); Palmer, Desert of the Edos (1871); Stanley, Sinai and Palestine (1860); and other works cited at Edom.

Petrarch. Francesco Petrarca, one of the earliest and greatest of modern lyric poets, was the son of a Florentine notary, Pietro di Messer Parenzo, the name of Francesco Petrarca by which the poet is known being the Latinised form of Francesco di Petrarca, viz. Francis of Peter. Petrarca's father was exiled from Florence (1302) along with Dante during the struggles between the two factions of the Brunelleschi and Neri, when the latter party obtained the upper-hand. He took refuge with his family in Arezzo, where, on the 20th July 1304, Francesco was born.
The poet's infancy was passed in Tuscany until 1312, when his father determined to go to Avignon, which was then a papal court; but lately it was

ferred. There and in the neighbouring small town of Carpentras Petrarch's studies began, and were continued later at Montpellier and Bologna.

His father intended him to enter the legal profession; but instead of jurisprudence he devoted himself to that which his most intimate friends, his favourite authors, on whose style he afterwards strove to model his own, being Cicero and Virgil. It was only later in life that he tried to learn Greek, in which he never attained to any proficiency. After his father's death, whom his mother did not live to see again, Petrarch was left an orphan. As was the custom of the time, more especially at the papal court, he and that brother Gherardo, being without means, became ecclesiastics; but Francesco never took holy orders. His chief source of income became the small benefices ferred on him by his many powerful patrons; but in after-life he refused higher preferment, declining even the much coveted post of papal secretary, rather than compromise his independence. Petrarch is reported to have been a handsome young man of excellent family, and retained all the refinements of court-life. It was at this period of his life that he first saw Laura, the lady whose name he was to immortalise in his lyrics, and who inspired him with a passion which has become proverbial for its constancy and purity. The meeting took place in the April of 1327, and Petrarch's first sonnet to Laura was published in the Biblioteca of St. Clara at Avignon. This date, as well as that of Laura's death on the same day in the year 1348, stands recorded by Petrarch's own hand on the dy-leaf of his Virgil, now amongst the treasures of the Ambrosian Library at Milan. The identity of Laura is still the subject of much speculation; but one most generally accepted hypothesis is that of the Abbé de Sade, who identified the poet's love, on somewhat slender evidence, with a member of his own family, Laura de Noves, married in 1325 to a Hugo de Sade to become the mother of eleven children, and died in April 1348. It was also at this time that Petrarch's friendship began with the powerful Roman family of the Colonnas, and especially with Jacopo Colonna, Bishop of Lombez.

The dawn of the new birth of letters and art which was then beginning, was already altering the status of the poet and artist, and as the fame of Petrarch's learning and genius grew his position became one of unprecedented consideration. His presence at their courts was competed for by the most powerful sovereigns of the day, and such was the exceptional position he enjoyed that he has said of himself that princes had lived with him, not he with princes. His chief patrons were Pope Clement VI, the Emperor Charles IV, King Robert of Naples, the Viscount of Milan, Jacopo da Carrara, Lord of Padua, Azzo da Correggio, Lord of Parma; in Venice the senate bestowed a palace on him in return for his promise to leave that town his library; Florence offered him the restoration of the confiscated possessions of his family if he would reside there; and in Aragon a woman who was born was kept as a

durary. When wearied by court-life he sought retirement and quiet in his country-house at Vaucluse, near Avignon. He travelled repeatedly in France, Germany, and Flanders, wherever he went, searching diligently for manuscripts and enriching his collection. He made some valuable bibliographical discoveries, finding in Liége two new orations of Cicero, in Verona a collection of letters of the same writer, and in Florence a then unknown Institution of Quintilian's. In the cosmopolitan society of the papal court Petrarch became acquainted with learned men of all countries, whom he interested in his unwearied search for valuable manuscripts. The example given by Petrarch in his love of learning probably gave the first incentive to the collection of manuscripts which bore such rich fruits in the following century. But the most glorious moment of Petrarch's honoured career was when, invited by the senate of Rome on Easter Sunday, 1341, he ascended the steps of St. Peter's, to receive the crown, from his admiral, Robert of Anjou, King of Naples, and there, after delivering an oration on poetry and the significance of the laurel, he was crowned poet-laureate amid the acclamations of thousands. After this pagan ceremony he went to leave his crown on the tomb of St. Peter's. The news of the death of his beloved Laura and his friend Cardinal Colonna, he left Avignon for ever, disgusted with the corruption and vice of the papal court. The remaining years of his brilliant life were passed in various towns of Northern Italy, and in the retirement of a country-house at Arpach, near Padua, the only one of his many habitations still in existence. There, tenderly cared for by his natural daughter, Francesca, and her husband, and occupied to the last in his favourite studies, he quietly ended his life.

Petrarch may be considered as the earliest of the great humanists of the Renaissance and the founder of modern classic culture. His passionate admiration for antiquity and the classic authors was no longer that of Dante and the earlier writers, whose enthusiasm was incorporated with the feelings and needs of their own time and stamped with their own individuality. The more contemplative and less original mind of Petrarch lent itself rather to an entire withdrawal from and disdain for all that later times have produced, and his constant efforts to imitate are closely associated with the kind of thought and expression of the great Latin writers. He attained to a surprising purity of style in his Latin works, and the admiration which these writings excited in his contemporaries was boundless. Petrarch himself chiefly founded his claim to posthumous fame on his epic poem Africa, the hero of which is Scipio Africanus, and his historical work in prose, De Viris Illustribus, a series of biographies of classical celebrities. His other important Latin works are the elegies and epistles in verse; and in prose the dialogues, De Contemptu Mundi and Secrecum, and the treatises De Oti Religiosorum (written while visiting his brother, who had joined a Carthusian brotherhood) and De Vita Solitaria (written at Vaneluse); and particularly important for historical and biographical purposes is the numerous collection of letters divided into Familiaria, Variae, Ad Veteres Illustres, Seniles, and Sine Titulo.

Petrarch was an ardent patriot, but he had little practical influence on the political life of his time. His理想 were those of a poet, and not of a

stateman. However great his merits as patriot or student, his name would be little remembered now; it is by his lyrics alone that his fame has lasted for over five centuries. His title-deeds to fame are in his Causicentri, in the sonnets, madrigals, and songs written in Italian, almost all inspired by his unwieldy passion for Laura, and in which the character of the man and the reality of a strong sentiment find their expression. The history of Petrarch's love presents few incidents; its entire interest lies in the intense and unadorned passion which we see the picture of a human soul in all its contradictions, pains, and struggles. Such self-analysis was unknown in medieval writers, and Petrarch has therefore been called the first modern man. His later life was one of rest and tranquility, 'I Triomphi' ('Triumphs'), also in Italian, and is of unequal merit, the only remarkable
passages being those which refer to the beginning of the poet's love ('Triumph of Love') and to Laura's death ('Triumph of Death'). Few of Petrarch's lyrics treat of other subjects, but amongst these few are three of his finest efectone, which address to his country ('Italiam'), in which he reproaches the Italian princes for their dissensions, and for calling to their aid the mercenary 'barbarisms' who were the scourge of Italy, words repeated by Machiavelli in his Prince, a century and a half later, and in our own day in the struggle for freedom from Austria; the second (Spero Gentii), which some commentators consider to be addressed to the young Coloma, and others to the famous Cola di Rienzi, whose wild attempt to resuscitate the ancient forms of republican government in Rome had fired Petrarch with enthusiasm; and the third (O Aspettando Ciel Bento e Bella Animala), addressed to his friend Jacopo Colonna, to incite him to join the crusade of Philip of France against the infidels. Petrarch was in constant correspondence with his great contemporary, Giovanni Boccaccio (Lettere di Boccaccio, ed. by Corazzini, Florence, 1877), and translated into Latin his friend's tale of Patient Griselda (De Odiositatis ac Fide Uxorii). Chancer alludes to this when he says of his Clerk's Tale:

Lear'd at Padova of a worthy clerk,  
Francesco Petrarch, the fairest poet,  
Hight this clerk, whose rhetoric wrote  
Enamour'd at Illeito of poetry.

The earliest complete edition of Petrarch's works is Franzensi Petrarchae Opera Omnia (Basel, 1534, fol.), and have since gone through innumerable editions, with or without commentary. The most reliable is that of Mansand (Padua, 1819, 4to); his text is used by Leopardi, in the Italian edition of the poetry (Milan, 1839), often reprinted. The letters have been edited by Fracassetti, and partly translated into Italian, with a valuable commentary (Florence, 1839-63-69). See the Abbe de Sade, Memoires de Petarque (1764); Mozziere, Petarque (1863); Koerting, Petrarques Leben und Werke (1878); the little monograph by Henry Reeve (1857); also Gaspary, Italianische Literatur (Berlin, 1885); Bartoli, Letteratura Italiana (Florence, 1854); De Santis, Storia sul Petrarco (Naples, 1869); Zambini, Studii sul Petrarca (Naples, 1878); Voigt, Wiederbelebung des geschlossenen Alterthums (Berlin; 2d ed. 1890); and Symonds, Renaissance in Italy (2d ed. 1886).

Petræ, an English Catholic family, descended from Sir William Petre, secretary of state in the reigns of Henry VIII, Edward, Mary, and Elizabeth. The most notable member was Edward Petre the Jesuit (1631-99), who shared the captivity of his kinsman Lord Petre in the Tower in connection with Oxen's 'Papist Plot,' but released by James II. sat in the Privy-council. He was abhorred as James's evil genius, and escaping at the Revolution became rector of St. Omer.

Petræi (Procollararia), a genus of sea-birds of the family Procellaridae, which includes the albatrosses, shearwaters, fulmars, and petrels proper, and is allied to the gulls and petrels. The true petrels, of which there are eighteen widely distributed species, are long-winged birds of powerful flight; the bill is broad and of medium length; the hind toe is very small; the claws are narrow and pointed; the incubant is long and slender, and the tube-like nostrils are set close beneath them. They are strictly oceanic, and visit coasts and islands only for breeding purposes. The best-known species is the Stormy Petrel (P. pelagica) or Mother Carey's Chick, which is scarcely larger than a lark, and is the smallest web-footed bird in the world. The head and back are sooty-black, the wings black, with streaks of white, the under surface greyish black, the bill black, and the feet reddish brown. The name Petre—a diminutive of Peter—refers to its apparent walking on the water, the lightness of its body enabling it to skim up and down the waves, even in a storm, with only enough motion of the wings to keep the feet from sinking under the surface. Because of its frequent occurrence before or during stormy weather, the molluscs and other animals upon which it feeds are driven to the surface, and possibly also because of its blackness, it is regarded by sailors as a bird of evil omen.
PETROGRAPHY

importantly, the pyramids and temples of Egypt (book, 1887), and equally well by its being rendered as a composite of the mound. Fund, to the mounds of said—the Scripture Zoro, the forgotten city of Nankratis, Anu, and Defenndl. His Memoirs on Tanis (1885–90), on Naukratis (1886), on Tel el Hesy, the site of Lachis (1891), on Medmen (1882), and on Ten Year's Diggings (1892), are generally regarded as an important contribution to the science of the ancient world.

Petritiation, a name given to organic remains found in the strata of the earth, because they are generally more or less mineralised or made into stone. The word has fallen very much into disuse, having given place to the terms Fossil (q.v.) and Organic Remains. The name petritiation is also loosely used of an object which, from being exposed to the action of limy or other water, becomes covered with a crystalline deposit. See (under Fossil) Fossil Forests.

Petro-Alexandrovsk, the seat of administration of the Amu-Daria district, is little more than a fort, and is situated on the Lower AmuDaria or Oxus (q.v.), 30 miles E. of Khiva.

Petrography is that branch of geological science which deals with the minerals and rocks of the earth, from the point of view of their origin, and hence by many geologists the term Petrology is preferred as a name for this branch of science. Others use Petrography in a similar sense. For a general account of rocks, their mineral composition, and their relations to geological processes, see the section Petrology under GEOLOGY.

Petrographers are hardly yet agreed on any particular classification of rocks, not certainly from the want of materials, for a very large number of so-called rock-species have been described, but in the case of the crystalline igneous rocks so many gradations exist between one kind and another that the definition of rock-species is often very difficult. As careful descriptions and comparisons are not yet universally submitted to a classification, it may be necessary to form several intermediate groups of the igneous rocks which flourish at present; species will come to be included as mere varieties of a few well-marked types.

In examining a rock the petrographer notes first the crystallography, which can be seen by the naked eye (nacreous or epitactic), such as its structure (whether crystalline, vitreous, compact, or chalybite, &c.); its state of aggregation or relative hardness; its colour; its composition; and specific gravity—which may vary from 0.6 among the hydro-carbon compounds to 5.1 among the basalts, the average specific gravity of rocks in general being about 2.5 or a little more. In the case of many coarse-grained rocks, especially those belonging to the derivative division, it is hardly requisite to go beyond a macroscopic examination. But when the rock consists of small grains, it is subject to closer scrutiny. Thin slices are therefore prepared for microscopic study, after which it is frequently found that the apparently smooth compact mass turns out to be composed wholly or largely either of crystalline or of fragmental materials. Even in the case of rocks which are manifestly crystalline, and the mineral ingredients of which can be determined macroscopically, it is necessary that a microscopic examination should be made. When this is done the rock will sometimes be shown to contain minute crystalline

granules and crystals, or small quantities of non-differentiated matter and glass which quite escape the unassisted eye. The minute structure of the various rocks, especially of the igneous rocks, is determined by means of the microscope, and the chemical changes which they may have undergone since the time of their formation are carefully studied. In this way much light has been thrown on the genesis of rocks and the changes which these have subsequently undergone.

Of the minerals known to science comparatively few are rock-formers; the larger number of these are practically confined to the igneous and sedimentary rocks, very few entering into the formation of the more important rocks of the Earth. The chemical constituents of the igneous rocks are grouped as essential, accessory, or adventitious, and secondary. The essential minerals are the most important, as it is upon their presence that the various species of rocks depend. Accessory minerals are accidental ingredients, the presence of which does not affect the specific character of a rock; if sufficiently prominent or remarkable they merely give rise to varieties. Secondary minerals are the products of chemical changes subsequent to the formation of the rock in which they occur—the secondary mineral species are accumulated upon the primary mineral species of the rock. Some of the secondary essential minerals of igneous rocks are quartz, felspar, nepheline, leucite, pyroxene, hornblende, mica, and olivine. All these also occur as accessory ingredients, and there are many other accessory and mineral species which may be named—magnetite, ilmenite (see IRON), apatite, schoorl, titanite (sphele), haliyne (nosean), zircon, &c. Amongst the secondary minerals and decompositions in igneous rocks are quartz, chlorite, hornblende, biotite (see IRON), zoisite, epidote, chlorite, serpentine, green-tourmaline, &c. The chief mineral constituents of the Schisto rocks are the following: Quartz, mica, felspar, talc, chlorite, hornblende, actinolite (see AMPHIBOLE), omphacite, seragolite. Less prominent ingredients are muscovite and chloritised, which are called othrite, kyante, magnetite, schoorl, scholle, epidote, pyrite, specular iron, &c. The derivative rocks having been formed out of the debris of pre-existing rock-masses, whether igneous, schistose, or sedimentary, it is obvious that they may contain many of the minerals already described. There are many cases where they are composed of gneiss, the ore of granite or gneiss. But most of the minerals which aqueous rocks have derived from crystalline igneous and schistose rocks are more or less altered—to the felspars are kaolinised, the micas are reduced to non-calcic scales or folia of a dull grey colour and much diminished lustre, the pyroxenes, amphiboles, olivine, &c. are either unrecognisable or represented by decomposition products. Quartz, as might have been anticipated, owing to its resistance to the chemical action of water and its superior hardness, is the common mineral constituent of derivative rocks. The clay-rocks consist in large measure of the insoluble residue of the various silicates of alumina and the alkalies and alkaline earths, of which the alums and silicates are generally largely composed. The readily soluble and readily precipitated minerals calcite, dolomite, rock-salt, and gypsum are also important rock-formers in certain groups of derivative rocks. As binding materials (i.e. the mineral cements which hold the grains of many sedimentary rocks together) we have quartz, chalcedony, opal, &c., calcite, haematite, and limonite (see IRON), dolomite, siderite, &c. The rocks which are mainly composed of organic debris necessarily consist chiefly of calcareous and carbonaceous materials.
For purposes of description rocks may be grouped in the three following divisions: (1.) Igneous Rocks; (2.) Derivative Rocks; and (3.) Schistose Rocks.

1. Igneous Rocks (q.v.).—Of these there are two series—(a) crystalline and (b) fragmental or clastic. The crystalline series includes semi-crystalline and vitreous rocks, which are some of the more important varieties of which may be noted. These vitreous rocks usually contain crystals and microlites, and they often show perlitic and spherulitic structures. Some varieties are highly porous and frothy (spongolites, pumicite). Others are comparatively homogeneous, closely compact, and smooth like bottle-glass; while yet others are markedly porphyritic, usually with crystals of sandstone (see Felspar). Such vitreous rocks are most usually acidic (i.e. highly siliceous), but basic glasses are also known. The semi-crystalline rocks are composed of crystalline minerals and glassy matter in varying proportions. The crystalline ingredients often show minute inclusions of other minerals (endomorphs) or of glass, &c., which have been caught up while the vitreous rock was still in a semi-fluid state. Frequently also the crystals contain minute cavities which may be empty or filled with some liquid or gas. The whole crystalline rocks contain of course no glass or non-differentiated matter. It is in this class of rocks—many of which are of pheno-lithic, the semi-crystalline rocks—of which most recent occurrence in the constituent minerals. In the minerals of semi-crystalline and crystalline rocks which have been erupted at or near the surface liquid cavities are less common. In vitreous, semi-crystalline, and crystalline rocks alike the mineral ingredients are not solidly disposed in lines or bands. This is called fusion or fluidal structure—the ingredients having arranged themselves in this manner while the igneous rock was still and in motion. Although not unknown in some holocrystalline rocks, it is a structure which is more characteristic of the vitreous and semi-crystalline rocks which have been poured out at the earth's surface as lavas. The appearance of the original mineral constituents of many igneous rocks shows that their crystallisation cannot have taken place contemporaneously in most cases, but rather that they belong to two stages in the consolidation of the rock which they form a part. Thus, in many crystalline and semi-crystalline rocks we readily distinguish a crystalline or semi-crystalline ground-mass, scattered through which occur larger crystals, many of which may be broken and corroded. These latter are believed to have crystallised while the molten rock was still at a considerable depth below the surface. Afterwards, when the fluid mass was poured out at or near the surface, and cooled rapidly, the smaller minerals and glassy matter of the ground-mass were formed. Although these two classes of minerals can be seen most clearly in rocks of a trachyctic and porphyritic aspect, yet even in granitoid rocks evidence of two stages or periods of consolidation can often be detected. The general character of fragmental igneous rocks is described in the article On the Petrolerous Limestone, Teff, and Igneous Rocks. Most of the rocks mentioned in the following tables have separate articles assigned to them.

(a) Petrology and Crystalline Series:

1. Orthoclase Rocks: obsidian, pumice, phonolite, trachyte, rhyolite, obsidiophrye, quartz, trachyte, phonolite, syenite, &c.
2. Plagioclase Rocks: andesite and porphyritic, diorite, basalt, gabbro.
4. Diabase Rocks or Pérorites: picrite, biotrite, diorite, &c.
5. Astmat Ixogous Rocks: various serpentines rocks.

(b) Fragmental or Clastic Series:

(b) Volcanic agglomerate, volcanic breccia, tuff: volcanic sand, ashes, dust, blocks, lapilli, and bombs.

11. Derivative Rocks.—As water has played a very prominent part in the formation of this great division of rocks, these are frequently termed aqueous or sedimentary. Such being the origin of by far the greater number of rocks in the sea, or beds, hence the name by which they are also widely known—stratified rocks. Some of the members of this division, however, are not of aqueous origin, while others do not occur in beds. But they are all alike in so far as the water has something to do with which they are derived by epigene agents from the degradation of pre-existing rocks, minerals, and organic bodies.

1. Gravel and Sand Rocks: rock-debris and breccia; rain-wash and brick-earth; soil and subsoil; sand and gravel, conglomerate; sand, sandstone, and grit; greywacke.
2. Clay Rocks: kaolin, piper-clay, illite, brick-clay, fuller's earth, bentonite or ill-tile, bentonite, argillaceous shale.
3. Calcareous Rocks: limestone and its many varieties (such as calcilean, chalk, oolite, marl, com-frock, &c.), dolomite, &c., in such manner as limestones.
4. Ironstone Rocks: limonite, hematite, spolite iron ore (spheroidal, blackband hematite), manganese iron ore.
5. Siliceous Rocks: siliceous coquina, chert, limestone, pyritic stone, jasper, &c., triplite and radiolarian oxe.

111. Schistose Rocks.—The more representative rocks of this division are more or less crystalline and schistose or foliated (see Foliation). Some, however, show faint traces either of crystalline or foliated structure; while others, although distinctly crystalline, are not schistose. Again, some of the rocks are fragmental, with more or less of superinduced crystalline structure. Many schistose rocks are clearly of metamorphic origin. They are altered igneous and derivative rocks. The origin of others is still obscure. See Archæological System, Geology.

Quartz-rock, quartz-schist baioliths, schistose conglomerate, clay-shirt and its varieties, phyllite, mica-schist, talc-schist, chlorite-schist, amphibolite-schist (actinolite-schist, hornblende-schist), gneiss, granite, schist, paragonite rock, marble.

See Rutley, The Study of Rocks (1879); Hatch, Petrology (1881); Cole, Aids in Practical Geology (1891); Einführung in die Mechanik der Erde (1879); Kalckowsky, Elemente der Lithologie (1861); Jannettaz, Les Roches (1884). More advanced works are Teall, British Petrography (1888); Fouqué and Lévy, Mineralogie de la France (1879); Rosenbach, Monographie physiographique des Minerals et leur texture (1885); Zirkel, Mineralogie der Braunkohlen der Mineralie. und Gesteine (1873).

Petroleum (from Lat. petra, a rock, and oleum, oil), rock-oil, an inflammable, dark liquid, essentially composed of carbon and hydrogen, which exudes from the earth in various parts of the world.

(1) General History.—It is impossible to state when petroleum was first discovered. In some form it seems to have been applied to the uses of mankind in the earliest periods known to history. The ruins of Nineveh and Babylon indicate that the asphaltic mortar used for their walls and buildings was made from a partially evaporated petroleum, obtained, doubtless, from the springs of Is, on the Euphrates. This is amply confirmed by the passages of Scripture (Gen. xi. 3). Horseldus (l. 119; iv. 195), 500 B.C., writes of the springs in the island of Zante, 'I have myself seen pitch drawn out of a lake and from water in Zacynthus.' &c. Strabo (xvi. 2) refers to the bitumen found in the valley of Judah, and sold to the Egyptians for embalming.
Diodore describes the same product obtained from a lake in Sicily and sold for the same uses. Pliny, in his histories, realizes the famous mention of the deposit in Albana on the Adriatic Sea. The holy fires of Bakou on the Caspian Sea, worshipped for ages by the people dwelling near, and the goal of pilgrimages even from India (see Vignes’ Travels in Caucasian and Little Tibet), have been supported by apparently super-abundant petroleum stores. The North American Indians collected what was known as Seneca Oil from petroleum springs, and the indications are that long before them the Mound Builders, who worked the copper-mines of Lake Superior, the lead-mines of Kentucky, and the mica-mines of North Carolina, not only gathered the oil coming from natural springs that appeared on streams, but even dug numerous wells in Pennsylvania, Ohio, and Canada, and dipped up the oil that flowed into them. Trees now growing in the earth thrown out in digging the wells, actually wells themselves, show that the work was done from 500 to 1000 years ago.

(2) Growth of the American Industry.—But the growth of the American industry, which has given the old world a new and fairer term to the people’s light, has been within the last 20 years of the century. From 1850 to 1858 many experiments were made with petroleum, both in the line of collecting the crude article and of refining it when secured, but with indifferent success. Among the promoters of the effort was the Pennsylvania Rock Oil Company, incorporated in 1854 under the laws of the state of New York. The superintendent of this company, E. L. Drake, in 1858 started to sink a well in one of the old pits supposed to be of prehistoric origin, near Titusville on Oil Creek, Venango county, Pennsylvania, and the Alleghany River. Adventurers and investors flocked thither from all parts of the country. What was known as the oil region was transformed from an almost unbroken forest into camps and towns in which fortunes were made in a day, and often as quickly squandered. Many wells yielded nothing, others lasted but a short time, while some gave enormous quantities of oil. But the producing fields were few, and are, still constantly changing; new ones being discovered, old ones failing. For example, Pittsboro City, near Titusville, Pennsylvania, in 1865 next to Philadelphia the largest post-office in Pennsylvania, has now entirely disappeared, and the site of the city, become a farm. Crude petroleum is at present secured in many parts of the state of Pennsylvania. Special mention might be made of M’Kean, Warren, Elk, Forest, Erie, Crawford, Venango, Clarion, Butler, Washington, and Greene counties. It is also produced in some parts of North Carolina, Ohio, Western Virginia, Colorado, Wyoming, Kentucky, California, and Texas, and in 1897 an important petroleum lake was reported to have been discovered in Alaska.

Between 1860 and 1867 the product of petroleum in the United States increased from 3, 343,000 barrels in production in 1867 being 69, 505,801 barrels, of a value of $40,929,011, while the export of mineral oils had a value of over $56,125,000. In the same year the United Kingdom imported 185,665,376 gallons, valued at £3,335,271. The use of petroleum for fuel, as in motor-cars (see GAS-ENGINE) has of late greatly extended.

The accompanying table gives the production of crude oil in the United States, the stocks, and the value of the wells for each year, 1861 to 1899 inclusive. The unit of measurement of crude oil is a barrel of 42 gallons.

There are no reliable statistics showing the number of producing wells in existence. It is estimated by those best informed on the subject that in what is known as the Pennsylvania fields there were in 1891 between 30,000 and 40,000. At first the wells were all flowing wells, extending down to what was termed the first sand. Afterwards wells were sunk to the second and third sands. The average depth is from 1800 to 1800 feet, the shallowest wells being about 500 feet, the deepest about 3600 feet. Many wells, particularly when first completed, are flowing wells; that is, the oil is forced up through the tube composing the well, and reaches the surface of the ground without pumping. This of course indicates that the oil in the reservoir below the surface of the ground is held under pressure; but as an outlet is given for the oil the pressure subsides, and then becomes necessary to lift the oil by pumps. There are to-day a few flowing wells in America, but practically all the wells are pumped. Crude petroleum as it comes from the ground varies in general appearance from a bright lemon colour to a greenish black, all the interchanging shades being found, and in gravity (weight or density) from 38 of Baumé’s scale to 50, all the intermediate gravities being secured. The same well will, at different stages of its life, give oil of different colours and gravities, the colour growing darker and the gravity heavier as the well grows older. In 1802 it was found that in many cases dry wells could be made to resume their yield, and declining wells to continue production by being shocked with torpedoes. In 1897-98 a commission took evidence in England as to whether petroleum with a flash-point less than 72° (Abita close test) is dangerous, and reported by a majority that a flash-point at 100° should be taken as the standard of safety. And see EXPLOSIVES.

One of the most interesting features of the growth of the petroleum industry is found in the devices for transportation. The oil was at first carted in barrels over rough roads to the point of consumption or of loading into railroad cars. The wooden barrel gave place to light iron tanks on wheels, and the ordinary freight car for oil in barrels to wooden tank-cars, and these in turn to
iron tank-cars, some of which are of 3000 gallons capacity. But the greatest advance was made when pipe lines for the transportation of petroleum were introduced. Samuel Van Syckle, of Titusville, Pennsylvania, put down the first successful line, extending from Titusville to Claysville, a distance of about 35 miles. The oil region is now a network of pipes. They carry oil from the wells to central points for storage or for delivery to the trunk lines to be pumped to the refineries. Powerful pumps move the oil rapidly in vast quantities for great distances. This is done to fifteen or twenty thousand lines of 6- and 8-inch pipe, carrying the oil from the point of production to the refineries handling it. The most important lines are known as the National Transit Line, South-west Lines, Maucksburg Line, Tilewater Line, Western and Atlantic Line. By these crude oil is delivered at New York, Philadelphia, Baltimore, Cleveland, Buffalo, and Chicago. The total length of these main lines and their several branches and feeders is fully 25,000 miles. The American trade in petroleum is largely controlled by the Standard Oil Company.

(4) Petroleum in Other Countries than the United States. There are oil fields in many countries other than those in the United States. Producing petroleum in commercial quantities—those of Baku, Burma, Canada, Galicia, Peru, Japan, and, last to be developed, of Langkat, or Lankih, in Sumatra.

The Baku (q.v.) field yields immense quantities of crude of low gravity, which on being distilled gives only a small percentage (25 to 32) of burning oil of satisfactory quality. However, as the crude is very cheap, and the balance of the product from distillation can be sold for fuel, the refiners of the Russian crude have been able to compete with other refiners for a share of the world trade in petroleum. The petroleum of Canada, like that of several fields in the United States, particularly in the state of Ohio, is of low gravity, 26 to 42 Baumé, and has a peculiar smell and nauseous smell, on account of the sulphur it contains. It has been difficult to secure a market, but production has been fostered, and it supplies a large demand throughout the British provinces. The Japanese field has been known for many centuries, but the cheapness of the American refined products renders it unprofitable for products from the Japanese to compete. Production has been completely checked.

(5) Origin of Petroleum.—This topic is treated here somewhat out of its natural order, not because it is lacking in interest, but because so little seems to be known about the chemical geology of petroleum. There have been three leading theories advanced, under some one of which all of the results from different lines of investigation can be classified: (1) Petroleum is a distillate produced by natural causes; (2) petroleum is indigenous to the rocks in which it is found; (3) petroleum is a product of bacterial action. A full summary of the results of the investigations under each one of these theories is given by Professor S. F. Peckham in his report as special agent of the United States census for 1880. He inclines to the belief that Pennsylvania petroleum is of vegetable origin and the result of bacterial action.

Norman Tate, Petroleum and its Produce (1863), and Examination of Petroleum, &c. (1869); Draper and Pease, History of Petroleum,
PETROUSE

**PETROUSE**, a name given to the women of the French Company of 1871, who helped to burn the Tulleries, Hôtel de-Ville, and other public buildings by pouring petroleum on them.

**Petronez'on.** See LAMPREY.

**Petronei,** an ancient and clumsy description of pistol.

**Petrourius,** surnamed 'ARRIRER,' from his supposed identity with the Cains Petronius whom Tacitus calls 'wiser elegantissimum' at the court of Nero, is generally believed to be the author of the satirical romance or collection of satires of which the 15th and 16th books have, though in a fragmentary state, come down to us. The work seems to have been a novelty in Latin literature, consisting of a series of mock depictions of the licentious life in Southern Italy of the upper classes. Its artistic merit is great, in strength of portrayal and colour anticipating Zola, with a vein of humour as original as it is refined. Bücheler, its latest and best editor (Berlin, 1882), and Cesareo, its ablest critic (Florence, 1887), both support the long-prevailing view that its author was no other than the Petronius above referred to—a pro-consul of Bithynia and afterwards consul, a lusty master in all the arts of the voluptuary, the aider and abettor of Nero and the jeunesse dorée of the 1st century in every form of sensual indulgence. The favour he enjoyed at court aroused the jealousy of another contaminant of the emperor's, Tigellinus, who, though good enough to guide his disgrace and punishment. He had proceeded to carry on the work of research in Caphania, precipitated his determination to destroy himself. True to the cynical side of his philosophy he set about his suicide in the most leisurely fashion, so as to glide out of existence 'without undue haste,' and opened his veins at intervals and then rebandaged them. Attended by a swarm of topics, and listening to songs and vers de société when not transacting business or taking a siesta. Shortly before expiring he drew up, signed, sealed, and sent to Nero a summary of the tyrant's amours and excesses, none of which is supposed to have been embodied in his satires. The work, fragmentary as it is, has drawn around it quite a library of criticism and controversy, of which Cesareo gives an excellent résumé, whilst promising a yet fuller treatment on the subject. In style it represents the high-water mark of silver-age Lutinity, while, as a picture of the 1st century on its seamiest side it shows better than any other how Christianity had become a necessity, if only to save the morality of the world.

**Petropavlovsk.** a town of Asiatic Russia, in the province of Awkistol, on the river Ishin, 175 miles WNW. of Omsk. Pop. 11,406. It is an important military station, with a fort founded in 1792, and has a large transit trade. Petropavlovsk is also the name of a small port on the east coast of Kamchadka (q.v.) with an admirale harbour.

**Petropavlovsk.** a town of Russia, 65 miles NW. of Saratov, on a tributary of the Don. Pop. 15,316.

**Petrozavodsk.** a town of Russia, on the western shore of Lake Onega, 300 miles NE. of St. Petersburg. It is a cannon-founding and small-arms factory, built in 1774 on the site of an iron works started by Peter the Great in 1763. Pop. 11,027.

**Petrus Alphonius.** See FABLE.

**Pettenkofer, MAX VON,** chemist, was born near Neuburg on the Danube, 3rd December 1818, studied at Munich, Würzburg, and Giessen, and in 1847 becomes professor of Chemistry at Munich. He has made valuable contributions to science on subjects as various as gold-refining, gas-making, ventilation, clothing, the influence of soils on health, epidemics, and hygiene generally. His *Handbuch der Hygiene* (1832 et seq.) is his best known work. He resigned in 1894.

**Pettic, JOHN,** painter, was born at Edinburgh, 17th March 1809, was brought up at East Linton, studied art at Edinburgh, and died at Hastings, 21st February 1893. 'The Prison Pet' was exhibited at Edinburgh in 1839, and 'The Armourers,' at the Royal Academy in 1860. But the first work which showed his characteristic qualities of strong imaginative grasp of his subject, and movement, and vigorous treatment was the 'Drunken Court-martial' (1864). Among the hundreds of later pictures, including portraits, may here only be named 'An Arrest for Witchcraft' (1866), 'Scene in the Temple Gardens' (1857), 'Juliet and Friar Laurence' (1874), 'The Death of a Warrant' (1879), 'The Vigil' (1884), and 'The Chieflain's Candlesticks' (1886). Pettie was elected A.R.A. in 1866, and R.A. in 1873.

**Petty,** SIR WILLIAM, a man of singular versatility, best known as a political economist, was born at Romsey in Hampshire on 26th May 1622, and educated partly at Caen, partly at the universities of the Netherlands, and at Paris. His versatility and talent are evidenced by the positions he successively held, and the subjects he interested himself in: he taught anatomy and chemistry at Oxford (1648), and was made professor of Anatomy there (1651); was professor of Music at Gresham College, London; was physician to the army in Ireland (1652), executed a fresh survey of the Irish lands forfeited in 1641, started ironworks, lead-burners, sea-fisheries, and other industries on estates he bought, in procuring the west Irish timber for Henry Cromwell when he was lord-lieutenant of that island; was made surveyor-general of Ireland by Charles II., who knighted him; invented a copying-machine (1647) and a double-bottomed sea-boat (1663); and in early life took much interest in education. In political economy he claims a place as one of the most important precursors of Adam Smith, on the strength of his Treatise on Taxes and Contributions (1662) and his Political Arithmetic (1661), the latter a discussion of the value of comparative statistics. He died in London on 16th December 1687.

**Pettie Bag Office,** one of the branches of the Court of Chancery, was abolished in 1874, and its duties were transferred.

**Pettty Officers** in the Navy hold a similar rank and position to the non-commissioned officers in the army. They are the backbone of the Navy, as the efficiency, smartness, and morale of a ship's company depend in no small measure upon the zeal and discretion of the petty officers. They are now a most highly trained and valuable body of men, and all the warrant officers are drawn from their ranks. They are divided into four classes—viz. chief petty officers, 1st- and 2d-class petty
officers, and leading seamen—and into two branches, the seamen and the so-called non-combatants, which latter includes the artificers, writers, &c. A chief petty officer can only be disrated with the sanction of the commander-in-chief, and in the case of a chief engine-room artificer his disrating must be specially reported to the Admiralty, and he can only be restored to his rank by Admiralty order. All other petty officers can be appointed or disrated by the captain of the ship, except in the case of gunnery or torpedo instructors, who are rated as such for their special qualifications in the gunnery and torpedo schools. The pay of the chief of police (master-at-arms) ranges from 4s. to 6s. a day; that of chief engine-room artificer from 6s. 6d. to 7s. 6d. a day, with an extra penny for each good-conduct badge; a chief gunner or torpedo instructor receives 4s. 2d. a day, with an additional penny for each badge, of which he can have three. A 1st-class petty officer, if a gunnery or torpedo instructor, obtains 3s. 8d. a day, with an extra penny for each badge; if not an instructor, but a trained gunner and torpedo man, 3s. a day; a 2d-class petty officer, if a trained gunner and torpedo man, 2s. 8d. a day, with pay for badges; while a leading seaman receives 2s. 6d. a day, with pay also for badges. A leading stoker receives 2s. 5½d. a day, and if a trained mechanic, 2s. 8d.; a carpenter's mate, 4s. 6d.; and a 1st-class writer, 5s. See WARRANT-OFFICERS.

**Petunia**, a genus of plants of the natural order Solanaceae, natives of the warmer parts of America. They are herbaceous plants, very nearly allied to Tobacco, and with a certain similarity to it in the general appearance of the foliage, which has also a slight viscosity, and emits when handled a disagreeable smell; but the flowers are very beautiful, and varieties improved by cultivation are amongst the favourite ornaments of British greenhouses and flower-borders. The petunias, although annuals or perennials, are very often treated as annuals, sown on a hotbed in spring, and planted out in summer, in which way they succeed very well even in Scotland. They are tall plants, with branching weak stems, and may readily be made to cover a trellis. Though treated as greenhouse plants, they become half-shrubby, they live only two or three years. The name is from the Brazilian *Petun*. The first petunia was introduced into Britain in 1831. There are now many garden varieties with double flowers, individually more durable than the single kinds.

**Petunze.** See Felosper, Pottery.

**Petworth.** A market-town of Sussex, on an eminence near the Weft Rother River, 14 miles NNE. of Chichester. Petworth House, the seat of Lord Leconfield, is an 18th-century mansion, with a fine park and many portraits and other relics of the Percies and Wyndhams. Pop. of parish, 2042. See P. H. Arnold's *Petworth* (1864).

**Pew**, (anciently puzs; Old Fr. prys; Dutch pusz; Lat. podium, 'anything on which to lean'—*appuyer*), enclosed seats in churches. Church-seats were in use in England some time before the Reformation, as is proved by numerous examples still extant, the carving on some of which is as early as the Decorated Period—i.e. before 1200 A.D.; and records as old as 1450 speak of such seats by the name of *puzs*. They were originally benches, usually facing east, with partitions of wainscoting about three feet high, and ends of the width of the seat, panelled or carved; these ends often rising above the wainscoting, and ending in flores-de-lis or 'poppy-heads,' as shown in the illustration.

**Pentinger, Conrad** (1465-1547), a scholarly citizen of Augsburg, and keeper of the archives. He published a series of Roman inscriptions; and at his death the so-called *Tabula Pentingeriaca* was in his possession, in course of being prepared for publication. This remarkable Itinerary (q.v.) is really a Roman map of the military roads of the 3d century A.D., though his copy was probably a 13th-century one. The document was sold by his family, bought by Prince Eugene in 1714, and is now in the Imperial Library at Vienna. It was edited and published by Schley (1733), Mannert (1824), and Desjardins (1869).

**Pews**. The benches here in Pressingfield Church, Harleston, Suffolk, and date from the later half of the 15th century. The back of the one in the engraving is quite a 'poor man's Bible,' being carved with the emblems of the Passion, from the cock crowing to the seamless coat. In later times, rows grew into to large and high seats containing two or more seats, lined with baize, and fitted with doors, desks, and cushions; but these will soon have all been swept away in England under the influence of the restoration movement and of the Free and Open Church Association founded in 1885 for the abolition of appropriated seats. Pews were early assigned to particular owners, but at first only to the patrons of churches. A canon made at Exeter, in 1287, rebukes quarrelling for a seat in church,
and decrees that none shall claim a seat as his own except noblemen and the patrons. Gradually, however, the system of appointment was extended to other inhabitants of the parish, to the injury of the poor, and the multiplication of disputes.

The law of pews in England is briefly this. All church seats are at the disposal of the bishop, and may be assigned by him, by faculty, to persons owning parsonage lands in the parish. Long occupation may give an owner of property a prescriptive title to a pew. Subject to rights acquired by faculty or prescription, the churchwardens are required to find seats for the parishioners, according to their degree; they may assign a pew to a parishioner, but not to a stranger. In England, pew-rents are recalled. In new churches pews may be assigned and pew-rents levied under several acts of parliament. See Dale's Clergyman's Handbook. It appears that by common law every parishioner has a right to a seat in the church, and the churchwardens are bound to place each one as best they can. The practice of letting pews, except under the church-building acts or special local acts of parliament, and, much more, of selling them, has been declared illegal.

In some parishes in the parish churches are assigned by the Heritors (q.v.) to the parishioners, who have accordingly the preferable claim on them; in towns the practice is to let them annually. As is well known, pews in dissenting churches are rented as a means of revenue to sustain general charges. In some parts of the United States pews in churches are a matter of annual competition, and bring large sums. Latterly, in England, there has been some discussion as to the injuriously exclusive character of the 'pew system,' and in many churches the open seats or chairs are unappropriated and distributed to all comers as a matter of ritualistic churches the sexes are divided, as in some country churches has been the case with the pews in churches where pre-Reformation days. In the Roman Catholic churches on the Continent pews are seldom to be seen.

Pewsey, a small market-town of Wiltshire, in a fertile vale, 18 miles E. of Devizes and 7 SSW. of Marlborough. Pop. of parish, 1853.

Pewter, a common and very useful alloy of the metals tin and lead. See Alloy.

Pézenas, a town of France (dept. Hérault), on the left bank of the river Hérault, 32 miles by rail SW. of Montpellier. The vicinity produces excellent wine, and woollen and linen goods are manufactured. Pézenas is one of the principal brandy-markets of Europe. Here Molière wrote Les Précieuses Ridicules. Pop. 6538.

Pfiffers, hot springs in the canton of St Gall, Switzerland, in the deep and gloomy gorge of the Tamina torrent, which joins the Rhine at Ragatz, 25 miles to the north. They were discovered towards the middle of the 11th century, and have been used ever since. Patiens used formerly to be let down by ropes, but they can now approach by a good road. The water (97° F.) is conducted in pipes to Ragatz, though there are bath-houses (1794) in the ravine. Near the village of Pfiffers (pop. 1628), which stands above and outside the ravine, is a Benedictine abbey, founded in the 8th century, but converted into a lucrative asylum after its dissolution in 1838.

Pfalz, the German name for the Palatinate (q.v.).

Pfalzgraff See Palatine.

Pfeiffer, Ida (née Reyer), a celebrated female globe-trotter, was born at Vienna, October 15, 1797. In 1820 she married an advocate named Pfeiffer, from whom she was obliged to obtain a separation. When she had settled her two sons in life, she proceeded to gratify, at the age of forty-five, her long-cherished inclination for a life of travel and adventure. Her first expedition was to the Holy Land in 1842. She tributed her eastern rambles in the following year, which, like all her other works, went through many editions, and was translated into French and English. In 1845 she visited northern Europe—Sweden, Norway, and Lapland. In 1847 Pfeiffer published her impressions in another book, Scandinavien und Island (2 vols. 1846). Resolving in 1846 on a voyage round the world, she started from Hamburg in a Danish brig for Brazil. She then sailed round Cape Horn to Chili, thence across the Pacific to the United States, and thence via the Mediterranean to France, and again embarked from Calcutta, via Persia, western Asia, southern Russia, and Greece, and re-entered Vienna in 1848. Two years later she published a narrative of her travels and adventures, entitled Eine Frauenfahrt um die Welt (3 vols. 1850). Meine Zweite Weltreise (1856) describes a second journey round the world from England by the Cape to Java, Borneo, California, Peru, and the United States (1851-54). In 1856 she set out on what was to be her last expedition—namely, to Madagascar. After enduring terrible hardships, she got away, and came home to Vienna—to die, October 29, 1858.

Pfeiffer, Otto, a great philosophical theologian of Protestant Germany, born at Stettin, near Cannstatt in Württemberg, September 1, 1838; studied under Ban, at Tübingen, from 1857 till 1861, and next paid a visit of study to England and Scotland; became pastor at Heilbronn in 1868, and superintendent at Jena in 1870, an office which he held the same year in exchange for the chair of Theology there. In 1875 he was called to be professor of Systematic Theology at Berlin. In New Testament criticism Pfeiffer belongs to the younger critical school which has grown out of the impulse given by Baur. But he is not the less an independent thinker, acute, suggestive, and profoundly learned, and he has made his name as well known in England and America as in Germany by a series of works which no serious student of philosophy or theology can afford to overlook. Of these the chief are Die Religion, die Wissen- schaft und Geschichte (2 vols. 1869; 2d ed. 1875); Der Paulinismus (1873; 2d ed 1890; Eng. trans. 2 vols. 1877); Religions-philosophie auf geschichtlicher Grundlage (2 vols. 1875; 2d ed. 1884-85; Eng. trans. 4 vols. 1890-92); Zur religiösen Verständ- lichung (1879); Die Wissenschaft der Geschichte und Stättelehre (1890; 4th ed. 1898); The Influence of the Apostle Paul on Christianity, the Hibbert Lectures for 1885; Das Unchristentum (1887); The Development of Theology since Kant (Lond. 1890); and The Philosophy and Development of Religion, the Gifford Lectures for 1884.

His brother, EDMUND PFIEFFER, born at Stettin 12th October 1842, studied at Tübingen, and after a short experience as a pastor was made professor of Philosophy at Kiel in 1873, whence he was called to Tübingen in 1877, where he has since then been a professor. He has written various studies on Leibnitz (1870), on Empiricism and Scepticism in Hume's Philosophy (1874), modern Pessimism (1875), Kantian criticism and English philosophy (1881), Arnold Geulinx (1884), Lotze (2d ed. 1884), Heracleitius of Ephesus (1890), &c.

Pforzheim, the chief manufacturing town of Baden, stands at the southern end of the Black Forest, 20 20 miles SE. of Karlsruhe by rail. It contains the remains of an ancient castle, from 1300 to 1553 the residence of the Margraves of Baden-Durlach, and was the birthplace of Rechlin. The town is famous for the manufacture of gold and silver ornaments, in which 8000 people are employed, and has further chemical and iron
Phaeodrus

Phaeodrus (or Phædrus, according to some scholars), author of a translation of Esop's fables in Latin verse, was, by his own account, a Macedonian, who from his childhood was trained in the Greek culture. While still young he came to Italy, and in Rome or some other city attended school where he studied Koinos, whom he quotes in the epilogue to his third book. From the title of the entire work, Phaedia Augusti Liberii Fabulæ, it appears that the stories have been arranged in the frequent order of the Alexandrian Mis, that is, of the Emperor Claudius, and that his brother Sejanus, the successor of Sejanus, either the first of that name or his successor Tiberius. Under the reign of this latter he published the first two books of his fables, but his biting though veiled allusions to the tyranny of the emperor (in the fable of the frogs asking a king) led to his minister Sejanus (in that of the jay dressed in peacock's plumage) caused him to be hated at court, then accused, and finally condemned—to what punishment is unknown. On the death of Sejanus he resumed publication, and dedicated his third book to one Empoleon, freedman of the Emperor Claudius, courting his protection from enemies and accusers. In the last years of his life, to which the fourth and fifth books belong, he seems to have regained liberty of pen as well as of person. He died probably at an advanced age. Phaeodrus was more than his claims to be—a reproduction of Esop; he invented fables of his own, and gave an Esopic turn to contemporary events. That the five books traditionally ascribed to him are his cannot with any large deductions be maintained—not a few of them may have been added as the Fabulae in their various common as an appendix to the five books, and found in an anthology attributed to Nicola Perotti, a scholar of the 15th century. The merits of Phaeodrus are his clear succinct narrative, his pure Latinity, and his skill in versification. Those who have put an end to all the doubts and finally of Müller have been ably cleansed by his latest and most helpful editor Ramorino (Turin, 1884).

Phæthon ('the shining'), in the writings of Homer and Hesiod, a frequent title of Apollo the sun-god, and subsequently employed as his name. Phæthon, in Greek mythology, is also the name of a son of Helios, famous for his unfortunate attempt to drive the sun's chariot. Seaward had the pre-

Phaecina. See Ulcers.

Phægeceytes, the white or colourless blood-corpuscles, which are also called leucocytes. They are active ameboid cells, and engulf both nutritive and harmful particles. Since the researches of Metchnikoff the physiological importance of these elements has been increasingly appreciated. Thus, it is generally recognised that the destruction of invading bacteria is due to the health and activity of the phagocytes. See Blood.

Phalacerobius. See Cormorant.

Phalanx, the Linear genus including Moths (q.v.).

Phalanger (Phalangista), a genus of small arboreal marsupials, of which many species are found in Australia and the islands to the north of it. All the species have long prehensile tails, and many grasp their food and convey it to the mouth with the forepaws. They feed usually on the young shoots and leaves of the trees in which they live, but in captivity they do not refuse animal food. The Vulpine Phalanger (P. vulpinus) is very common in Australia, and is used by the natives for food. The Dormouse Phalanger (P. mus), which is only six inches in length, resembles the common dormouse in habits and appearance. See also (under Flying Animals) FLYING PHALANGER.

Phalansterie. See FOURIER.

Phalax, the ancient Greek formation for heavy infantry, was a series of parallel columns standing close one behind the other, the whole owing to its depth of line and capable of penetrating any line of troops. The oldest phalax was the Lacedemonian or Spartan, in which the soldiers stood four, six, or, more generally, eight deep. The Macedonian phalax, the latest form, was sixteen men deep. The arms of the men were swords, shields, and long pikes or spears. The heavy-armed phalax was ordinarily flanked by peltastes or light infantry, similarly formed, who usually fought with javelins and slings.

Phalaris, tyrant of Agrigentum, in Sicily, who flourish about the middle of the 6th cent. B.C., was born on a small island near Cnidus, on the coast of Asia Minor, and whilst basking in the sun and enjoying the delights of the citadel of Agrigentum made himself master of the city. He greatly embellished it, and extended his power over large districts in Sicily. But after holding power for sixteen years he was overthrown, for his cruelties, by noble families of the island, and was soon after dead. The tradition points probably to the religious sacrifice of human victims to Ialor or Moloch (q.v.). Later ages represent Phalaris as a humane and enlightened ruler. But the 148 letters bearing his name were preserved by Bentley (q.v.) in 1657 and 1669 to be spurious, and to have been composed several centuries after Phalaris died. See Bentley's Dissertation, edited by W. Wagner (Lond. 1883).

Phalacrocorax. See Cormorant.

Phalaena, the Linear genus including Moths (q.v.).

Phalanger (Phalangista), a genus of small arboreal marsupials, of which many species are
when Mythology (q.v.) was universally considered to contain the teaching of ancient sages couched in the form of allegory, and everything in mythology was regarded as the offspring of fancy and hidden truth, phallic worship was naturally conceived to conceal some esoteric teaching as to the mystery of the transmission of life. But this view of mythology is dissipated by an examination of the manner of life and mode of thought of those savage peoples from the second to the 18th century, which, on the whole, was a practical one. The animal and vegetable, the plains and mountains, the2 were the centres of the inhabitants' attentions. They were not concerned with abstract ideas, but with practical matters, and their religious views were always practical. They believed in the existence of a god who could protect them and bring them good fortune. This god was worshiped in various ways, such as offering sacrifices, making offerings, and performing religious ceremonies. These practices were not seen as something abstract or theoretical, but as something that could bring them tangible benefits.

Phallus, a genus of fungi. See FUNGI.

Phalsbourg, or Pfalzberg, a town of Loraine, on the north-west arm of the Vosges, 25 miles N.W. of Strasburg. It was fortified by Vauban in 1680; invested, but not taken, by the Allies in 1814-15; and bombarded and taken by the Germans in 1870, after which they razed the fortifications. It was the birthplace of Eckermann, and is widely known through his travels and the other writings of the Eckermann-Chantren novels Pop. 3680.

Phanariots. See FANARIOTS.

Phanerogamia (Gr. phaneroe, 'manifest,' gamos, 'marriage') are those plants which bear flowers and produce seeds. But, for the differences and the resemblances between the flowering and seeding of these plants and the spores of Cryptogams, see CRYPTOZAMIA, FLOWER, GYMNOSPERMS, SEED.

The group includes the following sets of plants: A. Gymnosperms (q.v.), with naked ovules—e.g. conifers; B. Angiosperms (q.v.), with ovules enclosed in ovaries: (1) Monocotyledons (q.v.), with one cotyledon—e.g. lilies, grasses, orchids; (2) Dicotyledons (q.v.), with two cotyledons—e.g. buttercups, roses.

Pharaoh, the English spelling of the name given by the Hebrews to the monarch ruling in Egypt at the time, sometimes as if it were a proper name, though really an official title (from the Egyptian Peres or Pheres). The greatest difficulty that has been encountered in attempting to determine the particular monarchs who pass under this name in the Scriptures. See EGYPT.
was no need of any future reward. While the Pharisees held all the traditional ordinances in equal reverence with the Mosaic institutions, the Saddu- cees rejected, or rather varied some of these according to the traditions of their respective families, and treated religious observances, certain laws of purity, and some parts of the civil law. It may perhaps be assumed (as by Geiger) that the Pharisees were the representatives of a newer Halaeha, inspired by an oppositional attitude towards the national zeal and sentiment. Certain other legal differences between the two parties; such as the application of the laws of inheritance to daughters, or of the responsibility of the master for his servants, are nothing more than political party-views in a religious mask, which were meant to meet certain special isolated cases only. In general the Pharisees handled justice in a much milder manner than their antagonists, who took their stand upon the rigid letter, and would hear of no mercy where a violation of the osle was clearly manifest. Out of the midst of the Pharisees sprang the great doctors and masters of the Law (Heb. šopherim; Gr. nomoi<ıkaiou, ‘teachers of the law,’ usually rendered ‘scribes’), and to them were entrusted by the later rulers the most important offices. The greatest misconception has prevailed especially with respect to the coming together of these three groups, that of the Pharisees, Sadducees, and the general community as the ‘plague of Pharisaism.’ Pharisaism—from which gradually branched off the wld democratic party of ‘Zealots’ (Krutaim) in the revolution of Bar Cochba (q.v.)—has, from the final destruction of the commonwealth to this day, remained the principal representative of Judaism as a creed.

See JEWS, TALMUD; Schürer’s History of the Jewish People in the Time of Jesus Christ (Eng. trans. 5 vols. 1886-90).

Pharmacopoeia. This term has been applied to the regulation of the medical art in two respects: (1) a list of the articles of the Materia Medica, whether simple or compound, with their characteristics, their modes of preparation, and the tests for the determination of their purity; and (2) a collection of approved receipts or prescriptions, together with the rules for compounding articles in the Materia Medica. Almost every civilised country of importance has its national pharmacopoeia; those of the United States (6th ed. 1883), Germany (3rd ed. 1860), and France deserving special mention. The earliest pharmacopoeias were prepared by the Arabs from the 9th to the 12th century, and subsequently by the medical school of Salerno. The first pharmacopoeia published under authority appears to have been that of Nuremberg in the year 1542. Valerius Cordus, afterwards professor at Witten- berg, but then a student, showed a collection of medical receipts, which he had selected from the works of the most eminent writers, to the physi- cians of Nuremberg. The latter were so struck with its value that they urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the city council. Before this time the books chiefly in use among apothecaries were the treatises: On Simplex by Avicenna and Serapion; the Liber Serratoris of Baehdemon ben Aberazerim; and the Antidotarium of Nicolas de Salerno, arranged alphabetically. The work was commonly called Nicolaus Magnus, to distinguish it from an abridgment known as Nicolaus Pareus.

Confining our remarks to the British Pharmacopoeias, we may notice that the first edition of the London Pharmacopoeia (or, more correctly speaking, of the Pharmacopoeia of the London College of Physicians, &c.) was prepared chiefly on the works of Meuz and Nicolas de Salerno. Successive editions appeared in 1637, 1635, 1650, 1657, 1721, 1746, 1757, 1699, 1824, 1836, and 1851, and form an important contribution to the history of the progress of pharmacy and therapeutics, and to the development of the medical art. The nature and the number of the ingredients that entered into the composition of many of the pharmaceutical preparations of the 17th and 18th centuries would astonish most of the practitioners and patients of the present day. In the earlier serving, and dispensing of medicines. In sales.

The Edinburgh Pharmacopoeia is more modern than the London, the first edition having appeared in 1668, while the Dublin Pharmacopoeia date far back than 1807. The latest editions of these works appeared in the years 1841 and 1850 respectively.

Until the Medical Act passed in 1858, the right of publishing the pharmacopoeias for England, Scot- land, and Ireland was vested in the Colleges of Physicians of London, Edinburgh, and Dublin respectively; and as these three pharmacopoeias contained many important preparations, similar in name but totally different in strength (as, for example, dilute hydrochloric acid, solution of hydrochloraie of morphia, &c.), many publications arose from a London prescription being made up in Edinburgh or Dublin, or vice versa. By that act it is ordained that ‘the General [Medical] Council shall cause to be published, under their direction, a book containing a list of medicines and compounds, and the manner of preparing them, together with the weights and measures by which they are to be prepared and mixed; and containing such other matter and things relating thereto as the General Council shall think fit, to be called British Pharmacopoeia.’ And by a subsequent act it is ordained that ‘the British Pharmacopoeia shall for all purposes be deemed to be substituted throughout Great Britain and Ireland for the several above-mentioned pharmacopoeias.’ The British Pharmacopoeia, which appeared in the beginning of the year 1864, gave rise to such a general feeling of disappointment throughout the profession that the General Council brought out a new and amended edition in 1867. A second reprint with additions appeared in 1874. Another edition was published in 1885, and a supplement to it in 1890. There are also Homeo- pathic and Veterinary Pharmacopoeias (1813), and Pharmacopoeias for the London and other hospitals, but those are not printed by authority, nor authorised in any way by government.

The Pharmacopoeia of the United States is drawn up by a national convention consisting of delegates from the respective medical colleges, medical corpora- tions, and universities throughout the United States. It was first published in 1820, and a second edition appeared in 1828, but it is now revised every ten years, a new revision appearing in 1893.

Pharmacy, a department of the medical art which consists in the collecting, preparing, preserving, and dispensing of medicines. In almost Britain the practice of pharmacy is regulated by a
PHAROS

series of Pharmacy Acts, of which the more important are those of 1852, 1868, 1869, and 1882. See ADULTERATION, CHEMISTS AND DRUGGISTS, MEDICINE, PHARMACOPÆIA, PRESCRIPTION.

Pharos. See Alexandria, and LIGHTHOUSE.

Pharsalus, now Febrala, a town of Thessaly, to which were laid the first plain of the battle of the Salamis, and accordingly in the part of Thessaly restored to Greece in 1881; hence the Greeks had to retreat in April 1897. The district, Pharsalia, is historically notable mainly for Cæsar's great victory over Pompey, August 9, 48 B.C. See Lucanus.

Pharynx (Gr.) is the name of that part of the alimentary canal which lies behind the nose, mouth, and larynx. Its nature and functions are described in the article DIGESTION, where an illustration will also be found. In cases of Diptheria (q.v.) the pharynx is usually the chief seat of the disease. It is liable to ordinary inflammation or pharyngitis—an affection characterised by pain, especially in swallowing, without redness in the fauces or change of voice. Sometimes it proceeds to suppuration, and abscesses are formed. See QUINSY, THROAT.

Phascologale, a genus of marsupial quadrupeds allied to the Dasyures (q.v.), and containing, according to the most reliable estimate, thirty-five species, all of which are arboreal and insectivorous; they are spread through the Papuan islands and Australia. The best-known form is perhaps the 'Tapan Tafa' (P. penicillata), of the size and appearance of a rat, which commits depredations in the storehouses of Australian colonists, and is of the fiercest disposition when meddled with. This marsupial has a curious resemblance to the rodent genus Hapalotis, also found in Australia. It may be a case of ' mimicry ' between some of the species.

Phascolomyus. See WOMAATS.

Phases (Gr. phasis, 'appearance'), the different luminous appearances presented by the moon and several of the planets, sometimes the whole, a part, or none of the luminous surface being seen from the earth. See MOON, PLANETS.

Phasianidae. See PHEASANT.

Phasis, a river in Colchis, now called Rion or Paza. It rises in the Caucasus, and flows west into the Euxine near the ancient city of Phasis.

Phasme (Gr. phasma, 'a spectre'), a family of insects, including walking-stick insects (Bacillus and Bactaria), spectre-insects (Phasna), and leaf-insects (Phyllium). With the exception of Bacillus, which occurs in south Europe, they occur in the tropics—in South America, Borneo, East Indies, &c. As their names suggest, they have a striking resemblance to the twigs and leaves of the plants on which they feed and live. See LEAF-INSECT, MIMICRY.

Pheasant (Phasianus), a genus of gallinaceous birds of the family Phasianide; having a rather short crest, or line of black feathers in the skin surrounding the eyes destitute of feathers, and warty; the wings short; the tail long, its feathers so placed as to slope down, roof-like, on either side, the middle feathers longest; the tarsus of the male furnished with a spur. The males of all the species are brilliantly variegated; the female pheasants have shorter tails and dull or sombre colours. There are numerous species, natives of the warm and temperate parts of Asia. The Common Pheasant (P. colchicus) is said to have been brought from the banks of the Phasis, in Colchis, to the scenes of Europe, at a very remote period, its introduction being ascribed in classic legend to the Argonauts. From the Phasis it derived its Greek name Phasianus, the origin of its name in English and other modern languages. It was soon naturalised in Europe, and is now diffused over almost all the temperate parts of it. The date of its introduction into Britain is not known, but was certainly earlier than 1199, when King John granted William Brewer a licence 'to hunt the hare, fox, cat, and wolf, throughout all Devonshire, and to have free warren throughout all his own lands for hares, pheasants, and partridges' (Dugdale's Baronage, vol. i. p. 791). Strangely, however, the pheasant seems never to have been considered a royal dish till 1689. It has long been plentiful in plantations and game-preserves, and has been introduced into almost every part of the country suitable to its habits. The abundance of pheasants in Britain, however, is to be ascribed chiefly to careful game-preservation, without which the race would in all probability soon be exterminated. No kind of game fails so easily a prey to the poacher, for in its present method of rearing it is semi-domesticated, though we can hardly include it amongst our domesticated fowls.

A minute description of the common pheasant is unnecessary. The feathers on the upper part of the head are brownish green, with edgings of yellow; the neck has variations of green and blue, with reddish orange below; the breast and sides are variegated with brownish grey and purplish blue; the back and belly are variegated, the rump deep red with green and grayish reflections; the tail is dull greenish yellow, with yellowish grey, and bars of black, and a band of dull red on each side. The whole length of a male pheasant is about 3 feet, of which the tail measures about 18 inches. The entire length of the female is a little more than 2 feet, principally in that the tail is much shorter than in the male. The general colour of the female is pale grayish brown and yellow, variegated with darker brown, the sides of the neck tinged with red and green. The ordinary weight of a pheasant is about two pounds and a half; but when pheasants are abundantly supplied with food, and kept undisturbed, they are sometimes four pounds or four pounds and a half in weight. The pheasant, unlike the partridge, is polygamous.

The nest of the pheasant is on the ground, and is a rude heap of leaves and grasses, in which eleven or twelve olive-brown eggs are laid. But in the half-domesticated state in which it exists in many English preserves the pheasant does not pay that attention to its eggs and young which it does when more wild, and not unfrequently continues to lay eggs for a considerable time, like the domestic fowl; the eggs being removed by the gamekeeper, and hatched by hens, along with eggs from nests found

Common Pheasant (Phasianus colchicus), male and female.
among clover and hay in the season of mowing. In fact, where pheasants are reared in large numbers nearly all the birds are hatched by either common hens or hatched in the incubator, the object being for the purpose. In the former method coops are employed, in which there are runs formed by wire netting, and in this way a large number can be attended to at one time. Very young pheasants must be carefully supplied with ant's eggs, maggots, gypsy, and other insects and fruits of trees, until they are in their earliest stage. The difficulty of rearing birds bred in confinement has led to the introduction of various forms of artificial food, several of which are excellent. Custard is largely employed, and when given fresh is eaten with avidity, and brings on the young birds rapidly. Canary-seed is good also at first. Pheasants feed very indiscriminately on berries, seeds, roots, young shoots of plants, worms, insects, &c. Beans, peas, corn, and buckwheat are frequently thrown for them in open places in woods; and they scrape up bulbs and tawny roots in winter. They roost in trees at no great height from the ground, and pheasants sometimes capture them by burning sulphur below them. During the molting season they do not ascend trees to roost, but spend the night on the ground, when they fall a ready prey for foxes. They breed in the woods with a thick undergrowth, in which, when disturbed, they naturally seek shelter, running whilst it is possible, rather than taking flight. The male pheasant takes flight much more readily than the female, which, apparently instinctive to her brown colour to escape observation, often remains still until the sportsman is almost upon her. The males and females do not associate together except during the breeding season, but small numbers of one sex are often found in company.

The 'short crow' of the males begins in May. In Scotland pheasant-shooting legally begins on the 1st of October, and ends on the 3d of February. The pheasants turned out from the gamekeeper's breeding-yard into a preserve are in general supplied with abundance of food during winter, and come to the next season called as well as any kind of poultry, so that the sportsmanship of a Battue (q.v.), in which they are killed by scores or hundreds, is of the lowest kind. Maize is one of the best foods, but barley, peas, wheat, and oats, with the usual green food, are all employed. Some pheasants are supposed to have been produced by any kind of poultry, so that the sportsmanship of a Battue (q.v.), in which they are killed by scores or hundreds, is of the lowest kind. Maize is one of the best foods, but barley, peas, wheat, and oats, with the usual green food, are all employed.

Breeding: Pheasants are chiefly kept in aviaries as ornamental fowls, for which purpose they are well adapted. A recent introduction, the Prince of Wales Pheasant (P. pruinosus), was discovered on the Afghan frontier of India, and is distinguished from all other pheasants in that the greater part of its wings are white, though it is somewhat different in its markings and the arrangement of its colours.

See D. G. Elliot, Phasianides (1780–72), Tegetmeier, Pheasants (1875); Price, Pheasant-rearing (1888); Macpherson and others, The Pheasant (1895).

PHELS: Ephraim, an American author, was born 21st August 1844, at Andover, Massachusetts, the daughter of Professor Austin Phelps and of the authoress of Sunny Side. Besides lecturing and engaging in work for the advancement of women and for social reforms, she has written numerous juvenile works. The Journal of a Summer After (1868), which passed through twenty editions in the year of its publication; Beyond the Gates (1883); The Gates Between (1887); Hedged In and The Silent Partner (1870); The Story of Aris (1877); Doctor Zay (1884), in which the question of polygamy is powerfully handled; and The Forsaken (1890), in conjunction with her husband, the Rev. Herbert D. Ward, Come Forth, a travesty of the story of Lazarus, and The Master of the Magicians.
Phelps, Samuel, the last of the old school of actors, was born 13th February 1854 in Devonport. When seventeen years old he came to London, and was engaged on the Globe and Sun newspapers as reader; among his companions being Douglas Jerrold, then, like himself, a stage-struck youth. After some years spent in the York circuit in the autumn of 1856, and continued in the provinces for eleven years. On 28th August 1857 he made his debut in London as Shylock at the Haymarket, under the management of Barham and Williams, making a very great success. He was afterwards engaged by Macready, but his genius did not get full scope until the beginning of his famous Sadler’s Wells management, one of the most extraordinary achievements in the history of the drama. At an outlying unfashionable and unpopular theatre he for eighteen years produced a constant succession of ‘legitimate’ plays, attracting around him an excellent company, and educating a rough and unpolished audience to appreciation of the masterpieces of English dramatic literature. He began this apparently unpromising enterprise at the end of 1854, continued as manager till March 1862, and made his last appearance before his Islington friends on 6th November 1862. During his management he produced no fewer than thirty-one Shakespearean plays, as well as works of the other great Elizabethans, and of the dramatists of the 18th century. Being engaged to Colman after leaving Sadler’s Wells Phelps did not attach himself to any particular theatre, appearing at Drury Lane, the Queen’s, and the Gaiety theatres, and playing regularly in the provinces. On 1st March 1878, when acting Wolsey at the Aquarium (Imperial) Theatre, he broke down, and never played again. He died on 6th November 1878. Although primarily a tragedian, Phelps was an excellent all-round actor, and some of his comedy parts are among his most notable—as, for instance, Malvolio, Baitoum, i.e. Shallow. In tragedy he was famous in Wolsey, Lear, Macbeth, Brutus, Luke (City Madman), and Sir Giles Overreach; while among his other chief successes were Richelieu, Sir Pertinax Macysophant, Bertuccio, Ohi Dormont, and Job Thornebery.

Phenacodoe, by J. and E. Coleman (1880); and Life and Letters, by W. May Phelps and John Forbes Robertson (1886).

Phenacit, a drug prepared from carbolic acid, valuable in fevers, and, like antipyrin, of service in stilting pain and securing rest in cases of severe headaches, insomnia, and nervousness.

Phenacodins. See MAMMALS.

Phenol. a name for Carbolic Acid (q.v.). See also AROMATIC SERIES; and for the Phenol Dyes, DYEING, Vol. IV. p. 141.

Pherec, a powerful city of Thessaly, near Mount Pelion; according to legend, the ancient royal seat of Acredus and Acoleus, and after- wards of political consequence under ‘tyrants’ of its own, who long made their influence felt in the affairs of Greece, and repeatedly attempted to make themselves masters of Thessaly. One of these tyrants, Alexander (slain 357 B.C.), is par- ticularly celebrated for his cruelties.

Pherecydes, an ancient Greek philosopher, born in the island of Syros, in the 6th century B.C., author of the Politeia. He taught the doctrine of the existence of the higher soul after death; but it is uncertain if he held the doctrine of the transmigration of souls, afterwards promulgated by his disciple, Pythagoras. Of his work, a mythological system of philosophy, only frag- ments are extant, collected and edited by Sturz (2d ed. Leip. 1824).—Another Pherecydes, a native of Leros, who lived in the 5th century B.C., com-

Phidias (Gr. Φιδίας), the greatest sculptor of ancient Greece, was born the son of Charimdes, at Athens about 500 B.C. His instructor in sculpture was Ageleus of Argos. To Phidias came an opportunity such as falls to the lot of few artists: Pericles, having risen to the head of affairs in the Athenian state, devoted to the adornment of the temples and other public buildings fitting for the vanquisher of Persia, and he not only gave to Phidias a commission to execute the most splendid statues that were to be erected, but made him general superintendent of all the public works planned for the city. Phidias was to execute for the Parthenon at Athens, a vast colonnade of Doric columns, the frieze of the Temple of Zeus at Olympia, a series of small statues for the Parthenon, a vast marble statue of Nike on the Acropolis, a great golden statue of Athena on the Acropolis, and a colossal figure of Athena Promachos on the Acro- polis at Athens, a great golden statue of Athena Promachos on the Acropolis at Athens, a monument of the victory of Marathon at Delphi.
PHILADELPHIA

and numerous others. Their prevailing characteristics appear to have been an ideal simplicity, and every piece relays that we possess are the most noble specimens of sculpture in the world. In 1888 there was dug out at Tanagra a red vase bearing what was believed to be the signature of Phidias. See SCULPTURE.

See A. S. Murray, Greek Sculpture (1880); G. Waldstein, Essay on the Art of Phidias (Camm. 1883); and Cobden, Phidias (Paris, 1886).

Phialgia, an ancient town of Arcadia, situated in its extreme south-west corner. From its temple of Apollo, at Basse, 5 to 6 miles distant, a sculptured frieze representing the contests between the Centaurs and Lapithes, and the Amazons and Greeks, was sent to the British Museum in 1812. The temple was first described by Chantler in 1765. Next to the Theseum at Athens it is the most perfect architectural ruin in all Greece, being built of fine gray limestone and white marble. It was designed by Ictinus, one of the architects thus the Parthenon at Athens, and originally 125 feet long and 43 broad, and had 15 columns on each side and 6 at each end, in all 33, of which 31 still stand. See Cockerell, Temples of Agina and Bucea (1860).

Philadelphia. See HIGHLAND COSTUME.

Philadelphia, the chief city of Pennsylvania and the third city of the United States in population, is bounded by the Schuylkill River, about 100 miles (vai Delaware Bay River) from the Atlantic Ocean, 90 miles by rail SW. of New York City and 136 miles NE. of Washington, D.C. Philadelphia is a city of Philadelphia, is a city lying along the Delaware from the mouth of the Schuylkill River at League Island, northward, for about 15 miles, and has an average breadth of some 8 miles. Its total area embraces nearly 130 sq. mi., about one-eighth of which is comprised within the limits of the thickly built up portions of the city, while the rural sections consist of suburban communities, which, though within the city limits, are locally known by the names they bore prior to their annexation to the city. Philadelphia is notably a city of homes.
Medical College (1869), the Medico-Chirurgical College (1880), the Woman's Medical College (1850), and the Philadelphia Polyclinic and College for Graduates in Medicine.

Manufactures, Commerce, &c.—Though in its early history Philadelphia was renowned for its extensive shipping interests, as compared with those of its sister cities, it is rather as a manufacturing than as a commercial city that Philadelphia holds a present prominence. Here are immense establishments covering acres of ground, from which millions of dollars worth of products are issued annually for the home and foreign markets, besides smaller concerns innumerable. The aggregate capital employed in manufacturing is estimated at $300,000,000, the number of hands employed at 250,000, and the value of the annual product at $600,000,000. Among the prominent industries of this class are the building of locomotives, of which $10,000,000 worth are constructed annually, employing some 5000 men; the manufacture of carpets, at which about 30,000 hands are employed, producing annually goods valued at about $50,000,000; woolen and worsted goods, employing 35,000 hands, and valued at $45,000,000; upholstery goods, valued at $25,000,000; cotton goods, $15,000,000, &c. General iron, steel, and steel products are computed to employ 40,000 hands, whose product reaches $75,000,000 in value—the single article of saws, principally made by one firm, giving employment to 500 workmen, and amounting in value to $28,000,000. There are several extensive sugar-refineries, oil-refineries, breweries, and great chemical works. The Commercial Museum, organised under ordinance of Philadelphia councils, collects trade samples of goods made and sold abroad, and of the natural products of foreign countries, and supplies information about foreign commerce and commercial openings, with especial reference to American exports.

The value of the exports for the fiscal year 1889-90 was $16,927,610; for 1879-80, $14,940,023; for 1869-70, $27,410,583. The imports for 1869-70 were valued at $14,433,211; for 1879-80, $35,944,500; for 1889-90, $33,936,317. In 1897 the total value of the foreign trade of Philadelphia was $86,496,042, including exports and imports; in the same year 5906 vessels entered and 5904 cleared the port.

Eminent Philadelphians have been: John the explorer; General McClellan; Dr Morton, of anaesthetic fame; the actors Elwin Forrest, Joseph Jefferson, and Hermann Vezin; Henry George; Charles Hodge; C. G. Leland; Kate Douglas Wiggin; and Frank Stockton.

The city government is almost entirely administered by the mayor through various departments—of public works and of public safety; each administered by a director who is appointed by him; of receiver of taxes, of city treasurer, of city controller, and of law, whose heads are elected for three years; a department of education governed by a board of 38 members (one from each city ward), whose members are appointed by the judges of the courts, and who serve without compensation; a department of charities and correction, whose officials are appointed by the mayor, and who serve without compensation; and a sinking fund commission. The legislative branch of the city government consists of a council of 38 members (one from each ward), who are elected for three years, and a chamber of common council of 135 members, who are elected for two years, all of whom serve without pay. The judiciary of the city and county consists of twelve judges of the Courts of Common Pleas and four judges of the Orphans' Court, all of whom are elected for ten years. There are besides twenty-eight magistrates elected for five years.

Founded in 1852 (see PENN), Philadelphia the year after was made the capital of Pennsylvania, and soon became a place of importance. It was the central point in the war of independence, and the city still preserves the Carpenters' Hall (1770), where the first congress met (4th September 1774), and the old State House (1735), with its Liberty Bell, where the Declaration of Independence (see INDEPENDENCE DAY) was adopted in 1776, and which has since been famous as Independence Hall.

At Philadelphia, moreover, the federal union was signed in 1778; and here, too, the constitution was framed, in 1787. An interest of another kind attaches to the fact that the Protestant Episcopal Church of North America was organised here in 1766. From 1790 to 1800 Philadelphia was the federal capital; and the first mint was established here in 1792. Later events have been the holding of the Centennial Exhibition, in 1876, and the commemoration of Penn's visit, in 1882. Pop. (1700) 4500; (1800) 76,250; (1860) 568,034; (1880) 847,170; (1890) 1,046,964; (1900) 1,295,997.

See Schard and Thompson's History of Philadelphia (3 vols. 1884); Philadelphia and its Environs (Lippincott, 1896); and works by Hazard (1879), Westcott (1877), Cook (1882), Woolsey (1888), and Agnes Repplier (1889).
Philadelphia, in Asia Minor. See Alabster.

Philadelphia, a mystic sect emphasizing 'brotherly love' (Gr. philadelphia), founded in London in 1692 under the influence of Boehme by Dr John Pordage (1608-98) and Mrs Leaule and others. It had for a time a branch in Holland, but disappeared early in the 18th century.

Philemon, a short epistle addressed to Philemon, a man of wealth and liberality, who had been a convert of the apostle, and is now addressed by him as his fellow-worker. It was at Philemon's house, and perhaps under his presidency, that the Christians of Colossae held their meetings. In the Apostles' Constitutions he is represented as bishop of Colossae, and subsequent tradition has it that he suffered martyrdom there under Nero. Philemon had possessed a slave called Onesimus, who, after losing his master, had run off and found his way to Rome (or Cassarae), where there had been an influence under the influence of Paul, and been converted to Christianity. At first the apostle seems to have been minded to retain Onesimus for his own service, but on further consideration he resolved to send him back to his former master, and accordingly made him the bearer of the epistle before us, in which Paul the aged asks pardon for the runaway, and entreats the injured master to receive him 'not now as a servant, but above a servant, a brother beloved.' The epistle exhibits fine delicacy and tact throughout, and has been characterised by Renan as 'one of the most exquisite in the New Testament.' Its genuineness may be said to be well established. Some writers, indeed, in the fourth century held that it was too trifling and unedifying to have been written by Paul; but the arbitrariness of this criterion was pointed out by Jerome, Chrysostom, and others. Baun also regarded it as a literary invention intended to illustrate the ideal relation of master and slave; but this view is not strongly urged by any of the expositors, while some of them (Hilgenfeld and Holtzmann) have entirely abandoned it. There are commentary notes on the Epistle to Philemon by Meyer, Bleek; Elliott (Philothea, Colossians, and Philemon, 3d ed. 1863), and Lightfoot (Colossians and Philemon, 7th ed. 1884).

Philemon and Baucis, according to a classic myth, finely poetised by Ovid in his Metamorphoses, were a married pair, remarkable for their mutual love. Jupiter and Mercury, wandering through Phrygia in human form, were refused hospitality by every one, till this aged pair took them in, washed their feet, and gave them such humble fare as they could provide. On going away, the gods took them with them to a neighbouring mountain, on looking from which they saw their village covered with a flood, but their own cottage changed into a splendid temple. Jupiter permitted them to make any request they chose, but they only asked to be servants of his temple, and that they might die at the same time. When, accordingly, they were seated at the door of the temple, being now of great age, they were changed, Philemon into an oak, and Baucis into a linden.

Phildor, the assumed name of a French family, originally called Danican, which has produced several distinguished musicians, and a composer, François André (born at Dreux in 1726, died in London, 1785), who was even more famous as an authority on Chess (q.v.). See Allen's Life of Phidilor (Philb. 1864).
Philip of Macedon, the father of Alexander the Great, was born at Pella in 382 B.C. He was the youngest son of Amyntas II. and Eurydice, and spent part of his early life as a hostage at Thebes. The assassination of his eldest brother, Alexas, in 359 B.C., made him heir to his throne. His second brother, Perdiccas III., in battle (369 B.C.), made him guardian to his nephew Amyntas, still an infant; but in a few months Philip made himself king, the rights of Amyntas being set aside. Dangers soon beset him from without and from within. He was young and inexperienced, and soon disappeared before the decision, the energy, and the wise policy of the young king. In the brief space of a year he had secured the safety of his kingdom, and had gained for himself a dreaded name. Henceforward his policy was one of aggression. The Greek towns on the coast of Macedonia were the first objects of attack. In Thrace he captured the small town of Crenides, which under its new name, Philippi, soon acquired great wealth and fame. The surrounding district was rich in gold-mines, which proved a source of great revenue to Philip for the rest of his life. He next turned his attention to the means of paying his armies, and of bribing traitorous Greeks to open the gates of many cities. After a few years of comparative leisure he captured Methone (at the siege of which he lost an eye); next year he entered Thessaly, forced the Pass of Thermopylae, which, however, he did not attempt to force, as it was strongly guarded by the Athenians. He therefore directed his arms against the Thracians. After capturing all the towns of Chalcidice—the last of which was the important Thasus—Philip, in 356 B.C., joined himself to the king of the Thracians, and next year with the Athenians, who had been at war with him in defence of their allies the Olynthians. It was this siege of Olynthus by Philip which called forth the famous Olynthian orations of Demosthenes. Philip was now regarded by the Thessalians as their conqueror. His next step was to secure a footing in the Peloponnesus, by expelling the cause of the Argives, Messenians, and others against the Spartans. In 339 B.C. the Amphictyonic Council declared war against the Locrions of Phocis, domestic war with Phocis and his relations in Thrace, and next year Philip captured Phocis, destroyed its cities, and sent as colonists to Thrace many of the inhabitants (346 B.C.); and he was appointed, jointly with the Thebans and Thessalians, king of Thessaly. Philip's next act was to guard against war with Persia. He now made war on the Persian king, chose Philip as leader of their armies. Preparations were in progress for this great expedition when he was suddenly cut off by the hand of the assassin Pausanias, at a festival to the god at Gaugamela, and the terms of his marriage with Dorothea of Ephesus (336 B.C.). Philip was a man given to self-indulgence and sensuality; he was faithless in the observance of treaty obligations, and inscrupulous as to the means by which he gained his ends; but of his energy, acuteness, and eloquence it is impossible to speak too highly. He was at the same time a lover of learning and a liberal patron of learned men. See works cited at Greece and Demosthenes.

Philip II., better known as Philip-Augustus, king of France, was the son of Louis VII. and Alix of Champagne, and was born in August 1163. He was crowned joint-king in 1179, during the lifetime of his father, succeeded him in 1180, and proved a great and able monarch of the Capet dynasty, while he confirmed his hold of the throne by marriage with Isabella of Hainault, the last direct descendant of the Carolingians. His first war, made upon the Count of Flanders, gave him the county of Vermandois and the city of Lille. He invaded Italy, and, by his marriage with Berta of Meissen, despoiled the Jews, and reduced the rebellions Duke of Burgundy to submission. He supported the sons of Henry II. of England in their rebellions against their father, and gained Berri by cession in 1180. On the accession of Richard to the throne Philip and he set out together on the third crusade, but they quarrelled while wintering in Sicily. After staying but three months in Syria he returned to France, having taken a solemn oath not to molest Richard's dominions; but no sooner had he returned than he made a bargain with the faithless edward the Confessor of England to share the kingdom. The fiery Richard's sudden return occasioned an exhausting war, which was closed through the mediation of Pope Innocent early in 1190. Richard died within two months after; but Philip did not hasten an end, on account of the rival claims of John and his nephew Arthur of Brittany to the French heritage of King Richard, which consisted chiefly of Anjou, Maine, and Touraine. Philip embraced the cause of Arthur, but was for a while fully occupied by his quarrel with the pope. He had put away his second wife, Ingeborg of Denmark, in order to marry the beautiful Agnes of Meier, but the terror of the thunder of the Vatican forced him to replace Ingeborg upon his throne. The murder of Arthur again gave him the excuse he sought. Richard's great fortress of Chateau Gaillard fell early in 1204, and Philip passed in triumph over Normandy. Before the end of that year he had added to his dominions Normandy, Maine, Anjou, and Touraine, with part of Poitou, as well as the over-lordship of Brittany, with a fief of Normandy. Philip took no active part in the wars of the English against the French, and devoted himself to consolidating his dominions. The great victory of Bouvines (20th August 1214) over the Flemish, the English, and the Emperor Otto established his throne securely, and the rest of his reign was devoted to enlarging his empire, administrating justice and to the building and fortifying of the city of Paris. Notre Dame and the great court of peers remained last monuments of this great king's administration. He died at Monts, July 14, 1223.

See works by Capetique (3d ed. 2 vols, Paris, 1842), Mazarran (Lille, 1878), and Davidson (Stuttgart, 1888).

Philip IV., surnamed Le Bel or 'the Fair,' king of France, the son of Philip III., the Rash, and Isabella of Aragon, was born at Fontainebleau in 1298, and succeeded his father in 1285. By his marriage with Queen Johanna of Navarre in 1254, he obtained Navarre, Champagne, and Brie. He overran Flanders, but a Flemish revolt broke out at Bruges, and at Courtrai on the Day of Spurs the flower of the French chivalry went down in thousands before the sturdy burghers. The great event of his reign was the marriage of his daughter Marie to Boniface VIII., which grew out of his attempt to levy taxes from the clergy. By the bull Clerici laicos in 1296 Boniface forbade the clergy to pay taxes, and to this Philip replied by forbidding the expenditure of money or valuables, thus cutting off a main supply of naval revenue. A temporary reconciliation in 1297 was ended by a fresh outbreak of the quarrel in 1300. Philip flung
the papal legate into prison, and summoned the three Estates of France, clergy, nobles, and burghers. The last two assured him of their support even in case of excommunication and interdict. Boniface replied with the celebrated bull *Unam Sanctam*. Philip, enraged by the bull, dissolved the Parliament, and the consent of the States-General conferred the property of those prelates who had sided with the pope. Boniface now excommunicated him, and threatened to lay the kingdom under interdict, but the king sent to Rome William de Nogaret and did not seize any prelate in aid of the Colonnas. Though released after a few days by a popular rising, Boniface soon afterwards died. In 1355 Philip obtained the elevation of one of his own creatures to the papal chair as Clement V, and placed him at Avignon, beginning the seventy years' captivity. He expelled the unhappy and reluctant pope to condemn the Templars in 1310, and to decrees the abolition of the order in 1312. In spite of skilful defence, they were condemned and burned by scores (see TEMPLARS), and thus exemplified by God. The grand master, Jacques de Molay, was burned 18th March 1314, and at the stake he summoned Philip to co-operate within a year and a day, and the pope within forty days, before the judgment-seat of God; strange to say, both pope and king died within the latter term of containment. November 29, 1314. Philip during his whole reign steadily strove for the suppression of feudalism and the introduction of the Roman law; but while thus increasing the power of the crown, and also that of the third estate, he converted royalty, which was formerly protecting, kind, and paternal, to the mass of the people, into a hard, avaricious, and pitiless task-master. Under him the taxes were greatly increased, the Jews persecuted, and their property confiscated; and, when these means were insufficient to satisfy his avarice, he caused the images 'greatly deformed.'

**Philip VI.** of Valois, king of France, was the son of Charles of Valois, younger brother of Philip IV., and succeeded to the regency of France on the death of Charles IV. The proclamation of a king was deferred on account of the pregnancy of Charles IV.'s widow; but on her giving birth to a daughter, the deceased child was beheaded, and the king at Rheims (May 29, 1328). His right to the throne was denied by Edward III. of England, the grandson of Philip IV., who declared that females, though excluded by the Salic law, could transmit their rights to their children, and therefore insisted upon the superiority of his own claim. Philip, however, was not only already crowned king, but he had the support of the people. His reign commenced gloriously; for, marching into Flanders to support the count against his rebellious subjects, he encounteredPhilip, the prince of Constance by vanquishing the Flemings at Cassel (August 23, 1328). He was obliged to give up Navarre (q.v.), as the Salic law of succession did not apply to it, but he retained Champagne and Brie, paying for them a considerable annual stipend. The hundred years' war with England began in 1337 both in Gienne and in Flanders, but was carried on languidly for several years, the only prominent incident being the destruction of the French fleet off Shys (June 24, 1340). Philip was a bad and faithless man, and his grasping extortion well-nigh exhausted the wealth of the country. Yet, in the midst of his pleasures and for new wars had constantly to be provided by some new tax or fresh confiscation. In 1346 Edward III. landed in Normandy, ravaged the whole country to the environs of Paris, and totally defeated Philip at Crécy. A truce was then concluded, but the devoted kingdom had no sooner been released from war than death threatened in the yet more terrible form of the 'Black Death.' Philip received Dauphine in gift in 1349, purchased Majorca from its unfortunate king, and died August 22, 1350, neither loved nor respected.

**Philip II.** king of Spain, the only son of the Emperor Charles V. and Maria of Aragon, was born at Valladolid, 21st May 1527. He was brought up in Spain, and carefully educated for his destiny, but grew up distrustful and reserved; cold and austere, without being virtuous; haughty and bigoted, yet without real respect for honour or religion. He eloped in 1554 he married the ill-fated Don Carlos. In 1548 he went to join his father at Brussels, and made a decidedly unfavourable impression upon his future subjects. Three years later he returned to Spain, and in 1554 he made a marriage of policy with Mary Tudor, Queen of England. During his fourteen months' stay in England he laboured hard but unsuccessfully at the unremunerative task of ingratiating himself with his wife's subjects. His failure, together with the vexations jealousy of a wife who was far from chaste, as well as the death of his only forty, and even all male heir, prompted him to leave England and return to Brussels (September 1555). In the next half-year he became by the abdication of his father the most powerful prince in Europe, having under his sway Spain, the Two Sicilies, the Marian, the Low Countries, Franche Comté, Lorraine, and the Duchy of Savoy, with the best disciplined and officered army of the age. The treasury alone was deficient, having been drained by the enormous expenditure of his father's wars. The first danger he had to face was a league formed between Henry II. of France and the Emperor Charles V. and Philip the Second of Spain, his Italian dominions. Alva soon overran the territories of the pope, while Philip's army under Philip of Savoy defeated the French at St Quentin (August 10, 1557) and Gravelines (July 13, 1558). These reverses forced Henry II. to agree to terms of peace at Cateau Cambreins (April 2, 1559). In January 1558 the French had captured Calais, and Mary Tudor's death followed eleven months later. Her husband, after an unsuccessful attempt to obtain the hand of Queen Elizabeth, married Isabella of France (June 24, 1558) and returned to Spain, where he lived the rest of his life.

The main object of his domestic policy was to concentrate all power in himself, and to this end he laboured to destroy everything resembling free institutions in any of his dominions. He estima-

### Philip VI. of Spain

**Philip II. of Spain**

- Born: 21st May 1527
- Father: Don Carlos
- Geographic areas: Spain, Two Sicilies, Marian, Low Countries, Franche Comté, Lorraine, Duchy of Savoy
- Married: Mary Tudor, Queen of England
- Reign: 1554-1555
- Death: 10th August 1555

- **Role**: Major military and political influence during his reign.
- **Policy**: Emphasized centralized power and religious conformity.
- **Legacy**: Under his rule, the Habsburgs expanded their territories.

**Philip II. of France**

- Born: 29th May 1324
- Father: Philip V.
- Geographic areas: France, Champagne, Brie
- Reign: 1328-1350
- Death: 22nd August 1350

- **Role**: Known for his role in the Hundred Years' War and his capture of Calais.
- **Policy**: Focused on internal peace and the suppression of feudalism.
- **Legacy**: Reign marked by the Hundred Years' War and the weakening of the French monarchy.
The one great triumph of his reign was the famous naval victory of Lepanto (September 17, 1571), won by his half-brother, Don John of Austria, over the Turks off of Dalmatia. Spain was now far from having become extinct, Philip laid claim to the throne, and despatched Alva to occupy the kingdom. But his attempt to conquer England recoiled upon himself in hopeless disaster, as the ships of the great Armada were swept to destruction by tempests and the contemptible value of the English seamen. His intrigues against Henry of Navarre were foiled by his antagonist's courage, aided by the death (1592) of his own general Alexander Farnese and Henry's politic change of his religion. The stubborn resistance of the Netherlands and the exasperating ravages of the English cruisers on the Spanish Main, added to financial distress at home, embittered the last years of Philip, and he died of a lingering and peculiarly bathsome disease, in the Escorial at Madrid, on 13th September 1598, under the shadow of that failure which had followed all his greatest undertakings. Philip II. possessed great abilities, but little political wisdom, and he engaged in so many vast enterprises at once as to overtask his resources without leading to any profitable result. A great love and fear of war, and jealous in temper, he persecuted all heretics through the Inquisition with relentless cruelty, and at the same time dealt a fatal blow to Spain by crushing that ancient, proud, and chivalrous spirit which had been the secret of its strength, as well as the commerce of the country, by oppressive exactions and by a bitter persecution of the industrious Moriscos. There is hardly a more unlovable figure in history than this sullen and solitary bigot whom historians with unusual unanimity have united to condemn.

See the articles ALVA, THE DUKES OF ANJOU, CHARLES V., CARLOMART, HOLLAND, AND SPAIN; THE HISTORIES OF FRESCOET, MOLEY, AND FRIENTRE; Mignet's Antonio Perez et Philippe II. (5th ed. 1881); Fernandez's Histoire de Philippe II. (3d ed. 4 vols. 1887); Gachard's two books on Don Carlos, and his editions of the correspondence of Philip (1848-89). The many good points of Philip's character are brought out in Froude's Spanish Story of the Armada (1892) and Martin Hume's monograph on Philip (1897).

Philip V., king of Spain, and the founder of the Bourbon dynasty in that country, was the second son of Philip IV. (who was Louis XIV. and Maria Theresa of Spain) of France, and was born at Versailles, December 19, 1683. In 1700 Philip, then Duke of Anjou, was bequeathed the crown of Spain by Charles II. His grandfather, Louis XIV., as he left him to take possession of the throne, uttered the famous phrase, 'Mon fils, il n'y a plus de Pyrenees.' He entered Madrid in February 1701, and after a long and varying struggle against his rival, the Archduke Charles, was left in possession of his throne by the peace of Utrecht (1713). Next year died the queen, Maria Luisa, daughter of Victor Amadeus, Duke of Savoy, whom Philip had married in 1702; and soon after he married Elizabeth Farnese of Parma, 'the termagant,' in Carlyle's phrase, who embalmed the pride of Europe for thirty years. By her he fathered a son, who was united by the amiable and weak-minded king to Alberoni. Philip was obliged by the Quadruple Alliance to dismiss his daring and ambitious minister at the close of 1718. He abdicated in favour of his son, Don Louis in 1724, but renewed the crown on the death of his half-brother in 1731. The ambitious queen's dearest wish was to drive the Hapsburgs out of Italy in the interests of her sons by a former marriage, but all her efforts succeeded only in securing the Two Sicilies for Don Carlos. Spain joined the coalition against Maria Theresa, and her younger son Don Philip was at first successful in conquering the Milanese; but as soon as the Silesian war was closed by the treaty of Dresden the Austrian queen poured her troops into Italy and drove out the Spaniards. At the crisis Philip, who had been for years sunk in a state of mental stupor, died at Madrid, July 9, 1746. See ALBERONI, Succession Wars, and Spain; and Baadrllari's 'Henry the Fourth, and the Cour de France, 1700-17 (2 vols. 1890-91).

Philip, surnamed of the Wampaug tribe of Indians, was the second son of Massassquat, who for nearly forty years had been the first and staunchest ally of the Pilgrim settlers of Plymouth, and had obtained English names for his two sons. In 1661 Philip succeeded his brother, and formally renewed the treaties of 1644 and 1646. By 1671, however, goaded by the encroachments of the whites, he had formed a confederation of tribes aggregating nearly 10,000 warriors; and in 1675 what is known as King Philip's War broke out. On the Indian side it was a war of surprises and massacres among the towns, which were swept by 600 colonists. In December 1675 Governor Winslow and a force of 1000 men burned the great fort of the Narragansets, swept 600 warriors, and massacred 1000 women and children. In the spring the Indians retaliated for a time, but their numbers steadily diminished after several trials of force, and within five years the confederation; others, littiseral to neutral, declared against them. In the early summer Philip's squaw and little son were captured, and sold as slaves for the West Indies; and on 12th August 1676, at midnight, he and his remaining followers were surprised by Captain Benjamin Church. Philip was slain, and his head cut off. Afterwards his body was drawn and quartered, and the head was exposed on a gibbet at Plymouth for twenty years. Church wrote an Entertaining History of King Philip's War (1715); a new edition of it was published by S. G. Drake, Boston, 1825; see also Washington Irving's Sketch-book.

Philip the Bold (Philippe le Hardi), the founder of the second and last ducal House of Burgundy, was the fourth son of John the Good, king of France, and his wife Constance of Luxembourg, and was born January 15, 1342. He was present at the battle of Poitiers (1356), and with his heroic courage saved his father's life to save his father's, as earned him the epithet of le Hardi, or the 'Bold.' He shared his father's captivity in England, and on returning to France in 1360 received in reward of his bravery the duchy of Touraine, and in the death of his father, the duchy of Burgundy, which he divided in 1369. In 1367 he commissioned with success against the English, and in 1380 he helped to suppress the sedition of the Flemish towns against their count, his father-in-law. But the citizens of some of the populous places, especially Ghent, were possessed with such a fever of independence that they were only brought back to their allegiance after the bloody defeat of Rosbeek (November 27, 1382), when 26,000 Flemings were left on the field. Flanders, the county of Burgundy, Artois, Béthu, and Nevers fell, and he by the defeat of the French at 1384, and his firm and wise government quickly won the affection and esteem of his new subjects. He encouraged judiciously arts, manufactures, and commerce, and his territory—a kingdom in extent —was one of the best governed in Europe. During the minority and subsequent infirmity of his
nephew, Charles VI, of France, he was obliged to take the helm of affairs, and prepare the state from internal condition within and the attacks of the English without. He died April 27, 1404.

**Philip the Good** (Philippe le Bon), Duke of Burgundy, the son of Jean 'Sans-pear' by Margaret of Bavaria, and grandson of Philip the Bold, was born at Dijon, the capital of the duchy, June 13, 1363, and, on the assassination of his father on the bridge of Montreueu at the instigation of the dauphin (afterwards Charles VII.), succeeded to the duchy of Burgundy. Bent on avenging the murder of his father, he entered into an offensive and defensive alliance with Henry V. of England at Armstrong in 1419, at the same time insinuating him as the rightful regent of France, and heir to the throne after Charles VI.'s death. This agreement, which disregarded the Salic law, was sanctioned by the king, parliament, university, and States-general of France in the treaty of Troyes (1420), but the dauphin declined to resign his rights, and took to arms; he was, however, defeated at Crevant (1423) and Verneuil (1424), and driven beyond the Loire. Some disputes with the English prompted Philip to conclude a treaty with the king of France in 1429. However, the English, by ceding to him the provinice of Champagne, and paying him a large sum of money, gained him back to their side. At this time, by falling heir to Brabant, Holland, Zealand, and the rest of the Low Countries, he was at the head of the most flourishing and powerful realm in western Europe; but though much more powerful than his predecessor, the king of France, he preferred to continue in nominal subjection. Smarting under some fresh insults of the English viceroy, and strongly urged moreover by the pope, he made a final peace (1435) with Charles, who gladly accepted it even on the hard conditions which the French proposed. The English, in revenge, committed great havoc among the merchant navies of Flanders, which irritated Philip to such an extent that he declared war against them, and, in conjunction with the king of France, gradually expelled them from their French possessions. The imposition of taxes, which were necessarily heavy, excited rebellion, headed, as usual, by the citizens of Ghent, but the duke inflicted upon them a terrible defeat (July 1434), though he went over a victory bought with the blood of 20,000 of his subjects. The latter part of his reign was filled with troubles caused by the quarrels between Charles VII. and his son, the Dauphin Louis (afterwards Louis XI.), who had fled from his father's court, and sought shelter with Philip, although, after ascending the throne, far from showing gratitude, he tried in the most dishonourable manner to injure his benefactor. Philip died at Bruges, July 15, 1467, deeply lamented by his subjects. Under him Burgundy was the most wealthy, prosperous, and tranquil state in Europe; its ruler was the most feared and admired sovereign of his time, and his court far surpassing its monarch those of his contemporaries. Knights and nobles from all parts of Europe flocked to his jousts and tournaments. See Harante's *Histoire des Ducs de Bourgogne de la Maison de Valois*.

**Philliphaugh**, on Yarrow Water, 3 miles WSW. of Selkirk, the property from 1461 till 1847 of the 'Murray' family, on which the 'Murray' bought the ballad. Here, on 13th September 1645, Montrose (q.v.) was defeated by David Leslie, who butchered more than a hundred Irish prisoners. See Craig Brown's *Selkirkshire* (1886).

**Philip Nerl**, St. See Now.

**Phillipville**, a seaport of Algeria, the harbour of Constantine, from which it lies 54 miles NNE. by rail. There is a magnificent harbour (1882) protected by two molea, one 4500 feet long, the other 1310 feet. The town is quite new, having been built since 1835 on the site of the ancient Roucauda. The imports and exports together reach £3,500,000 per annum. Pop. (1872) 10,267; (1891) 15,788.

**Philippi**, a city of Macedonia. It was named after Philip II. of Macedon (359-336 B.C.), who enlarged it because of the gold-mines in its neighbourhood. It is famous on account of the two battles fought in 42 B.C. between Antony and Octavius on the one side and the republicans under Brutus and Cassius on the other, in the second of which the republicans perished. The apostle Paul founded a Christian church here, to which one of his epistles is addressed.

**Philippians**, Epistle to the, the latest of the four letters that claim to have been written by the apostle Paul during his captivity (see **Paul**). The Philippian Church was looked upon with peculiar tenderness and affection by the apostle. It was one of the most fruitful of his churches, and remained, after some disasters, a flourishing church. The external evidence in favour of the genuineness of this epistle is exceptionally strong; it is added to by Polycarp, and enumerated among the Pauline writings both by Marcion and by the writer of the Muratorian canon. The arguments of Baur and others against its genuineness, which turn purely on questions of biblical theology, such as the compatibility of Phil. ii. 6-11 with 1 Cor. xv. 45-49, or of Phil. iii. 21 with the other expressions in these disputed writings, still find some supporters (one of the latest and ablest being Holsten); but they are not regarded as convincing even by Hilgenfeld, Schenk and Weizsäcker, Pfeiderer, and Harnack. There are commentaries on **Philippians** by Baur, F. Weisaetter, Condrinus (Philippien, 3d ed. 1865), Lightfoot (6th ed. 1881), and C. J. Vaughan (1882).

**Philippines**, originally the three orisons of Demosthenes against Philip of Macedon. The name was afterwards applied to Cicero's fourteen orations against the ambitions and dangerous designs of Mark Antony. It is now commonly employed to designate any severe and violent inexacte, whether oral or written.

**Philippine Islands**, a large insular group forming a northern section of the Eastern Archipelago, from which it is separated by the two profound abysses of the Salu (Mindoro) and Celebes Seas, 2000 to 4000 fathoms deep. But these seas are enclosed by the three insular chains of Palawan, with Balabac in the north, Suln in the centre, and Sangaui with Siau in the south, all of which lie in shallow waters, and form a geological connection between the Philippines and the Celebes. The southern, southeastern, and southwestern Philippines and Celebes in the south. The archipelago, which is washed on the east side by the Pacific Ocean (3000 fathoms) and in the north-west by the China Sea (2000 fathoms), lies in 4°-21° N. lat. and 117°-127° E. long., and comprises a vast aggregate of over 2000 islands.
NATIVES OF NUEVA ECÍJA PROVINCE, LUZON, PHILIPPINE ISLANDS.

A NATIVE HOUSE, SAN PALOC, LUZON, PHILIPPINE ISLANDS.

of all sizes, from mere rocks and reefs to the great lands of Luzon and Mindanao. The total area is about 114,300 sq. m.; the areas of the chief islands are about as follows: Luzon, 44,400 sq. m.; Mindanao, 34,000; Palawan (Paragua), 2515; and in the Visayan group, Mindoro, 3,700; Cebu, 2,000; Bohol, 1,617; and Masbate, 1,352. The population is variously estimated at from 7,500,000 to 9,500,000.

The archipelago is disposed nearly due north and south, and is essentially mountainous and volcanic, lying in the direct line of the vast igneous chain which sweeps round from Sumatra and Java through the Lesser Sunda groups and the Moluccas northwards to Formosa and Japan. In the Philippines the first link in this system going southwards is the volcanic islet of Baluyan on the north coast of Luzon; but beyond the remarkable active volcano of Taal (768 feet), near Manila Bay, the chain ramifies into an eastern and a western branch, which traverse the whole of the archipelago, and which are continued northwards by the sub-arc of Sulu and Sangir. The eastern branch develops the lofty cones of Mayon (9000 feet) and Bulusan at the south-eastern extremity of Luzon, while the western branch gives rise to those of Malapinon and Banahao in Negros and Camiguin. The two branches of Mindanao in this island the two branches converge at the head of the Gulf of Davao, where they culminate in Apo (10,400 feet), highest point in the Philippines. These various ranges, which cover nearly the whole surface of the archipelago, leaving room for scarcely any except except about the lower courses of the rivers, consist mainly of very old eruptive rocks, in many places covered by later tertiary, quaternary, and modern secoiria and lavas. The underground forces are still active, and reveal themselves by tremendous eruptions, such as those of Mayon in 1766 and of Davao in 1814, and especially by earthquakes, which are almost continuous, keeping the seismographs of the observatory at Manila in a constant state of vibration.

Manila itself was nearly destroyed by the earthquake of 1863, which was followed by the disastrous conflagration of 1856, and by the fires of 1852, 1870, and 1874, which spread over the whole city.

The navigation of the inland waters is endangered not only by these disturbances, but also by the conflicting currents caused by opposing tidal waves, and by the cyclones, here called typhoons, which range as far south as about 10° N. lat. (see Map at Asia).

Owing to the parallel disposition of the mountain-ranges, space is afforded for the development of several large rivers, such as the Cagayan (Rio Grande), which drains about one-fourth of Luzon, flowing for 229 miles northwards between the Sierra Madre and the North Cordillera east and west; the Agno and Pampanga on the west side of the same island; and in Mindanao the Agusan (Butuan), navigable by large vessels for over 60 miles, and the Rio Grande de Mindanao, which flows from Lake Mayon in the centre of the island first south-west then north-east to Illana Bay in the Celebes Sea. This river is joined by the emissaries of several other lakes, and a characteristic feature of the landscape in most of the islands is the lake-ground in and about the centres of which there are several other lakes, which send their overflow through short coast-streams to all the surrounding waters. The most important and best known of these emissaries in Luzon are the Pasipit, which drains Lake Bom- bong, and the Pasig, which flows from the Laguna de Victoria (Map, page 329); both are supposed to be flooded craters, while others are of marine origin, bays and inlets cut off from the sea by the erupive matter ejected from the neighbouring volcanoes in former geological epochs.

Thanks to the general elevation of the land, and the prevailing sea-breezes, the climate, although moist and hot, is less insalubrious than that of most tropical lands. The fevers are generally of a somewhat mild, intermittent type, and the most dreaded malady is leprosy, dysentery, and anemia; leprosy exists in Luzon, but its ravages are confined to small areas. As elsewhere in the Eastern Archipelago, there are two seasons, a wet and a dry, which are determined by the trade-winds, but with relations to the peculiar configuration of the land, may be said to go on simultaneously. Thus, for the southern and western slopes, the south-west monsoon is the wet, the north-east the dry season, the recurrence of these periods being reversed on the opposite slopes of the same ranges. At Manila, which is exposed to the south-west winds, the rains last from June to November, dry weather for the rest of the year; but this succession is elsewhere constantly modified, especially by the trend and altitude of the mountain-chains. On the other hand, the temperature varies little throughout the year, ranging from about 77° F. in December (the coldest month) to 86° F. in May (the hottest month), while the greatest extremes recorded at the Manila Observatory are not more than 40 degrees (80°—120°). But a great rainfall is the rule, and is caused by the monsoon winds blowing from 70 to 120 inches per annum at Manila, while in parts of Mindanao the average per annum is 142 inches.

The indigenous flora, which is nowhere surpassed in variety and exuberance, indicates a long connection of the Philippines with Indo-Malaysia, and more especially relations with Austro-Malaysia, as seen through Celebes. Thus all the local genera are represented in the Great Sunda Islands and Malay Peninsula, but only very few in the Australasian world; absolutely independent forms are extremely rare, and generally represented only by a single type. Vast spaces are still covered with magnificent prismatic forests containing a great number of dyewoods, fine, hard-grained, medicinal and other useful plants, such as ebony, sapan, tamarind, guingumita, the incorruptible magkono (a myrtaceous), buyan, coconut, pandanus, nipa, and many other tropical trees. The most useful are the fibrous plants, such as the gigantic bejoco, the buri, canegore, and alaca (Manilla hemp). On the plantations are grown several varieties of rice, maize, sugar-cane, cotton, coffee, the cacao, tobacco, and the tobacco of Cuba. Above 6000 feet the forest and alpine floras are almost exclusively Malayan, and nearly identical with those of Borneo and Sumatra.

The native fauna is remarkable for the total absence of many large mammals, such as the tiger, elephant, rhinoceros, bear, tapir, orang-outang, which nevertheless occur in the Sunda Islands. Hence the only dangerous animals are the crocodile, snakes, and some other reptiles. The largest wild mammal is the buffalo, and next to it the gibbon, besides which there are several other primates such as the thick-tailed tamarind, the pithecia, and the money-tailed tamarind. Above 6000 feet the forest and alpine floras are almost exclusively Malaysian, and nearly identical with those of Borneo and Sumatra.

The carnivores are chiefly represented by several species of civet, the insectivora by the porcupine, and bats and squirrels are rare; while the herbivora are few, and the gallinaceous family especially presents some remarkable forms, such as the labugro (Galura bonkicei) and the bullfesigay, noted for its size, courage, and beautiful plumage. An endless variety of birds is abundant, while the fresh and marine waters abound in fishes, turtles, molluscs (including both the pearl and mother-of-pearl oyster), sponges (euplectella and other exquisites varieties).

Of minerals the most widely diffused are coal
and iron; copper, gold, lead, sulphur, cinnabar, quicksilver, alun, Jasper, marble, and fine building stone are found. But the mineral resources are but little developed, and the most prominent among them are the islands of Negros, Mindanao, and several other islands. The intruding Indonesian and Malay peoples now form a considerable portion of the population. The Indonesians (see Malay), estimated at about 200,000, are divided into numerous tribes, confined to Mindaanao; they are mostly 'infeles' (i.e. pagans). The Malays are either 'Indies' (i.e. Roman Catholics) or 'Moros' (i.e. Mohammedans). The chief Islands are the Tagayas of Luzon, about 1,644,000 in number, and the Visayas (lilaysan), in the Visayas group and parts of Palawan and Mindanao, about 2,600,000. The Moros, numbering about 268,000, are chiefly in Palawan and Mindanao. The Malays have intermarried with the Chinese (of whom there are about 40,000 in the archipelago), Indonesians, Negritos; and Arabs, and to an extent with Spaniards and other Europeans. The Tagal and Visayan languages are the most highly developed of the Malayo-Polynesian family, of which they are gradually absorbing all the other dialects current in the archipelago.

Discovered in 1521 by Magellan, who was killed on the islet of Mactan on April 27 of that year, the Philippines were officially annexed to Spain in 1565, and until 1898 remained a part of the Spanish dominion. Spanish rule was oppressive, taxation monstrous, and the tyranny of the religious orders unrestrained, and risings repeatedly took place—as in 1872. The rebellion in 1896 went on until the Spanish-American War began in 1898. The first serious blow in the war was given in Manila harbour (May 1), when the Spanish fleet was totally destroyed by an American squadron under Commodore Dewey, and on August 13 the city capitulated to the American forces. As a result of the war the Philippines were ceded to the United States on a payment of $20,000,000 in November 1898. But the Tagal, under Emilio Aguinaldo, demanded complete independence, and early in September 1898 had formed a revolutionary government, with Malolos as the capital, Aguinaldo being elected president. Though relations continued strained through the remainder of 1898, hostilities did not commence until February 4, 1900. Fighting continued until 1901; but the decisive action was fought, as the Filipinos generally split up into small bands, which were defeated and routed, only to reappear at another time. American commissioners—Admiral Dewey, J. G. Schurman, Charles Denby, and Dean C. Worcester—were in the Philippines during a large part of 1899, collecting information for use in administering the islands, and endeavouring to place before the Filipinos the true view of American sovereignty, in which they were partially successful. Law courts have been opened in Manila, Philippines, andInstances presided over by Philippine citizens, and civil government has been established in places, notably in Negros in 1890. A second commission, charged with administering the islands, landed at Manila June 3, 1900.

The total value of exports in 1896 was $20,175,000, the imports being imported with a value of $8,600,000: abaca (or hemp), $7,500,000; copra, $1,575,000; tobacco, $2,500,000; and cigars, $750,000. The imports included rice, flour, coal, petroleum, &c., to a value of $19,631,250. Owing to the disturbed condition of the islands, commerce has been depressed during the last few years, but the official figures for the first seven months of 1900 placed the exports at $8,350,500; imports, $12,670,430. China and Great Britain ranked re-

spectively first and second in both imports and exports. Manila (q.v.), in Luzon, is the capital, and there are numerous other towns of considerable size. A railroad, 120 miles long, runs NNW. from Manila to Dagusan.

(vol. xxx. 1887); Montero y Vidal, El Archipel. Filip. (1886), and Historia General de Filip. (1887); and John Foreman, The Philippines and Independe¬

ces (1892).

Philippopolis, capital of Eastern Roumelia (or Southern Bulgaria), on the navigable Maritza, 110 miles by rail W. by N. of Adrianople. It manufactures silk, cotton, tobacco, leather, &c., and prepares and exports ottos of roses (to the value of $25,000). Pop. (1893) 65,023, of whom nearly half are Turks and Greeks, and others than Bulgarians. An outpost of the Macedonian kingdom, it was ruined by the Goths, captured by the Turks (1363), destroyed by an earthquake (1818), burned (1846), and occupied by the Russians (1878).

Philipsburg, a town of Baden on the Rhine's right bank, 16 miles N. of Carlsruhe. Fortified till 1800, it was often besieged. Pop. 4822.

Philips, Ambrose, minor poet, was descended from a Leicestershire family, and born about 1671. He was educated at St John's College, Cambridge, and contributed to the university memorial volumes on the death of Queen Mary. Coming up to Lon¬

don he became intimate with Addison and Steele, did lack work for Tonson, and first gained a reputation by the 'Winter-piece' in the Tatler (No. 12) and the six Pastoral which opened the sixth volume of Tonson's Miscellany (1700), of which the first four volumes had been edited by Dryden. Strangely enough the same volume closed with the Pastoral of the young Pope, whose jealousy was aroused by Tickell's praising Philips and passing over himself, in his paper in the Guardian on Pastoral Poetry from 1690 to 1700 (1703), in which he took a characteristic revenge by a paper in the Guardian (No. 40), in which the worst of the verses of Philips were ironically exalted above the best of his own. His design he disguised with such dexterity that, though Addison discovered it, as Dr Johnson tells us, Steele was deceived, and was afraid of displeasing Pope by publishing his paper. Philips is said to have hung up a rod in Hutton's Coffee-house with which he threatened to chastise Pope on the first occasion. Pope nourished his anger against him, and all the more after his own immortal Pastoral was published to whose circle Philips belonged, and did not forget him in the Dunciad. Philips supported the government in the columns of the Free-thinker, and was rewarded by being made secretary to Archbishop Boulter in Ireland. Later he sat for Armagh, acted as secretary to the Good Queen, and judge of the Supreme Court, and after his patron Boulter's death returned to London, and died in 1749. Of his plays, The Distressed Mother (1712)—an adaptation from Racine's Andromache—was warmly praised in the Spectator; The Briton and the Humphry, Duke of Gloucester last enjoyed during the few years of whose circle Philips belonged, and their Pastoral is vigorous and easy yet graceful verse, but lack the charm that belongs to Gay, whose Shepherd's Week was really written at Pope's
instigation to take Phillips off. Some of his odes, addressed to children, and written with infantine simplicity of diction, earned him from Henry Carey the lasting nickname of ‘Namby-Pamby.’

**Phylis or Phyllis, Edward**, the elder of the two nephews brought up and educated by Master Anne Lister’s widow, Susanna E. Phillips held a government office in Chancery, and died in 1631, leaving two sons to Milton’s care. Edward Phillips was born in 1630, and became a student of Magdalen College, Oxford, but left in 1631 without taking a degree. In 1660 he was tutor to the son of John Evelyn of Surrey, and then moved to Essex. He is mentioned in Evelyn’s Diary as ‘not at all infected by Milton’s principles,’ yet certainly he entertained a great respect and admiration for his uncle, and not only extolled Milton in his *Theatrwm Postharmm* as ‘the exactest of heroic poetaries, ’ who hath revived the majesty and true decorum of Heroic Poesy and Tragedy,’ but has left us a valuable though short and fragmentary Life of the poet. This was originally prefixed (1694) to a translation of Milton’s *Letters of State*, but was omitted in the edition of 1695 of *Phylis* and *J. Phillips* (1815, pp. 350–353), and is, as Johnson says, ‘the only authentic account of Milton’s domestic manners.’ Of his numerous works may be mentioned a complete edition (the first) of the *Poems of Drummond of Hawthornden* (1655); *New World of English Words* (1658); a kind of dictionary, which went through several editions; the *Continuation of Baker’s Chronicle of the Kings of England* (1655); *Theatrwm Postharmm*, or a Complete Collection of the Poets (1673); the *Tractatus de Curtum DHymnatico* (1661); *Theatrwm Postharmm* in the 18th edition of *Milton* (1700); the *Liber ab Heracleo Incertum de Lingua Latina* (1652). Milton, says Aubrey, made his nephews songsters, and sang from the time they were with him, and verses by both are found in *Ages and Dialogues for One, Two, and Three Voices*, by Henry Lawes (1663). Edward is supposed to have died shortly after the publication (1694) of the *Letters of State*.

**Phylis, John**, Milton’s younger nephew and more peculiar charge, born in 1631, was, like his brother Edward, educated by his uncle, and frequently acted as his amanuensis. It may be supposed that Milton had formed a high opinion of his literary capability, since he entrusted to John rather than to John the writing of the *Revelations of the Kingdom of Heaven* and *Apologia pro Rege et Populo Anglicana* (1652), himself correcting it with the utmost care. But if John was Edward’s superior in ability, he was greatly his inferior in character, and persistently displayed an unnatural animosity to his uncle and benefactor. His next work was *A Satyr against Hypocrisses* (1655), a bitter anti-Puritan poem and attack on Cromwell, written with considerable talent, but in a strain of coarse buffoonery. Somewhat in the style of Chaucer, he describes a Sunday in Cromwell’s time, a christening; and a Wednesday last with the extravagant supper at night. This production was frequently reprinted, and must have caused Milton no small disappointment and annoyance. In 1660 John amused himself and the world with his *Mantellion or the Prophetic Egyptian*; a book which, though written with great care, was however, extremely successful; he was also a most industrious translator, and in little more than a year (1677) published three large folio translations, *Almahide*, from the French of Madame de Senécdé, on which was founded Dryden’s tragedy, *The Conquest of Granada*, the *Calvary*; and *Tavernier’s Voyages*. Phillips (or Phillips) wrote many scurrilous pamphlets, and died in 1706.

**Phylis, John**, described on the monument in Westminster Abbey erected by Sir Simon Harcourt to his memory as a second Milton. He was the author of three very popular poems, *The Splendid Shilling*, a burlesque of Milton’s manner; *Cider*, an imitation of Virgil; and *Blenheim*, a Tory celebration of Marlborough’s great victory. He was born in 1676, but, curiously enough, was registered at Winchester as five years, and at Christ Church, Oxford, as six years younger than he really was. He died in 1708, and was buried in the cathedral at Hereford.

**Phylis, Katherine**, ‘the matchless Orinda,’ was born the daughter of a respected citizen of London, and a Puritan merchant, on New-year’s Day 1651. A precocious child, she early became strongly royalist in feeling, and in her seventeenth year she married a worthy Welsh gentleman, James Phillips of Cardigan Priory. Her earliest poem was an address to Henry Vaughan, Poet Laureate, in the appearance of his *Dioi Sceaus* (1651). About the same time she seems to have assumed her melodious non-de-plume of Orinda, having formed among her neighbours of either sex a Society of Friendship, the members of which must needs be re-baptised—the ladies as Virginius, Rosamund, Salvea, and the gentlemen as Palamon, Silvander, Antenor (her own husband), and Polarchus (Sir Charles Cotterel, her greatest friend, her forty-eight letters to whom were published in 1705). Orinda is our earliest sentimental writer, and she has tears at will for the marriages and the other sufferings of her women, which she represents as outrages on the sufficiency of friendship. Yet she was a worthy woman and good wife, despite her overstrained sentimentality, and deserved the honour of a dedication from Jeremy Taylor (Dialogue on the Nature, Offices, and Passions of Friendship) and from Sir John Carew in *D_ACTIV* (1662), and here Roger, Earl of Orrery, and the rest gave her a flattering reception. On a visit to London she caught smallpox, and died at thirty-three, June 22, 1684. At Dublin she translated Cornelle’s *Poetacria*, in the last year of the greatest part of his *Horace*. Her poems were surreptitiously printed at London in 1663, but an authoritative edition was issued in 1667. The matchless Orinda’s poetry has long since faded into forgetfulness, despite the chorus of contemporary jurors. From Cowley and even Pope not Keats found her poems in 1817 while writing *Endymion*, and in a letter to Reynolds speaks of them as showing ‘a most delicate fancy of the Fletcher kind.’ Mr Gosse conjectures the scarce volume of *Female Poems* (1679) written by Epiphelia to have been the work of Orinda’s only daughter, Joan (born about 1654), who married Mr Wogan of Pembroke, in 1679. See the admirable essay by Mr Edmund Gosse in *Eighteenth Century Studies* (2d ed. 1885).

**Phyliphon**, a market-town of King’s County, Ireland, 8 miles E. of Tullamore and 49 miles W. by S. of O. of Lough Allen, and takes its name from Queen Mary’s consort, Philip of Spain. *Pop. 829.*

**Philistines** (Heb. Polelatim; Gr. alollphoi, ‘strangers’), a people mentioned in the Bible as being in frequent contact with the Jews, and who lived on the coast of the Mediterranean, to the south-west of Judea, from Ekron towards the Ionian coast; in modern times they are divided into the tribes of Dan, Simeon, and Judah. Our information about the origin of the Philistines is extremely obscure. The genealogical table in Genesis (x. 14) counts them among the Egyptian colonies (the *Casalhum, out of whom came the Philistines*); but according to II Esdras, vi. 4, and I Maccabees, ii. 123, they came from Caphtor—formerly, from mere resemblance of the word, identified
with Cappadocia. Others have, groundlessly, derived them from the Pelasgians. Of late the tendency is to believe that the Phœnicians, who were undoubtedly immigrants, came from Crete, the collocation of Cheroheites (Cretans) and Peleleites (2 Sam. viii. and xiv.) favouring this view. But they seem to have become thoroughly Semiticised in speech, their language being undistinguishable from that of their Hittite neighbours. Their Baal-cult and Dagon (q.v.) are apparently Semitic.

It is doubtful if Aimebelech, king of Gerar (Gen. xxii., xxvi.), was king of this people or merely of the country afterwards Philistia; more probably the expulsions of the Philistines (Judg. xiii.) justly ascribed before the new invaders, marks their first appearance as aggressive enemies. They were subject to five princes, who ruled over the provinces of Gaza, Askelod, Askalon, Gath, and Ekron. They were so powerful at the time of Eli that they carried away the Ark. Samuel's rule was terminated by the battle of Mizpah. Saul was constantly engaged in warding off their new encroachments, and at Gilboa he and his sons fell in a disastrous battle against them. David succeeded in routing them repeatedly; and under Solomon their country seems to have been all but incorporated in the Jewish empire. The internal troubles of Judah emboldened the Philistines once more to open resistance; but Hezekiah subdued their country with the aid of the Egyptians. The Assyrians afterwards took Ashdod; and in the time of the Maccabees the Philistines were Syrian subjects; by the time of Herod the name of the country had long been lost in that of Palestine. A civilised, agricultural, commercial, and warlike nation, they traded largely, and their wares seem to have been much sought after.

See also the various histories of the Jezreelites cited at Jezra; Schrader's Keilschriftchronik (2d ed. 1853); Wright's Comp. Gram. of the Semitic Languages (1860).—German students call those who have ceased to be students, as well as non-students, tradesmen, &c., Philister or Philistines; hence the further term of 'Philistine,' 'narrow-minded,' in which application the term has come to be used in Britain, especially through Mr. Matthew Arnold's influence.

Philirofe. Sir Robert Joseph, born 5th November, 1795, and educated at Oxford, was, after serving in the Board of Control, had a brilliant career at the bar. He sat in parliament as a Whig from 1833 to 1857; and held in succession the offices of Advocate-general (1842, when he was knighted), Judge Advocate-general (1871), judge of the Arches Court (1867-75) and of the High Court of Admiralty (1867-83). Made a baronet in 1881, he died 4th February 1885. His most important works are his Commentaries upon International Law (4 vols. 1834-61; 3d ed. 1879), and his Ecclesiastical Law of the Church of England (2 vols. 1873-87).

Philly. John, R.A., was born, an old soldier's son, at Aberdeen on 19th April 1817. He was apprenticed to a painter and glazier, but in 1836 was sent by Lord Panmure to London, where he was ere long admitted to the schools of the Royal Academy. In 1839 he began to exhibit in the Academy Exhibition. Most of his early works were of Scotch character, such as a 'Scottish Fair,' and 'Baptism in Scotland.' In 1851 he went to Spain in search of health. On his return he became noted as a painter of the habits and emotions of the Spanish people, and was known as 'Spanish Phillips.' He is among the Gypsies at Seville.' His pictures for 1854-55, 'A Letter Writer of Seville' and 'El Paseo,' were purchased by the Queen. In 1857 he became A.R.A., in 1859 R.A. 'The Marriage of the Princec Royal' (1860) was a success, as was also the House of Commons, containing upwards of thirty portraits of the leading Tory set of both sides of the House. But his most triumphs were in Spanish subjects, such as 'La Gloria' (1864) and 'El Cigarillo' (1864). He twice again visited Spain, was in Italy in 1866, and died in London, 27th February 1867. His 'Early Career of Murillo' sold in 1865 to Mr. Guinness, who, as a political democrat, and his light effects were broad and strong.

Philips, See Philip, Halliwell-Philips.

Philips, Wendell, abolitionist, was born 20th November 1811, at Boston, Massachusetts, the son of the first mayor of the city (1822). He graduated at Harvard with Motley in 1831, studied law, and was called to the bar in 1834. Before clients came he had been drawn away from his profession to the real work of his life. A timely and important speech in Faneuil Hall in 1837 made him at once the principal orator of the anti-slavery party; and henceforth, until the president's proclamation of It January 1863, he was Garrison's loyal and valued ally, his lectures and addresses doing more for their cause than can well be estimated. He also championed the cause of temperance, and that of women, and advocated the rights of the Indians. In 1870 he was nominated for governor of the Prohibition party. He died 2d February 1884. His speeches and letters were collected in 1863 (new ed. 1884); and there is a Life by G. L. Austin (Boston, 1888).

Philipsburg, a town of New Jersey, on the Delaware River (crossed by two railroad bridges), opposite Easton, at the western terminus of the Morris Canal, and 85 miles south of New York by rail. It contains a rolling-mill and several foundries, boiler-and locomotive works, &c. Pop. (1900) 10,052.

Philoctetes, a famous archer, the friend and armour-bearer of Hercules, who bequeathed him his bow and poisoned arrows. As one of the suitors of Helen, he led seven ships against Troy; but, being bitten in the foot by a snake (or, according to one story, wounded by his own arrows), he fell ill. As his wound gave forth an undearable stench, the Greeks left him on the island of Lemnos, where for ten years he spent a miserable life. He could neither eat nor be taken without the arrows of Hercules, so Ulysses and Neoptolemus were despatched to bring Philoctetes to the Greek camp; where, healed by Asclepius or his sons, the restored hero slew Paris, and helped powerfully in the taking of Troy. After the war he settled in Italy. A play of Sophocles is named from him.

Philo Byblus. See PHILAE, p. 133.

Philolus, the Philosopher, was born at Alexandria, most probably about 20-10 B.C. Belonging to a wealthy family—his brother, according to Josephus, was the alabarch or archbishop Alexander—he received the most liberal education; and such was his zeal for learning that at a very early age he had passed through the ordinary course of Greek studies. Although every one of the different free sciences and arts included in the Enneadokles, he says, attracted him like so many beautiful flowers, he could not withdraw from the study of mathematics, the mistress of them all—Philosophy. Metaphysical investigation was the only thing which, he tells us, could give him anything like satisfaction or pleasure. He was intimately acquainted with Plato, the Greek tragedians, and Homer, and he was both an admirer and a critic of the Styes and the Pythagoreans. With these and especially with Plato his affinities are closest—an old proverb runs: Χρήστες ον Φιλόπολλος Φιλός Πλάτωνι. Yet with all his Greek culture he remained a Jew, holding Jewish philosophy as the highest wisdom.
the divine revelation given to Moses as the source of all true knowledge in religion. He had completely mastered the literature of his nation, but, strange to say, had never read any of the ancient Hebrew scholars. When over fifty years of age he went to Rome as the advocate of his Alexandrian brethren, who had refused to worship Caligula in obedience to the imperial edict. His De Legatione ad Gaium gives the best reason of the difference between the life we know little except what is recorded above, and that to which he once went to Jerusalem. His second mission to Rome, to the Emperor Claudius, on which occasion Eusebius reports that he made the acquaintance of the apostle Peter, is doubtful.

The record of the philosophical system of Philo, however, is most minutely known, and deserves the most careful study on account of the vast influence which it has exercised both on the Jewish and Christian world. To understand his system, it will be necessary to recall to memory the strange mental atmosphere of his day. The Alexandrians had endeavoured to make Judaism palatable to the refined Greeks, by proving it to be identical with the grandest conceptions of their philosophers and poets, and had quite allegorised away its distinctive characteristics. Philo was the first man who, although he was upon the other hand regarded as an allegorising tendency, made a bold and successful stand against a like evaporisation of the revealed religion of his fathers; which, indeed, in many cases had led people to throw off its yoke also outwardly. Himself a most zealous champion of Judaism, he himself says 'I endeavoured to instruct the most zealous of the philosophers who tried to defend their secret or overt apostasy by scoffing at the Law itself, who were 'impatient of their religious institutions, ever on the lookout for matter of censure and complaint against the Law of God, but more especially, for their own words, thoughtlessly urge all manner of objections.' He cannot understand how Jews, 'destined by divine authority to be the priests and prophets for all mankind,' could be found so utterly blind to the fact that that which is the position only of a few of the most sublime and excellent people, viz. the knowledge of the Highest—had by law and custom become the inheritance of every individual of their own people; whose real calling, in fact, it was to invoke the blessing of God on mankind, and who, when they offered up sacrifices 'for the people,' brought a sacrifice for the world. He has said that to Philo the divinity of the Jewish law is the basis and test of all true philosophy. Although, like his contemporaries, he holds that the greater part of the Pentateuch, both in its historical and legal portions, may be explained allegorically—nay, goes so far even as to call only the Ten Commandments, the fundamental rules of the Jewish theocracy, direct and immediate revelations, while the other parts of the Book are owing to Moses—he yet holds the latter to be the interpreter specially selected by God, to whose dicta in so far as also divine veneration and strict obedience are due and again, while admitting that many explanations of a metaphysical nature may be given to single passages, yet demands in general that their literal meaning shall not be tampered with. This literal meaning, in a sense to be understood is, the other explanations are mere speculation— exactly as the Midrash and some Church Fathers hold. At the same time it is true that without denying the literal meaning, again and again he permit the interpretation of the law, and is the more divinely, and indeed sometimes he treats the literal meaning as absurd. Only the allegorical method in his hands differed in so far from that of his contemporaries that to him these interpretations—for which he did not disdain sometimes even to use the numbers symbolically, or to derive Hebrew words from Greek roots, and the like—were not a mere play of fancy, in which he could exercise his powers of imagination, but, to a certain extent, a power that with the Deity. He has yet to speak, as combined with the Law. If the former could be shown, somehow or other, to be hinted at in the latter, then only he could be that which his all soul yearned to be—viz. the disciple of both: a Greek, with all the refinement of Greek culture, and a Jew—whom he endeavoured to prove that he even urged the necessity of allegory from the twofold reason of the anthropomorphism current in Scripture and from certain apparent superfluities, repetitions, and the like, which, in a record that emanated from the Deity, must needs have a special meaning of their own which required investigation and a peculiar interpretation. Yet this fanciful method never for one moment interfered with his real object of pointing out how Judaism most plainly and unmistakably was based upon the highest ethical principles.

His writings develop his ideas and his system in the two directions indicated. In that division of his writings principally which treats of the Creation (καταγεννησις) he allows allegory to take the reins out of his hands; in that on the Laws (φαιναμενα), he endeavours to prove that the Mosaic legislation is more and more, and clear, exulting the Mosaic legislation throughout at the expense of every other known to him. In a very few instances only is he induced to find fault, or to alter slightly, by way of allegory, the existing ordinances. His idea of the Law is intended to be in the highest degree philosophical, though its religious significance is never lost sight of. God alone is the real Good, the Perfect, the final cause of all things, which ceaselessly workflow from Himself. Of a second beginning is the primary light, which cannot be seen by itself, but which may be known from its rays that fill the whole world. Being infinite and uncreated, He is not to be compared with any created thing. He has, therefore, no name, and reveals Himself only in designations expressive of this 'inexpressibility,' such as 'the Place' (τος Μεχρικας Μακος), because He comprises all space, and there is nothing anywhere besides Him. He is better than Virtue and Knowledge, better than the Beautiful and the Good (αρετης και γηνις), simpler than the One, more palatable than the Many. He distinguishes no quality, or only negative ones. He is the existing Unity or Existence itself (ο εστος), comprising in the unpronounceable Tetragrammaton. As Creator, God manifests Himself to man, and in this phase of active revelation of God, which is as natural to Him as burning is to the heat, and cold to the snow, may be distinguished two distinct sides or essential properties, the Power and the Grace, to which correspond the two Scripture names of Elohim and Adonai. The Power also gives the laws and punishes the offender; while the Grace is the beneficent, forgiving, merciful quality. Yet, since there is not to be assumed an immediate influence of God upon the world, their respective natures being so different that a point of contact cannot be found, an intermediate class of beings had to be introduced, who could pass through whom He could act in and upon creation—viz. the spiritual world of ideas, which are not only 'Ideas,' or types, in the Platonic sense, but real, active powers (δυναμεις), surrounding God like a number of angels, who are ever ready to serve, who are the servants, who work His will, and by the Greeks are called good demons, by Moses angels. There are very many different degrees of perfection among them. Some are immediate 'serving angels;' others are the souls of the pious, of the prophets, and the people of Israel, who rise higher up to the Deity; others,
again, are the heads and chief representatives of the different nations, such as Israel does not need, since they properly belong to and acknowledge the Everlasting Heir of all Beings Himself. Collectively the Powers are used as equivalent to the nature or essence of God—his ideas or thoughts dominating and informing the universe; yet they are far from being substitutes for God. Zeller maintains that in Philo the universe and the heavens two real existences. Dr. Drummond refuses to admit that Philo imputed personality to the Powers, or that he identified them with the angels. Schürer maintains that we cannot deny definitely the personification of the Θεός or θεών, since Philo conceived of them both as independent hypostases and as immanent determinations of the Divine existence.

The Logos, or Divine Reason, comprises all these intermediate spiritual powers in his own essence. It is the universal idea, the one supreme and all-embracing thought, by which the universe is formed into a certain cosmos—a property of God, and the representative of God in his relation to the created world. As such the Logos is the highest of the angels, the "Beginning," the Name, the Word, the Primordial Angel, the first-born son of God, the second God (the antithesis of the first), the eternal Thought of God. As he expressed Thought of God it has a twofold aspect regarded as the οὐδέρε and the ἱνδος Logos, although this is not formally expressed by Philo. It becomes objective in the harmonies of the created world, and stands distinct from the same Thought when hidden in the silent depths of God, and known only to His omniscience. The Logos formed the world out of chaotic matter, regarded as a mass occupying space, and now considered as the μὴ λεγείν of Plato, again as the θέος of the Stoics. Man is a microcosm, a little Logos, in himself, a creation of the archetypal Logos, through whom he participates in the Deity, or, as Scripture has it, 'he is created in the image of God.' He stands between the higher and lower beings—in the middle of creation. The ethical hierarchy of Stoicism did not extend to the Logos. He is identical with the Mosaic ethics, in which the ideal is most exalted moral perfectibility or sanctity, and man's duties consist in veneration of God, and love and righteousness towards fellow-men. Philo holds firmly the belief in immortality. Eternity is the motionless duration of unalterable being; time but the moving succession of ever-shifting phenomena. Man is immortal by his heavenly nature; but as there are degrees in his divine nature, so there are degrees in his immortality, which only then deserves this name when it has been acquired by the supreme Logos. There is a vast difference between the mere living after death, which is common to all mankind, and the future existence of the perfect ones. Future recompense and punishment are not taken by him in the ordinary sense of the word. Virtue and sin both have their recompense at once; they are "in the soul," which is 'existing,' having finished its course in the sublunar world, carries this consciousness with it in a more intense and exalted manner. Paradise is Oeness with God; there is no hell with bodily punishments for souls without a body, and no heaven for the Stoic system (Christianity). Philo succeeded in proving against Dähne and others that matter, though eternal, is purely passive, and not itself necessarily evil in Philo's teaching. The source of the imperfection is not in the material as opposed to the spiritual, but in the phenomenal as opposed to the eternal. The human ζωή is seen as a school for the present life, and knowledge of that life is tantamount to the bondage of sense, and the loftiest principle of ethics is the utmost possible renunciation of sensuousness. The direct vision of God is possible only for those souls which have been lifted out of themselves and illumined by renunciation and reverence. The world is represented as the complete deliverance from the body beyond the gates of death, when the soul that has freed itself in life from the bondage of sense returns again to its original condition as pure spirit.

Philo's Messianic notions are vague in the extreme. He never even interprets certain scriptural passages alluding to some future Redeemer as referring to the soul. Yet he indicates his belief in a distant time when some hero will arise out of the midst of the nation who will gather all the dispersed together; and these, purified by long punishments, will henceforth form a happy, sinless, most prosperous community, to which all the other nations will be eager to belong. Still the Messianic hope is very obscure, and Dähne's identification of the Logos with the Messiah is indefensible.

We have only been able to indicate, in the slightest of outlines, the principal features of Philo's theology and philosophy, without endeavouring to follow any one of the manifold systematic schemes into which his scattered half-obscure dicta have here and there been pressed. His method of criticism and the main elements of his religious philosophy passed into the Christian church, and exercised a powerful influence over its thinkers. Nor can Philo ever lose his importance in the history of thought as the earliest eclectic religious philosopher, the clearest and best of that class of writers, in which were harmonised the rational and the irrational—the results of speculative thought with the suppositions of a supernatural revelation.

Philo's writings are numerous, and their arrangement presents no small difficulty to the student. Many of his writings are preserved in later compilations (H.E. ii. 18), but the bulk of these have been preserved in the Fathers and early Christian writers, like Eusebius, who quote Philo to an enormous extent. Many detached portions have been preserved in the apocryphal and apocryphal compilations of the earlier Christian Parallelists. The first and very imperfect edition of the Greek text was that published by Tümpelen (Paris, 1582), containing only sixty-three apocryphal works. The best of the Latin is that of Mangy (2 vols. folio, Lond. 1742), but a satisfactory collected edition is still a desideratum, neither that promised by Grossmann so long ago as 1829, nor that for which Tischendorf collected materials, ever having appeared. The Librius de Opificio mundi was edited by Leop. Cohn in 1889 as a specimen of a projected edition. Several writings of Philo preserved only in Armenian have been published in Latin translations by Jo. Bapt. Aurcher (Venice, 1822, 1826); and Greek portions of greater or less extent have been given by Mai, Grossmann, Tischendorf, Cardinal Pirra, and Professor J. Rembel Harris (Cambridge, 1886). The most complete and convenient series of the materials are contained in the hand edition of C. E. Richter (8 vols. Leip. 1828-30) and the Taurinum stereotype edition (8 vols. Leip. 1851-53). See the brief account of each book in Schürer's art. of Philo, Jews, People (2 vol. iv. iii. 1886) in Clark's translation. An important contribution to Philo bibliography is that by L. Masselief (Paris, 1888). There is an Eng. trans. by C. J. Yonge in Bolin's "Eccles. Library." (4 vols. 1854-55).

More than three-fourths of what has come down to us from Philo consists of three chief works on the Pentateuch: The Treasures or Hebrew Wisdom (in Armenian—a short explanation of Genesis and Exodus in question and answer; (2) Νόμων τῆς ἀλλαγούν, a large allegorical commentary on Genesis, in which the history is interpreted as a system of

brought with them the MSS. of Thucydides and of Plato, to be translated by Valla and by Ficinus; and it was in Italy that the first modern philologists laid the foundations of philology, which later became a large school at large by the great houses of the Manucci and the Giunta. But with the exception of Faerno Italy had no great scholar. Yet by its connection with France it produced scholars in northern Europe. Budé was secretary of Louis XII., whose main interests were in Italy; Lamblin visited Rome and Venice before he became the editor of Horace, of Lucretius, and of Cicero; while Muret, though born near Limoges, lived and worked at Rome from 1559 to his death in 1585, and at Rome he lodged for two years the year before his death. Later, during the decline of Italian learning, foremost of European scholars. Italian by descent, but born in France, where he edited his Manuils and wrote his De Emendatione Temporum, the first great work in historical criticism, he was led by his conversion to Protestantism eventually to retire from France to Leyden, where he ended his days, the dictator of the world of letters. Isaac Casaubon, a leader in exegesis, as Scaliger was in criticism, though born at Geneva, was the son of a French Huguenot refugee, and in France he lived during the most part of his life, till like Scaliger he fled south-west into the rising Protestantism of England. Justus Lipsius, the third great scholar of the day, was a Belgian, professor successively at Jena, at Leyden, and at Louvain; he also had travelled in Italy.

Of the members of the older German school the most famous is Erasmus, by birth a Hollander, but the centre of a band of able scholars at Basel, where he spent the last sixteen years of his life, well known in England, and for a short time a professor at Cambridge, a man of vast learning, but not a master in criticism, "the man of letters, the first who had appeared in Europe since the fall of the Roman empire" (Mark Pattison). He lived some three years in Italy, but gained, as he thought, nothing from it. Able scholars were Camerarius, professor at Leipsig, and Grotius of Antwerp, the first great lexicographer of Greek and Latin inscriptions.

For different reasons France and Germany ceased to be the nurseries of scholarship in the 17th century. The reign of Louis XIV. fostered modern rather than ancient literature; and Germany was the scene of furious war. But Scaliger’s influence lived on in Holland, at Leyden, where he died in 1649; Daniel Heinsius and his son Nicolas, Gronow, conspicuous for his skill in appreciating MSS. and Cluver, the first great writer on geography. At the same time Graeae was editing Cicero at Utrecht. Somewhat later in England lived the first of English scholars, Richard Bentley, in frequent correspondence with Dutch scholars, but owing nothing to them, a man whose astounding critical power could not always save him from errors due to his self-confidence. The only other Englishman whose name, like Bentley’s, has steadily grown with time was John Selden, professor of Greek at Cambridge at the end of the 18th century. Distinguished names in the school of Holland in the 18th century are Hemsterhuis and his pupils Ruhnken and Vaelckenae. In Germany we find Ernesti at Leipsig, the editor of Cicero; his scholar, Heyne, the founder of the school of Gottingen; Griesbach, professor of Greek at Cambridge, who was not only in Greek and Latin, but also in Arabic, whose edition of the Greek orators is still in use; Winckelmann, the first great writer on ancient art; Wolf, professor at Halle, best known as the great Homer critic, but whose general power and method almost entitled him to a place in the school of Scaliger and Bentley. Scholars of a later date, whose lives extended far into the 19th century, are Immanuel Bekker, professor at Berlin, editor of Plato, Thucydides, the orators, and Aristophanes; Godfrey Hermann, a scholar of unusual breadth, whose fame rests securely upon his work on Æschylus; Welecker, an outstanding professor of Sanskrit, who only late suffered the loss of H. A. J. Munro of Cambridge, the inquirer of Lachmann’s labour on Lucretius; of Madvig the Dane, a Latin scholar of eminent acuteness; and of Cobet, in whom the critical power of Holland seemed to be renewed again. (An excellent sketch of the last of these men is given in the Süddeutsche Zeitung, March 23, 1864, by Dr. Ulrichs of Würzburg, will be found in the first volume of Iwan Müller’s Handbuch der Klassischen Altertumswissenschaft.)

Speculations on the connection of Greek and Latin—e.g. that Latin was derived from some Greek dialect, and that both, as well as all the other languages of the earth, must be derived from Hebrew—are not wanting in the writings of the older scholars. It was reserved for an Englishman, Sir William Jones, in 1786, to point out that Sanskrit, Zend, Greek, Latin, Gothic, and Celtic belong to the same family; and that the later learned about 1770, born at Mainz in 1791, to become the founder of the special science of comparative philology. In his ‘conjugation-system,’ published at Frankfurt in 1816, he worked out the details of the principle already established by tracing out the history of the verb-forms of the Greek, Latin, Sanskrit, Germanic, and Teutonic as compared with Sanskrit. His monumental work, the Comparative Grammar, appeared at different times between 1833 and 1852. In this he lays down the phonetic laws of the several languages, and traces their grammatical forms back to their common origin in a last Indo-Germanic speech. It is impossible here to describe the development of this work in the hands of the singularly able men who laboured at it in the same generation, such as Jakob Grimm, the founder of the scientific study of the Teutonic languages; Pott, the most learned and voluminous of writers; Benfey, the acute philologist and accomplished Sanskritist. The most successful application of the science to Greek was made somewhat later by Georg Curtius, and to Latin by Corssen, and in France by Michel Breal. The common principle of all these writers was that the newer-changing change in every language is regulated by law; that in each language there is a regular sequence of sound, one passing into the other, not by chance or by the will of any speaker or speakers, but in a definite ascertainable course; and that only by the knowledge of these sequences, commonly but not very wisely termed ‘laws,’ can the science of language exist.

One of the best known of these is the sound-change commonly called ‘Grimm’s Law,’ which states the fact that whenever we find a k, t, or p in Sanskrit, Greek, or Gothic, we get a q, g, or b in English; parent-language, we shall find in English and most other Teutonic languages an h, th, etc.—e.g. sapd-ia (Lat. ‘cord.’) will appear as heart, ‘tres’ as ‘three’, ‘pes’ as ‘foot’; that y, d, b will appear as k, t, p (‘genus’ as ‘kin’, ‘uno’ as ‘two’); and aspirates (sh, dh, dhi, etc.) will be eliminated. ‘Ghans’ = ‘goose’, ‘blaugos’ = ‘beech’.

Further, that a subsequent ‘shifting’ of the same kind, but much less complete, took place many centuries later in Germany itself, and produced there the changes which distinguished the dialects of South Germany (‘High German’) from those of North Germany (‘Low German’), as it is called in Germany itself, ‘Platt-Deutsch’) and from our own English—e.g. ’drei’ from ‘three’, ’zwei’ from ‘two’, &c. Such astounding uniformity of change over so large an area was well calculated
to confirm the belief in the 'reign of law' in language. But that belief was extremely strengthened when in 1852 Karl Verner wrote a paper (published in Kuhn's "Zeitschrift", vol. xxii.), in which he showed that some apparent exceptions to Grimm's Law were really due to the operation of another and wider law (commonly called by his name) dating from very early times. This law, which he called the Teutonic, was derived from the parent-speech; in consequence of which at the present day a west Cumberland dalesman says 'fadder' and 'mudder,' but 'brother,' because in the parent-language (as attested by Sanskrit and Greek) the stress was laid on the last syllable in these words. But, from a reality it tear A here, for, in the Teutonic, though 'father,' in the Indo-German, to which we are common to both was accentuated in the first word, but not in the second; so also 'mind,' but 'growth,' (suffix of 'flood,' but 'death' (suffix -d). Here the regularity seems little less than miraculous; and it was discoveries such as this which led about this time to the rise of what is sometimes called the 'new science of philology,' not merely added to their utmost the principles of their predecessors. For example, Curtius and Schleicher held that the operation of unvarying law in certain cases did not exclude the possibility of 'sporadic changes' —i.e. of changes found in some words only, not in corresponding ones. But Schleicher recognized, thus, 'laerim' in Latin shows an i at the d of the original word, as proved by Greek δαίμων and our 'tair'; but they did not therefore think it necessary that every d should pass into l in Latin. The 'new school'—Leskien, Brugmann, Osthoff, Paul—to mention a few only of the most conspicuous members—held that sound-change so far as it is due to physical causes is absolutely uniform in any one language or dialect at the same time; and that the new form produced by such change in every case drives out the old one. Briefly put, phonetic law is inviolate, and it is no small thing as sporadic change—change attacking a few words, and sparing others; throughout the whole speech-area all words in which a particular sound occurs are alike affected. This doctrine has commanded very general assent; it is tempting to the scientific mind, and its strength lies in the number of apparent exceptions which have been satisfactorily explained. Yet the a priori arguments against it are strong, and it is certain that it is incapable of absolute proof: you cannot prove a negative. But the illustration of its supporters everywhere in the history of philology has been immense. They protested, and rightly, against the habit, seen in the later writings of Curtius and other less men in other languages, of allowing obvious exceptions to ascertained phonetic law on the ground of identity of function. Be the principle of the new men right or wrong, its observance in practice is excellent. But this protest is only one of the services of the new school. They (especially Paul) have called attention to the inner side of language: the older writers had spent themselves on the outer side, and its strength lies in the number of new products. The sounds which make language are due to the physical apparatus of speech. As such their nature can be exactly ascertained, and they are subject to changes which can be known and registered like the phenomena of any physical science (see Phonetics), and may be derived from the outer side of language. The inner development is due to the mind of man; and this, like all the other works of man, belongs to historical and not to physical science. Here the ruling principle is imitation. Every child learns every word it utters through imitation, and imitation of words heard from others or previously uttered by ourselves is the parent-speech of every grown-up man. That we are wholly unconscious of the process does not make the fact any less certain. One form of imitation especially active in speech is what grammarians call 'form-association.' Different forms of speech—e.g. preterite tenses of many verbs, or a particular way of expressing a meaning in their grammatical function, and tend to be thought of, and to be used, together. But these forms are nevertheless often very unlike; though their use may be the same they may have different origins—e.g. 'I swam,' 'I stood,' in English owe their distinctive variation to quite different causes, due to the adding of a suffix. Now, the mind is constantly acting under the influence of analogy to reduce such variations, to do away with unnecessary differences, to reduce old forms to one level, or to make new forms on the analogy of old ones. Thus, as under article GRAMMAR, we may say we 'run' and not 'we run' as our forefathers did, because the reason for the different vocalism of singular and plural is no longer discernible, and the unmeaning difference is 'levelled.' Again, we say 'I climbed,' not 'I clomb' any more because the preterite in ed is the old form, and common agreement condemns the tense, capable of being applied without difficulty when a new verb becomes necessary—e.g. we boycotted him. This principle of analogy (as for brevity it is often called) acts widely in every language; it is the law of the mind, and it must have acted much more upon vernaculars which had no literature (a good example may be seen in the reconstruction of the old Latin verb in modern Italian), and still more upon wholly unwritten languages. There are distinctive chief factors which act on language: one, the vis inerrar, which is the prime cause of phonetic change, and is in the main destructive, doing away with sounds or combinations of sounds which, owing to causes varying with nations and even with individuals, are inconvenient to produce; the other, the innate habit of man, which may destroy old forms, but is in the main reparative, giving new forms for those which through phonetic change had become obscure, and constantly producing new forms on the analogy of old ones to supply what wants in the aggregate of the human mind. For except in very rare cases man turns old speech-materials to new uses. He does not invent absolutely new names for new things as they become known to him or are produced by him. A hippocotomus was called a river-horse; nouns constantly springing up, being commonly either more picturesque or giving some
new circumstance. To murder is old, but to 'murk,' a verb coined from a once famous murderer, gives the added sense of smothering and hushing up; and the word seems likely to survive, though with its origin forgotten. To 'boyect,' express oneself in an abusive manner, is a new descriptive, and as yet its history is remembered.

This slight sketch may suffice to throw some light on the nature of language. It is a work of man, the product of man's mind and vocal organs, just as a statue or a picture is the product of his mind and hands. But it is different from these in some important respects. First, it is not a finished product, permanent and unchangeable. It is subject to incessant change, involuntary on its physical side, partly voluntary on the mental side. It is a constant threefold 'homing,' not a 'being,' as Plato might have put it; this change is obscure for literary languages; it becomes clear at once to any one who will take the pains of looking at the development of English from Chaucer's day to ours. Old forms die out, and new ones take their place (see PERS.), and Old English cases to be used: new ones take their place or are produced under new needs—e.g. the Boycott family—boyocott, boyocett, boyocett (extinct by this time), &c., all formed on the analogy of the words of other older families. A second recognition is that language is not an end in itself as a picture is: it exists for an end, communication between man and man. So long as this is achieved the form which language takes is immaterial: it may change so long as it is intelligible.

No doubt language once existent can serve other ends more or less connected with the first; but that communication was the first is undeniable.

But language is not the only means by which communication can be made. Animals, which have no language, certainly communicate. Man can communicate by gestures, by pictures—whether rude scratchings made on the ground, with a stick or the more polished drawings which developed into Egyptian hieroglyphics—or, lastly, by cries common to man and to beasts, the natural expressions of joy, fear, pain, &c. But such cries are not even the elements of language till they are connected to expressions of the mind, when the stimulating cause may be absent. Language itself arises when two men connect the same feeling with the same expression of it, and so can communicate that to others. There is no reason to believe that any brute has ever attained even to the last two steps. Their progress is arrested. A dog may bark to express delight, or to have a door opened to him, but he does no more than any dog could do 2000 years ago. Man can develop. It is not permissible, however, to lay down that the possession of speech is the barrier between man and the brute, and to settle thereby the question of the origin of man. Speech may be the clear differentia now. But it is at least conceivable that there may have been lost types between man and the common progenitor of man and the anthropoid ape with intermediate stages of speech-development. It is another matter to maintain that such development could have been produced by natural selection alone (see Wallace, Darvinism, p. 461, &c.).

The different languages of the world can be classified in their principal formation; and within the classes so reached different families of languages may be distinguished in which a common origin can be proved for the different languages of each family. Only the briefest sketch can be attempted here. We find two main families of these language signs (or hardly any signs) of indication (see Grammar) — e.g. in which the plural of 'man' is expressed not by vowel-change (as our 'men') nor by an added suffix (as in Latin 'lumnus-er') which has no independent value, but by such a combination as our 'man-kind,' where each part can be used independently. Such languages are the Chinese, the Himalayan, and the neighbouring states; they are commonly called Isolating. I1. Those which possess some degree of inflection—i.e. elements which have lost their independent meaning, and are mere grammatical machinery to make nouns, as fer in 'pa-ter,' or cases of nouns, as 'fadder—of groups of verbs, as s or th in 'gives' or 'giveth.' Such elements, however, are only the worn-out remnants of words compounded with other words (see Grammar); and the languages of this type may vary very much according to the degree of obscuration in the character of the compound. Some, like the Mongolian, the Finnish, the Hungarian, the Turkish, make very long compounds, yet the original elements, though not all capable of separate use, remain quite distinct and recognisable. Each language needs to be called 'agglutinative,' as different from the purely inflectional Sanskrit, Latin, &c.; but even these show signs of the phonetic change which produced inflections. The North American languages incorporate different elements which are each barely recognisable in the compound; the principle of composition is really different. The Aryan family of languages in South India—Tamil, Telugu, &c.—is also of the agglutinative sort. The languages of the purely inflectional type—i.e. those where the different elements of the original compound are so firmly welded together as to be frequently indistinguishable—are (1) the Semitic family, comprising Hebrew and the closely-connected Phoenician; Aramaic, spoken in Mesopotamia, Syria, and in later days in Palestine; Arabic; and some Abyssinian languages. This family is remarkable because its language shows the relation of the several ideas by three unchanging consonants, the relation of the various derived forms of the same idea being expressed by vowel-change. (11.) The Indo-Germanic or Aryan family. The first term is most likely to survive; it denotes the extreme of inflection. The languages spread—from Sanskrit Indic to Germanic (or Teutonic) Iceland. The term Aryan has not been adopted much outside of India. The chief languages of this family are (1) Sanskrit, of which the oldest remains are the Vedic hymns, with the compound Old Persian, which is much more ancient; (2) Armenian, as yet imperfectly known, with records dating from the 5th century A.D. (3) Greek, with its numerous dialects. (4) Albanian, proving to belong to this family by Bopp, and lately investigated by G. Meyer and others, but possessing no ancient records. (5) Italic, including Latin, and the Umbrian and Ocean dialects: from these are descended the modern (so-called) Romance languages—the Italian, Spanish, Portuguese, French, Wallachian, and the speech of certain Alpine districts (Grisons, &c.). (6) Celtic, including the ancient speech of Gaul, with its surviving remnants, the Bas Breton; the now extinct Cornish; the Welsh, still likely to survive; the Erse of Ireland; the Gaelic of the Highlands of Scotland (the records of these three date from about the 8th century); and the Manx. (7) The Teutonic, now more advanced. The ancient speech of Gothic, into which Ulfils translated the Gospels in the 4th century A.D.; the Scandinavian, of which a very old form is isolated in Iceland, more modern forms in Norway, Denmark, Sweden; the Anglo-Saxon; the Old Frisian; the Old Saxen of the 'Helland,' the parent of the Platt-Dentish languages of North Germany;
the Lower Franconian, whence comes the Dutch; the Franconian of Mid Germany; and the Old High German, spoken in different dialects from South to East of Central Europe, Asia and making modern literary German. (8) The Slavonic, to which belong Bohemian, Polish, Old Bulgarian, and the parents of the Russian and numerous dialects of south-eastern Europe; together with the Lithuanian, Old Prussian, and Lettsish languages of the same Baltic, while their identity have yet preserved strikingly early linguistic features. See Aryan Languages.

That there was such a language as the hypothetical parent of all these Aryan languages is certain (though such knowledge brings us no nearer to the one original language than if one there was—spoken by a Primeval Man). We can recover its character with certainty, for we know its suffixes both formative and inflectional; its vocabulary we know in part only. Now, if there was a language there must have been a people to speak that language—no doubt with many dialects, whence eventually sprang the derived languages which we know, and probably many others which are lost. Dialectal variation is the inevitable condition of all languages where there is no common literary tongue: the habit of the speech of a nation, and where there is great facility of communication throughout the area the dialects may die out, as they are rapidly doing in England. But though we assert with confidence that there was a common Indo-Germanic language, spoken by an Indo-Germanic people, we do not maintain that this people who speak the several languages derived from that the common parent are wholly of the same race, England, as we know, is inhabited by the descendants of Celts, of various nationalities enrolled in the Roman legions, of Angles, Saxons, Jutes, Frisians, of the oriento-Normans, and others whose language we speak the same English language. But that fact does not make us doubt that there was once a common Tentinonc language spoken (in various dialects) by the different members of a Tentinonc race which occupied Britain. It is extremely probable that there has been a like history in other lands where other Indo-Germanic languages are now spoken. That does not in the least disprove the existence of an Indo-Germanic race, speaking different Indo-Germanic dialects, settling themselves in the different countries, at the North of the modern territories of their blood with that of the races whom they found already there. The proportion of Indo-Germanic blood in any given nation may be considerable: it may be very little. It is possible that in some nations it may be nothing at all; some stronger, but less civilised race may have overpowered the Indo-Germanic stock, but taken their language. Such loss has its parallels in history—e.g. when the Norsemen conquered part of France, but lost their own language. This would explain the fact that races of marked racial differences, such as the Skulks and the Mandchus, are found speaking cognate languages with men of long skulls, ruddy colour, and light hair. Such an inconsistency has seemed to some anthropologists to absolutely destroy the value of language as a test of race. It does show that the Teutonic race as such are as valuable as anthropological ones; but neither give conclusive proof, only indications. The two sciences should work independently. Good anthropologists, such as Pöschle and Penka, may be bad linguists; but results drawn from harmony of the strongest evidence on either side may be fruitful. Most, however, of these problems will probably never admit of certain solution. The evidence which now would place the habitat of the parent-race in northern Europe is only somewhat more weighty than that which formerly placed it in Pamir.

See especially Paul's Principiën der Sprachgeschichte, translated by Strong (1888); and the History of Language (based on the same book), by Strong, Logeman, and Wheeler (1891). For Pischeking's Lehrbuch der Linguistik (Int. Sc. Series), Max-Müller's Essays on the Science of Language, and Sayce's Introduction to the Science of Language are the latter contains a full list of authorities. By far the best book on the Indo-Germanic languages in their earlier stage is Brugmann's Comparative Grammar (trans. vol. i. by Wright, vol. ii. by Connolly and Rousse, 1888). Here will be found mentioned all the recent works of any importance in this department. A short book referring chiefly to Greek and Latin is Victor Henry's Préci's de Grammaire Comparée (1889), also translated. For Romance languages the latest and most complete work is Griesbach's Grundriß der Romanischen Philologie (Strasburg, 1886—88), in which the different Romance languages are treated by the most competent authorities. Diez's Grammatik der Romanischen Sprachen, though somewhat out of date, is clear and good. A similar book on the German languages is Paul's Grundriß der Germanischen Philologie (1889 et seq.). Special students of English should use Sievers-Cook's Grammar of Old English (Ginn, Heath & Co, 1889). See Sweet's History of English Sounds (1888), and Skeat's Principles of English Etymology (1887 and 1891). For Phonetics, Sweet's Handbook of Phonetics should be consulted. All questions on the origin of the Germanic language and of its derivatives are exhaustively treated in the Prehistoric Antiquities of the Aryan Peoples (Schinz-Weisse, 1890). Isaac Taylor's Origin of the German Race (1817) was useful before this subject. The grammars and other works dealing with the modern languages of Europe are too numerous to be mentioned here.

Philomela, according to the Greek legend, was changed into either a swallow or a nightingale. Poets are (or rather were) fond of calling the nightingale by its classical name.

Philopomen, a patrician of Greece, was born at Megapolis about 225 B.C. In 222 he was one of the defenders of Megapolis against Cleomenes, king of Sparta, and next year he fought with the Macedonians against the Spartans. He then served in Crete with such distinction that in 210 he was appointed general of the Aegean horse. In 208 he was elected to the highest military dignity in Greece, being elected strategos or commander-in-chief of the Aegean League. The battle of Mantinea (208), in which the Spartans were again utterly routed, raised him to the pinnacle of fame, as well as of wealth, which he used to benefit his proclaimed liberator of Greece. So great was his influence that the Macedonian monarch, Philip, began to fear that Greece would regain its independence, and tried, vainly, to have him secretly assassinated. During the next few years he was absent in Crete, and returned to the Peloponnesus in 194 to find the Romans in Greece. On the departure of the consul Flaminius, Nabis of Sparta recommenced hostilities against the Achaeans; Philopomen was once more appointed strategos (192), and by his Persuasion nearly converted the league of Nabis. He now exerted all his power to heal the divisions among the Achaeans, and to prevent them from amusing the Romans a pretext for taking away their independence. In 188 he took a fierce revenge on Sparta where he had put a number of his friends to death, and was in consequence strongly censured by the Roman senate, and by Q. Cecilius Metellus, who was sent out as a commissioner to Greece in 183. Two years later Philopomen (now an old man of seventy) was elected strategos for the eighth time. When lying ill of a fever at Argos he rose from his sick-bed to quell the revolt of the Messenians, but was overpowered by numbers, and fell into the hands of Deinocrates, the leader of the Messenians, who two nights after sent him a cup of poison. Philopomen drank it and died.
Philosopher's Stone. See Alchemy.

Philosophy. In a subject where opinion has been and is still so much divided, as is the case in philosophy, it would be vain to attempt to formulate a definition which would be accepted by everyone. The objects of the science, its methods, may its unity or harmony in our conception of the universe, is the only safe guide in such a case; and by its aid we are happily able to fix upon the main elements that were present to the minds of the Greek thinkers who first consciously used the term with a sense of unity or harmony in our conception of the universe, and the definitions of all attempts at definition are to be found in Plato and Aristotle, and as these two philosophers dominated the human intellect for two thousand years, the ideas which they expressed on the subject inevitably shaped the conception of philosophy current during that time. In virtue of its long lease of life, this conception has established itself in the associations of language, and is vaguely present to the man of ordinary culture when he uses the term. It may claim, therefore, to be the historical sense of the term—the sense, that is to say, which it bore at any time, which it bears now out as that which has persistently asserted itself during more than two millennia of human progress. Pronounced deviations from the accepted usage occur mainly in connection with a sceptical or quasi-sceptical theory of knowledge, and will be dealt with later.

Tradition assigns the first employment of the word to Pythagoras, and makes him use it to signify merely the disinterested pursuit of knowledge. Socrates plays upon the etymology of the word, and contrasted the modesty, the truth-seeker, with the haughty, the self-seeking, the self-asserting, of the sophists. But, so far, the nature of the truth or knowledge which the philosopher seeks is not specified; the term is still vague and general. In fact, no kind of knowledge was at first alien to the philosopher. Philosophy has been truly called 'the mother of the sciences,' and it was only by slow degrees that the separate sciences attained an independent life. As specialization proceeded, however, philosophy could no longer in a literal sense 'take all knowledge to be her province;' the definitions of its domain after another of existence were surrendered to the scientific specialist. But the claim of philosophy to be the necessary complement of the special sciences—the only science of existence or of the universe as a whole—was not thereby surrendered. The specialist, so far as he is a true specialist, is like the man who cannot see the wood for the trees; he loses sight of the proportions of the whole in the details of his own province. The co-ordination of the sciences, the unification of knowledge, is a task which remains to be undertaken by the philosopher. Unity or harmony in our conception of the universe is the aim which philosophy always has in view. Whether this aim is attainable by man or not is a further question; but the idea of a system of things satisfactory to the reason and the moral sense remains the inextinguishable spring of philosophy. The philosopher, therefore, always has his eye upon the Whole; his true function is to correct the abstractions of the special sciences. Each science makes, and must make, its own working postulates or presuppositions, and the specialist is in error to make the working postulates of his own science (a mere portion of existence) as such. But philosophy has to review all these scientific postulates, and if possible to harmonize their conflicting claims by showing the relative and limited validity which belongs to each. Philosophy is in this connection the critic of the sciences—of the postulates which they make and the conceptions which they use; and she exercises this critical office in the interest of the Whole.

Something like this was present to Plato's mind when he described the philosopher as dunamis, a man who insists on seeing things together, who refuses to consider the parts out of their relation to the whole. It was a great advance, and therefore the inexorable foc of crude and premature generalisations from this or the other department of investigation which happens for the time to be most in evidence.

In Philosophy, however, already established a second account of philosophy, which, though unquestionably true in itself, has led, in the opinion of the present writer, to many questionable developments. The philosophers, says Plato, 'are those who are able to grasp the eternal and immutable,' 'those who set their affections on that which in each case really exists.' The philosopher, as the man who apprehends and follows after the essence or reality of things, is thus opposed to the man who dwells in appearances and the shows of sense. This distinction may be said to be implied in the demand for an explanation at all, and is present in Greek philosophy from the time of Pythagoras. Substance or unitary reality underlying all the diversity of the world around us? So ran the question which the early Greek thinkers asked themselves; and the explicit opposition between the world as it appears to the case and the world as reason recognizes it to be had already appeared (otherwise diametrically opposed) in Parmenides and Heraclitus. In the Platonist doctrine of transcendent Ideas the opposition receives a questionable expression; it appears more legitimately in the Aristotle doctrine of Substane and Cause. The philosopher, indeed, may set his face against the world and ask himself, What is the essence, the ultimate reality of things? who or what is the Being that is manufactured in 'all thinking things, all objects of all thought'? In this sense philosophy is still definable, in Aristotle's phrase, as Ontology, the science of being as being.

To very many, however, in modern times the search for this ultimate reality seems a hopeless quest, and philosophy therefore, in the form of metaphysics or ontology, is condemned by them as a mere postulate, a speculation. But under the influence of scientific habits of thought, it is now happily recovering. The Empiricism which bases itself on Hume, the Positivism which founds on Comte, and various phases of Kantian thought agree in this repudiation of metaphysics. The distinction between phenomena and noumena, which has been revived in a somewhat different form, and has become current in popular thought. Sensible objects and their laws may be known, it is argued, because in such an investigation we are not carried beyond the facts of present and possible experience; and these phenomena. But if we refuse to take this sensuous phantasmaporia simply as it stands—if we insist on referring it to some ultimate ground of existence as an explanation of why and how there is a phenomenal world at all—the object of our search is variously said to be nonmetal, metaphysical, metempirical, or transcendental, and to be unattainable by human reason. To those who hold this view philosophy becomes convertible with Epistemology or Theory of Knowledge (Erkenntniss-theorie). It becomes an inquiry into the human understanding, or a 'criticism' of the human understanding, by way of fixing the limits of our necessary ignorance, and thus justifying the negative position assumed towards metaphysics. To Hume and Comte, and to Kant himself in some of his moods, philosophy is thus a preventive against itself, or at least against what has ordinarily
Psychology, may be said to have established its
claim to be an independent science of observation
and experiment. Thus it may fall more
and more into the hands of specialists, it will always
remain connected with philosophy, seeing that the
knowing mind is the object which the psychologist
investigates. Similarly, Ethics is often treated as
the science of moral reality or of the moral sense,
but so conceived it really forms a part of scientific psychology. The strictly
philosophical part of Ethics is the theory of
obligation, and this is sometimes spoken of as the
Metaphysic of Ethics. The meaning assigned to
that designation given to it by Aristotle
necessity profoundly influence the general concep-
tion we may form of the universe. So, again,
Aesthetics may be treated as a department of
physiological psychology, as has mostly been the
case in England; but by many continental writers
the Philosophy of Art or the Philosophy of
the Beautiful has been intimately connected with
metaphysics. Jurisprudence on its philosophical
side is closely connected with Ethics, and is some-
times spoken of as the Philosophy of Law. The
Philosophy of History and the Philosophy of Rel-
igion exist only in theory; but the moral and
dead facts of history and in the different religions of
man the evolution of an idea or purpose, Logic,
as the science of the regulative laws of thought,
forms a part of the general theory of knowledge.
It holds aloof, however, from the central question
of Epistemology. It presupposes the relation of
our thought to reality, but does not itself investi-
gate that relation, confining itself to the laws by
which we may validly pass from one statement to
another. It occupies a preparatory or introductory
position in relation to the problem of meaning, and
indeed in relation to scientific thought generally.

The History of Philosophy forms not the least
important philosophical discipline. Philosophy
cannot, indeed, be profitably studied apart from
the history of its own development. Speculative
thought has been described to us, and elsewhere, as
but to all intents and purposes the history of philosophy
begins with Thales in Greece about 600 B.C. It is
usual to distinguish three great periods of philo-
sophic thought—Ancient or Greek Philosophy, from
600 B.C. to about 300 B.C.; Medieval Philosophy,
from 300 B.C. to about 1000 A.D.; and Modern
Philosophy, after that date. Greek Philosophy is in turn divided
into three periods—that of the pre-Socratic philo-
sophers (say 600 to 425 B.C.), who devoted their
attention mainly to the phenomena of external
nature. Pythagoras, Heraclitus, Parmenides,
Anaximenes, and Anaxagoras were the most eminent heads of mutually conflicting schools.
The Sophists and Socrates raised the question of
knowledge, turning man’s attention upon himself;
and in the idealistic systems of Plato and Aristotle
(say 400-322 B.C.) we have the great age of Greek
philosophy. In Aristotle the theoretical impulse of
the Greek mind seems to have exhausted itself,
and the post-Aristotelian or third period of Greek
philosophy was mainly inspired by practical need,
by the desire for a theory of life and conduct.
The Stoics, Epicureans, and Sceptics, and later the
Neoplatonists with their religious mysticism, carry
on the tradition of philosophy till the downfall of
the Roman empire and the death of Boethius. After
the so-called dark ages Medieval Philosophy may
be said to begin. From 600-1000 A.D., which was the
Scots Erigena, who is really a Christian Neo-
platonist. Medieval philosophy is mainly the
application of the Aristotelian logic to the
doctrines of the church, and latterly (when the other
treatises of Aristotle became known in western
Europe) exhausted itself in an elaborate attempt
to harmonize the philosophy of Aristotle with
Christian theology. Anselm and Abelard in the earlier period, Albertus Magnus, Thomas Aquinas, Duns Scotus, after about the age of Dekkman in the later, are probably the greatest and most representative names of the Scholastic philosophy. The Renaissance put an end to Scholasticism, and led, in the 16th and 17th centuries, to various attempts to revive the systems of the older philosophers and to strike a new path; but the age was one of failure, and no effective beginning was made in Modern Philosophy till the commencement of the 17th century. Bacon’s Novum Organum was published in 1620 and Descartes’ Discourse on Method in 1637. Bacon’s investigations were mainly logical and methodological, and Descartes was the real founder of modern philosophy. Cartesianism was developed on the Continent into the great monistic system of Spinoza, from which the monadistic or individualistic theory of Leibnitz was a reaction. In England philosophy took an epistemological and even psychical direction. The greater part of Locke’s work was continued by Berkeley and Hume, who developed Locke’s dualism into subjective idealism and scepticism respectively. Hume’s sceptical analysis of knowledge gave rise by revulsion to the Critical philosophy of Kant, which combines elements both from the Continental and the English line of thought. From it sprang the idealistic developments of German thought in Fichte, Schelling, and Hegel, and also the realistic systems of Schopenhauer and Hartmann. Herbart and Lotze represent a realism of a more individualistic cast, which affiliates itself directly to Leibnitz, and is comparatively little influenced by Kantian thought. Scottish philosophy has maintained the reality of knowledge and the dualism of experience in answer to the scepticism of Hume, but like English philosophy generally has been mainly psychological in character. It has been utilized in this way not only parallel to the vast metaphysical systems which have succeeded one another in Germany.

The best general histories of philosophy are by Erdmann, Ueberweg, and Schwägerl, all accessible in English translation. The most recent part of Locke’s exhaustive history of Greek philosophy has also been translated. See also the following articles, and works there cited:

Philostratus of Lemnos, a famous Greek sophist and rhetorician, was born probably about 170-180 a.d., studied under Proclus at Athens, and finally established himself in Rome, where he became a member of the learned circle that gathered round the Empress Julia Domna, wife of Severus. He was alive, according to Suidas, in the time of the Emperor Philip (244-249). His extant works are an idealised life of Apollonius of Tyana; the Imagines, a declamatory exercise on Homer’s Injustice to Phædæus; and a series of oratory and somewhat strained riddles.

There is a good edition of forty-four pictures attached to re-hung in a villa near Naples; the Lives of the Sophists, a series of bright and interesting sketches; the Hermias, a declamatory exercise on Homer’s Injustice to Phædæus; and a series of oratory and somewhat strained riddles.

Philpotts, or Philpotts, Henry, was born at Bridgwater, 6th May 1778, studied at Corpus Christi College, Oxford, and was elected Fellow of Magdalen College in 1795. He became Master of Magdalen College in 1809, Dean of Chester in 1828, and Bishop of Exeter in 1831. A zealous Tory, an extreme High Churchman, and combative by disposition, he was ever the foremost in opposition to measures of reform, and his name would survive if only for his ‘Philopatris’ and ‘Philopatris’ (now &c.). He was for not believing in baptismal regeneration. Yet if he was narrow he was devoted and sincere, his standard of a bishop’s duties was an unusually high one, and he was much beloved throughout his diocese, situated near Torquay, 18th September 1860. See his Life, Times, and Writings, by the Rev. R. X. Slutte (vol. i. 1863).

Philtre (Gr. φιλτρον, ‘love-charm’). A superstitious belief in the efficacy of certain artificial means of inspiring and securing love seems to have been generally prevalent from very early times; and among the Greeks and Romans love-charms, are extensively preserved. It is not certainly known of what these love-potions were composed, but there is no doubt that certain poisonous or deleterious herbs and drugs were among their chief ingredients, to which other substances, animal as well as vegetable, are said to have been added, coupled with the employment of magick rites. Thessaly had the credit of producing the most potent herbs, and her people were notorious as the most skilful practitioners of magic arts, whence the well-known ‘Thessala philtra’ of Juvenal (vi. 610). These potions were violent and dangerous drinks, and their use, in the weakening of the mental powers, madness, and death instead of the purpose for which they were intended. Lucertius is said to have been driven mad by a love-potion, and to have died by his own hand in consequence. In the corrupt and licentious days of the Roman empire the manufacture of love-charms of all kinds seems to have been carried on as a regular trade, the purchasers, if not the makers of them, being chiefly women. The use of philtras seems to have been not unknown during the middle ages; and in the East, the more superstitious nations, the power of love-potions linger down to the present day.

Philips, or PHIPPS, SIR WILLIAM, governor of Massachusetts, was born at Pembury (Bristol), Maine, on 24 February 1651, one of twenty-one boys in a family of twenty-six children. He was successively a shepherd, a carpenter, and a trader, and in 1671 recovered from a wrecked Spanish ship off the Bahamas balloon, plate, and treasure valued at £200,000; this gained him a knighthood and the appointment of sheriff of New England. In 1690 he captured Port Royal (now Annapolis) in Nova Scotia, but failed in the following year in a naval attack upon Quebec. In 1692, through the influence of Increase Mather (q.v.), he was appointed governor of Massachusetts. He changed the manner of the witchcraft persecutions by appointing a commission of seven magistrates to try cases; and he died on 18th February 1714, at Bridgewater, Whitley, where he had been summoned to answer certain charges of arbitrary conduct. See Life by F. Bowen in Sparks’ American Biography (1834-37).

Phiz. See BROWNE (HAIRLOT K.).

Phlebitis (Gr. φλεβίθης, ‘a vein’), inflammation of the veins, although seldom an original or idiopathic disease, is a frequent sequence of wounds, and is not uncommon after delivery. The disease
PHLAEOLITES

PHOCION

is indicated by great tenderness and pain along the course of the affected vessel, which feels like a hard knotted cord, and rolls under the fingers. See Vains.

Phleboites (Gr. phebe, 'a vein,' and lithos, 'a stone') are calcareous concretions formed by the degeneration of coagulations in veins, or occasionally originating in the coats of the vessel.

Phlebotomy, or VEINECTION, is, as applied to human beings, treated at BLEEDING, Vol. II, p. 221. The abstraction of blood was at one time considered, say from 3 to 6 or even 8 quarts, the cord tied round the animal's neck below the seat of the intended operation. This cord should be from 4 to 6 inches in length, and short enough to arrest the flow of blood and cause the vein to become distended and tense. It should then be opened with the 'blood stick,' so as to pierce the skin and vein at one blow.

When a sufficient quantity of blood has been abstracted, say from 3 to 6 or even 8 quarts, the cord is slowly slackened so as to prevent a vacuum and the ingress of air into the vein, the lips of the wound brought into opposition and maintained there by a pin passed through them, and around it twine or tow is twisted in the form of a figure of 8. The pin should not be removed for at least thirty hours.

Phleg'cthon (i.e. 'the dwelling'), a river of the infernal regions, whose waves rolled torrents of fire. Nothing would grow on its scorchcd and desolate shores. After a course contrary to the Corinthus, it descended itself, like the latter stream, into the Lake of Acheron.

Phleum. See TIMOTHY GLASS.

Phlogiston (Gr. phlogistos) was the term employed by Stahl, professor of Halle, in his Zynograteincm Fundamentalis (1697), to designate a hypothetical element which, by combining with a body, rendered it combustible, and which occasional combustion by its diacquayg, there being left, after its evolution, either an acid or an earth.

Thus, sulphur, according to the phlogistic theory— which held undivided sway in chemistry until the time of Lavoisier, who substituted for it the theory of oxygenation (1775-51), heat was maintained by a few chemists, especially Priestley, till the breaking up of the 19th century—was composed of sulphuric acid and phlogiston; lead, of the calx or earth of lead and phlogiston; &c. In consequence of the general adoption of the phlogistic theory, when Priestley, in 1774, discovered oxygen, and when Scheele, a little later, discovered chlorine, the names these chemists gave to their discoveries were deplogisticated air and deplogisticated marine acid. According to modern views, mainly based on Lavoisier's experiments, the addition of oxygen takes place in the formation of acids and of earths, instead of the subtraction of phlogiston.

The question whether the process was, in fact, one of addition or subtraction was finally decided by the balance, an instrument to which chemistry owes most of its marvellous progress during the last three centuries of a quarter. See CHEMISTRY, Vol. III, p. 146.

Phlox. a genus of plants of the natural order Polemoniaceae distinguished by a prismatic calyx, salver-shaped corolla, and unequal filaments. The species are pretty numerous, mostly perennial plants, with simple leaves, and mostly natives of North America. A number of species are common in British flower-gardens. It has of late become a favourite genus with florists, and many very fine varieties have been produced.

Phlox. See DYEING.

Phoece, the most northerly of the Ionian cities in Asia Minor, originally a colony from Athens. It stood on a peninsula between the gulfs of Elais and Smyrna, and had an excellent harbour; and the Phocaeans were distinguished among the Greeks for their nautical enterprise. When the city was besieged by the Persians in the time of Cyrus, many of its inhabitants emigrated to Corsica; Massilins (Marseilles) was a Phocean colony. The old city survived till the later empire; its ruins are still known as Koradesci Tokia.

Phocera. See PORPOSE.

Phocas, a tyrannical emperor of Constantineople (602-610). See BYZANTINE EMPIRE.

Phocidae. See SEAL.

Phocion (Gr. Phòkìos), an Athenian general, was born about the end of the 6th century B.C. He was of humble origin, but studied under Plato, Xenocrates, and perhaps Diogenes also. Phocion first attracted notice in the great sea-fight at Naxos (376), where he commanded a division of the Athenian fleet. In 331, along with Evagoras, he undertook the conquest of Cyprus for the Persian monarch, Artaxerxes III., and was completely successful. In 341 he was successful in crushing the Macedonian party in Euboea and in restoring the ascendency of Athens. Two years before this he had achieved a similar result at Megara; and in 340, sent to the aid of the Byzantines against Philip, he forced Philip to abandon the siege, and even to evacuate the Chersonesus. Nevertheless, he advocated, even in the midst of his triumphs, the establishment of better relations with the enemy, for he had come under the influence of the philosophical reaction in favour of monarchy in stead of a democracy of petty aims and degenerate character. He had come to see that a voluntary acquiescence in the supremacy of an enlightened ruler was better for Athens and for Greece than a hopeless struggle in defence of a political system that had lost its virtue. His advice was not taken; but the fatal battle of Charonea, only two years afterwards, in which the independence of the Greek republics was lost for ever, proved his soundness.

After the murder of Philip in 336 we see him struggling at Athens to repress what appeared to him the reckless desire for war on the part of the fanatical patriots, on account of which he was regarded as a traitor; but his personal honour is above suspicion. On the death of Alexander in 323
the aged Phocion endeavoured, but in vain, to hinder the Athenians from going to war with Antipater. After Antipater's death he was involved in the intrigues of Cassander, the rival of Poly- sperchon, and was forced to flee to Phocis, where Polysperchon delivered him up to the Athenians. He was put to death by a mob of disfran- chised citizens, foreigners, and slaves 'to drink hem- lock. His body, having buried over the borders of the state, was carried by some of his friends to Eleusis, and burned there. The Athenians soon began to raise monuments to his memory. His life and death are treated of in the lurid hue Phociai and seine neuen Beutheiter, by Jacob Bernays (1881).

Phocis, a province of ancient Greece, west of Bocotis, and bounded S. by the Gulf of Corinth. The greater part of the country is occupied by the mountain-range of Parnassus (q.v.). The state derives its chief historical importance from possess- ing the famous oracle of Delphi (q.v.). During the Peloponnesian war the Phocians were close allies of the Athenians. In the time of Philip of Macedon they were involved in a ten years' war, on account of their opposition to a decree of the Athenian government, compelling the use of a piece of land belonging to the temple of Delphi. This war, commonly known as the Sacred or Phocian War, ended disastrously for the Phocians, the whole of whose cities (twenty-two in number) were destroyed, with one exception, and the inhab- itants parcelled out among the hamlets. Phocis and Phthia, among a form of modern Greece.

Phocus (i.e. 'the Bright'), an epithet, and subsequently a name, of Apollo. It had reference both to the youthful beauty of the god and to the radiance of the sun, when, latterly, Apollo became identified with Helios, the sun-god.

Phoenicia, the Φωνια of the Greeks, the Phoeniç, or (sometimes) the Phoenici of the Romans, was a tract of country, lying to the north of Palestine, along the coast of the Mediterranean Sea, bounded by that sea westwards, and eastwards extending to the mountain-crests of Berytus and Lebanon. The limits of the tract northward and southward were not, as is commonly supposed, determined by rivers, and no doubt varied at different periods; but modern researches seem to indicate that the actual Phoenician occupation did not extend beyond the river Litania (Latakia) on the north and Acre, or at the utmost Carmel, on the south. This would give the coast-line a length of about 200, or, counting main indentations, of 230 miles—a fair mean between the 120 miles of Mr Grote (History of Greece, vol. iii. p. 354) and the 300 of some writers. The width between the coast and the mountain- ridges of Berytus and Lebanon varies from 8 to 10 to 25 or 30 miles, perhaps averaging 15 miles. The area of Phoenicia proper may thus be reckoned at about 3000 sq. m. The tract included within these limits is one of a remarkably diversified character. Lofty mountain, steep wooded hill, chalky slope, river valley, broad plain, and sandy shore succeed each other, each having its own climate, while these are hanged by contrast. The sand is confined to a comparatively narrow strip along the seacoast, and to the sites of ancient harbours now filled up. It is exceedingly fine and of excellent silicious quality, especially in the vicinity of Beirut, and at the foot of Mount Carmel. The most remarkable plains are those of Acre, Tyre,Sidon, Beyrut, and Marathus—none of them very extensive, but richly fertile, and capable of producing, under any tolera- ble system of cultivation, luxuriant crops. From the edges of these plains, and sometimes from the very shore of the sea, rise up chalky slopes or steep rounded hills, which at the present day are partly left to nature and covered with trees and shrubs, partly cultivated and studded with villages. The hilly region forms generally an intermediate tract between the high mountains and the plains; but not infrequently it consists of level, rich soil, and fills the undulations the whole space, leaving not even a strip of lowland. This is especially the case in the central region between Beyrut and Arka, opposite the highest portion of the Lebanon; and again in the north, between Cape Pessidi and Jebili, opposite the more northern part of Berytus. The hilly region in these places is a broad tract of alternate wooded heights and deep romantic valleys, with streams murmuring amid their shades. Sometimes the hills are cultivated in terraces, on which grow vines and olives, but more often they remain in their pristine condition, clothed with masses of tangled under-wood.

From the hilly tract, which increases in elevation as it recedes from the shore, rise the two great mountain-regions, separated by a clearly- marked basin, called the plain of Phoenicia in 34 29' north latitude, which runs the river Eleuthers. The more north- ern of the two was known to the ancients as Berytus, and in modern geography bears the name of the Ansarieh or Nasarieh mountain-region. It extends from the Orontes near Antioch to the violet Eleuthers, a distance of less than 100 miles, looking down eastward on the lower Cale-Syrian valley, and westward on the undulating tract known as 'Northern Phoenicia.' Though not comparable to Lebanon, it is a romantic and picturesque region. The lower spurs towards the west are clothed almost entirely with vineyards, or covered with myrtles and rhodo- dendrons; between them are broad open valleys, productive of tobacco and corn. Higher up the scenery becomes wild and bold; forests of fir and pine abound, and creep up the mountain-side, in places almost to the summit; while here and there bare masses of rock protrude themselves, and crag and cliff rise into the clouds that hang about the loftiest summits. But the glory of Phoenicia is Lebanon. Extended in a continuous line for a distance of 130 miles, with an average elevation of over 8000 ft. above the sea, and on its eastern side, it formed a wall against which the waves of eastern invasion naturally broke. The flood of conquest swept along its eastern flank, down the broad vale of the Buka's, and then over the hills of Galilee; but its drowning precipices and its lofty crags deterred or baffled the invader, and the smiling region between its summit and the Mediterranean was, in the early times at any rate, but rarely traversed by a hostile army. This western region it was which held these inexhaustible stores of forest trees and woods, of iron and copper, of wheat and corn; and to the west she ministered the fruits and corn of her immense commercial navy; here were the most productive valleys, the vineyards and the olive-grounds; and here, too, were the streams and rills, the dashing cascades, the lovely delts, the deep gorges, and the magnificent cedars which gave her the palm or all the surrounding countries for variety of picturesque scenery. The principal rivers of Phoenicia were, in the north, the Badés or Nahr-el-Melk, 6 miles south of Jebili; the Nahr Amrith, a strong-running stream which reaches the sea a few miles south of Tortosa and the Nahr of the Arab Fares and the Nahr Kanso, which joins the Nahr Amrith near its mouth; and the Eleuthers or Nahr-el-Kebir, which reaches the sea a little north of Arka. In the central region are the Nahr-el-Beiril or river of Orthosa; the Kudisha or river of Tripolis; the Ibrahim or Adonis; the Nahr-el-Keib or Lycus; the river of Beyrut or
Magoras; and the Damour or Tamyras. Finally, towards the south are the Nahar-el-Anu or Bostrenus; the river of Sidon; the Litany or river of Tyre; the Zaherany or river of Sarepta; and the Biq Jezzar, or river of Ake (Akko). These rivers, except the Litany, range from the sea to the mountains. From the mountain-chains near their crest, and run in deep-wooded valleys, at right angles to the axis of the chains, which is from north to south, having short courses, but conveying generally a good body of water. The last two issues on the eastern flank of the mountain and, running into the Cedars, formed the Cèle-Syrian valley between Lebanon and Anti-Libanus for a distance of 60 miles, turns suddenly to the west, and passes by a deep gorge through the roots of Lebanon to the sea. The Phoenician seacoast is but slightly indented, and possesses few but prominent headlands. The most important are Carmel, if that may be reckoned to Phoenicia; the Ras-el-Abiad, 10 miles south of Tyre; the Ras-el-Jajunieh, a little north of Sidon; the Beyrouth promontory; and in the north Cape Pessis. Of natural harbours we are wanting, except where littoral islands offered a protection from the prevalent winds, as at Tyre and Aradus; elsewhere nature provided nothing better than open roadsteads; and the famous harbours of the Phoenicians were all of them the work of art.

The geology of Lebanon is tolerably simple. Both Barygus and Lebanon are longitudinal ranges of the early cretaceous limestone, a limestone that is soft and pliable, very easily worked, but wanting the qualities needed for the initiatory arts. This simple formation is, however, intruded upon by some masses of igneous origin, especially in the lower ridges. 'Down many of the valleys run long streams of trap or basalt; occasionally there are dykes of porphyry and greenstone, and then patches of sandstone, before the limestone and flint rock.' (Tristram, Land of Israel, p. 634.) Some slopes are composed entirely of soft sandstone; many patches are of a hard metallic-sounding trap or porphyry; but the predominant formation is a greasy or powdery limestone, and this is the sole material of the higher ranges. The softest of all the ranges of Lebanon. The limestone of a rapid vegetation and the accumulation of vegetable soil, which, washed down by the rivers, covers the more open valleys and the plains which fringe the coast with an alluvium of the most productive character. Its mountain-regions must also have furnished Pli Planta, the inexhaustible supply of excellent timber—fir, pine, and cedar; the lower slopes of its hills were admirably adapted for the cultivation of the olive and the vine, while its maritime plains were equally fitted for the growth of corn and of almost every kind of fruit and vegetable. In mineral products it may have been deficient; but the sandstone of the Lebanon is often largely impregnated with iron, and some strata towards the southern end of the mountain are said to produce as much as 60 per cent. of pure iron ore. An oomorphous earth is also found in the hills above which gives from 50 to 60 per cent. of metal. Coal, too, has been found in the same locality. Finally, the geologist Fras has recently discovered immemorable traces of amber-digging on the Phoenician coast. It may be gathered that rare substances were also in the early times among Phoenician products.

Race and Language. — The Phoenicians have been regarded by some as a nation of Hamitic origin, akin to the Egyptians, chiefly on the ground that Sinitc is the only language which bears any marked resemblance to the fifth chapter of Genesis (verses 6 and 15). But the evidence of language, of physical type, and of mental characteristics far outweighs this argument, which assumes that Genesis is framed on strict ethnographic lines, which is disputable. Hence there is a very general, if not a universal, agreement among the more recent ethnologists that the Phoenicians belonged to the Semitic group of races. (Deutsch, Biblical Geog.; Jules Robert.) Unless historical grounds can be shown for the belief that a nation at some period of its existence changed its language, the form and type of its speech must be regarded as determining, almost beyond a doubt, its ethnography. Now the Semitic character of Phoenician language is indisputable. It is so closely akin to Hebrew that a moderate Hebrew scholar can understand it without difficulty. Gesenius first, and since his time Schroder and Reman, having subjected the extant remains to the most skilful analysis, have satisfactorily shown that Phoenician is predominantly and essentially Semitic, without traces of any non-Semitic form of speech. Next to Hebrew, its relations are most close with the Assyro-Babylonian form of the Semitic. See Semites (Vol. i. p. 310) and The Hebrew Language and Written Speeches of the Ancients.

Religion. — The Phoenicians were a people whose minds religion and religious ideas occupied a very prominent place. In all their cities the temple was the centre of attraction, and the piety of the citizens adorned every temple with abundant and costly offerings. The enumeration of the gods of the various states showed the greatest zeal in continually maintaining the honour of the gods, repaired and beautified the sacred buildings, and occasionally added to their kingly dignity the highly esteemed office of high-priest (Menand. Ephes. Fr. 1). The coinage of the country bore religious emblems, and proclaimed the fact that the cities regarded themselves as under the protection of this or that deity. Both the kings and their subjects commonly bore religious names—names which designated them as the worshippers, or placed them under the tutelage, of some god or goddess. Ab-adlomon, Abd-astartus, Abd-osiris, Abdi-milkut, Abd-esmun are names of the former kind; Abibael ('Baal is my father'), Ith'o-bal ('With him is Baal'), Balsezar ('Baal protects'), names of the latter kind. The temple observances were so numerous that it would be impossible to enumerate them. The worship of a number of gods was worshiped with the same rites and with the same observances. But, while we have ample evidence of the religiousness of the Phoenicians, the distinctive character of their religion still remains a matter of controversy. This arises, on the one hand, from the quaintness, jejuneness, and almost stereotyped character of the native notices, and, on the other, from the distorted and misleading account of the religion which has come down to us from a Hellenized Phoenician of the first or second century after our era, Philo of Byblus. A very less reliable and equally fallacious writer, 'that this writer, from whose work, disfigured as it is by his euhemerism, much more, we are told, may be gathered than some have supposed, if we only read it rightly. But it is exactly this necessity of reading into Philo what is not there that misleads the reader on his journey through the religious systems of antiquity. It is only when corralorated by other writers, or by the native remains, that Philo's statements have any value. The native remains show us that in the later historical times, for which alone they exist, the shrunken and localized form of the polytheistic nature-worship of a somewhat narrow character. There is reason to believe that, like so many other polytheisms, it had an earlier monotheistic stage. Of this stage
PHENICIA

the names Baal, El, El-Eholon, Rimmon, Molech, Adonai are traces (Max-Müller, Science of Religion, p. 171 et seq.). Another trace is found in the qinm names of Tyrian and Ashtoreth. Their glass was of three kinds, transparent colourless glass, translucent coloured glass, and opaque coloured glass, scarcely distinguishable from porcelain. The first they used chiefly for mirrors (Hlin. Hist. Nat. xxvii. 26); the second for beads, for imitations of gems, and inlays, jugs, vases, and amphorae, which are often of extraordinary beauty. Opaque glass was employed in statues and statuettes. The Phœnician purple dye was derived, principally if not entirely, from two shell-fish which were abundant in the Eastern Mediterranean, the Murc trunculata and the Murex brandaris. From these, even after careful treatment, a number of tints, varying from blue, through violet and purple, to crimson and rose, were produced, and, by different processes, rendered at once brilliant and permanent. With the purple-dye manufactories was closely connected the manufacture of textile fabrics, wherein the Phœnicians appear to have excelled. White wool from Syria (Ezek. xxvii. 18) and Arabia (ibid. ver. 21), flax from Egypt, and silk from Persia furnished the materials which were worked into stuffs of excellent quality by the Tyrian and Sidonian artisans, who, perhaps by dint of their skill in embroidery, obtained for these stuffs a precedence over the products of the looms of Egypt and Babylon. Phœnicia also manufactured on a large scale all manner of household utensils and implements, partly in clay, partly in metal, together with armaments of various kinds, for the purposes of the export trade which she carried on with barbarous and semi-civilised countries.

Navigation, Trade, and Colonies.—The Phœnicians appear as navigators in the earliest Greek (Hom. Odys. iv. 415—494), and in some of the earliest Hebrew (2 Chron. ii. 14) notices. They were regarded as familiar with the sea in times anterior to the Trojan war (Herod. i. 1). At first, no doubt, their navigation was timid and cautious. But after a time they became bolder. They sailed direct from headland to headland, and from their own coasts to the Euxine, and 70 miles down the Rhone, and even continued their voyages during the night, and after a while adventured themselves in the open sea, directing their course by the Polar star, which they found to mark approximately the true north in the seas to which they had to go. Their ships, though small, according to Polybius, well built and admirably fitted up and arranged (Xen. Econom. sect. 8). For trading purposes they employed ships of a broad, round make (γαδός), but in war they used galleys of a considerable length, which were ordinarily propelled by oars, the rowers sitting on a level, or else in two ranks, one above the other, or sometimes in three. The earliest representations of Phœnecian vessels which have come down to us are in the sculptures of Sargon and Sennacherib (circa 700 B.C.); those of the latter showing a double-tiered galley, which is certainly an established custom (Luc. De Den Syr., sect. 6; Enesch. Vit. Constant. Mag. iii. 55, sect. 3). The institution of the Galli carried out the same idea, and added a final degradation to a system otherwise sufficiently revolting.

Inventions and discoveries.—Two inventions connected with manufactures were especially claimed by the Phœnicians—the invention of glass, and the discovery of the purple dye. Glass is said to have been discovered accidentally on the Phœnician coast (see GLASS); but as the Egyptians had manufactured glass for many ages before, the Phœnicians occupied the Mediterranean coast, and as there was a very early trade between Phœnicia and Egypt, it is most probable that the Phœnicians borrowed their glass-making from the Egyptians. What was special to Phœnicia in respect of glass was the excellent quality of the siliceous coral, near So reconcile, which was called Balf. Their glass was of three kinds, transparent colourless glass, translucent coloured glass, and opaque coloured glass, scarcely distinguishable from porcelain. The first they used chiefly for mirrors (Hlin. Hist. Nat. xxvii. 26); the second for beads, for imitations of gems, and inlays, jugs, vases, and amphorae, which are often of extraordinary beauty. Opaque glass was employed in statues and statuettes. The Phœnician purple dye was derived, principally if not entirely, from two shell-fish which were abundant in the Eastern Mediterranean, the Murc trunculata and the Murex brandaris. From these, even after careful treatment, a number of tints, varying from blue, through violet and purple, to crimson and rose, were produced, and, by different processes, rendered at once brilliant and permanent. With the purple-dye manufactories was closely connected the manufacture of textile fabrics, wherein the Phœnicians appear to have excelled. White wool from Syria (Ezek. xxvii. 18) and Arabia (ibid. ver. 21), flax from Egypt, and silk from Persia furnished the materials which were worked into stuffs of excellent quality by the Tyrian and Sidonian artisans, who, perhaps by dint of their skill in embroidery, obtained for these stuffs a precedence over the products of the looms of Egypt and Babylon. Phœnicia also manufactured on a large scale all manner of household utensils and implements, partly in clay, partly in metal, together with armaments of various kinds, for the purposes of the export trade which she carried on with barbarous and semi-civilised countries.
PHOENICIA

with butz (probably cotton), and with embroidery and precious stones. Syria of Damascus gave the "wine of Helbon" and "white wool." Israel supplied corn of a superior quality, called corn of Minnith," together with pannag, an unknown substance, honey, balz, and oil. Arabia provided spices, as cashmere, musk, and sandal, aromatic reeds, together with frankincense, and perhaps cinnamon and laudanum. She also supplied wool and goats' hair, cloths for chariots, gold, wrought-iron, and precious stones, together with ivory and ebony, which she furnished imported from Assyria, Babylon and Assyria furnished wrappings of blue, embroidered work, and chests of rich apparel. Upper Mesopotamia partook in this traffic. Central Asia Minor, the home of Tuba and Meshech, supplied slaves and vessels of brass. Armenia gave horses and mules of a superior quality. There may have been some further land traffic with Egypt, since the Phoenicians had a settlement at Memphis (Herod. ii. 112), with Persia for silk, and with Central Africa for slaves and skins.

But the land trade of Phoenicia, extensive as we have seen it to have been, was far less than her maritime commerce. There may have been some further land traffic with Egypt, since the Phoenicians had a settlement at Memphis (Herod. ii. 112), with Persia for silk, and with Central Africa for slaves.

like; they assigned to each character a single definite articulation, and to each articulation a single definite character. They thus got rid of the immense multiplicity of earlier systems, and in- 
volved the beauty of simplicity which was transcendent that it has maintained itself ever since, and among civilised nations has superseded every other, having only received certain slight modifications. Their alphabet was invented by the Phenicians for business purposes, which re- quired it, and it was employed almost wholly for business purposes until a comparatively late date. The Phenicians proper, so long as they remained a nation, scarcely possessed anything that we should call a literature. They employed writing for short inscriptions on votive offerings, on tombs, and on coins, for curt records of the history of their country, or rather of their several towns, and no doubt for commercial transactions, but they scarcely wrote books or indulged in what we understand by the art of composition. One work on a philosophic subject (the atomic theory) is assigned to Melchus, a Soledan (Poinset, ap. Strab. vii. 2, sect. 22), and one on religion, or rather on cosmogony, almost certainly apocryphal, to San- chunniati, a Berytian. But otherwise Phenician literature belongs, not to Asia, but to Africa. The fragment of the Periplus of Hanno (q. v.), which contains certain geographical details, is found in Greek of the 4th century, and shows that the Liby-Phenicians at any rate could write interesting books of travels; and the Latin writers speak highly of Heniupael, Mazo, Hamilcare, and others, who had composed valuable works upon the history, geography, and 'origines' of Africa, and also upon ports, in Satull. B. J. xix. 17; Cic. De Orat. i. 58; Amm. Marc. xxii. 13; Solin. Polyhist. sect. 34).

Origin and History.—Two accounts have come down to us of the origin of the Phenicians. According to Herodotus, Strabo, Pliny, and others, they dwelt anciently on the shores of the Persian Gulf (Erythraean Sea), whence they crossed by land to Syria, and settled on the coast of the Mediterranean. Herodotus (vii. 89) declares this to be their own account of themselves, and Strabo saw at Ashkelon a similar inscriptions and monuments of the inhabitants of the gulf, who showed, in proof of it, Phenician temples on some of the islands. Justin, on the contrary, in his epitome of Trogus Pompeius, declares that they were driven out of their country by an earthquake, and passed to the Mediterranean from the Ebro to the Nile. This latter version of the story has been connected by some with the destruction of the Cities of the Plain recorded in Genesis. Whichever account be preferred, it would seem that the Phenicians regarded themselves as immigrants into their country, and not (like most ancient nations) as aboriginals. The settlements upon the Mediterranean coast were no doubt made by degrees, and the settlers at different places were, from the first, independent of each other. Among the earliest of the sites occupied were those of Sidon, Arka, Aradus, and Samsar. Tyre was the latest settled, the earliest settled was so considerably later, and Tripolis was a colony from Tyre, Sidon, and Aradus. Gebal, Akko (Acre), Berytus (Beirut), and Sarepta are mentioned, together with Tyre, in Egyptian inscriptions of the 14th century B.C. (Records of the Past, vol. ii. pp. 112, 113). It would seem about 1000 B.C. that 1300 Phenicia must have been a dependency of Egypt. But on the decline of Egypt under the twelfth dynasty the flourishing time of Phenicia began. Sidon especially grew to greatness, and became known as 'Great Sidon' (Josh. xiii. 18; xix. 28). Under her hegemony Akko, Acreh, and Aplek were able to resist the conquering Israelites (Judges, i. 31). She even at this time pushed her land dominion as far as Dan or Laish, on the head- 
waters of the Jordan (ibid. xviii. 7, 8). Her vessels traversed the Mediterranean, and she became known as the 'Queen of the Sea', the commercial power in the world, and as eminent in various branches of industry. At the same time she began that system of colonisation which Tyre afterwards pursued with so much success. Her emigrants occupied Cithaum and other places in Cyprus, the Egyptian islands, Malta, Uscas, and other places on the North African coast, together with many points in Sicily. She also endeavoured to extend her influence into Phönistia, and, after colonising Dor (SeylaJ, Peripha., sect. 104), made war on Asean. Here, however, she received a rebuff. Her colonies were nearly all burnt by a force under land, and so pressed the siege that the bulk of the citizens fled from the town by sea, and took refuge at Tyre (Justin. xviii. 3), which may thus have acquired her pre-eminence. Certainly in the second period of Phenician history (1592 to 877 B.C.) Tyre rather than Sidon takes the lead. The Tyrian colonies of Thassos, Abdere in Thrace, Proeuctus in Sithyria, Gades, Malaca, Sexti, Carteia, Belon, and a second Abdere in Spain, Caralis in Sardinia, Hudrumetum, and the lesser Leptis in North Africa, Tingis and Lixus on the West Coast of Africa, and Melitene, now Constantine, were founded by Carthage, which had succeeded the kingdom established by Saul and ruled by David (circa 1050) finds Himmon (Hiram) of Tyre a powerful neighbour, and enters into friendly relations with him. The friendship continues under Solomon, and both the Hebrew and the Tyrian annals (Dins., Fr. 2; Menad. Fr. 1) mention the communica- 
tions which took place between them. Hiram gave Solomon timber, and lent him workmen for both his palace and temple, receiving in return large annual payments in corn, wine, and oil, and ultimately obtaining a cession of territory (Gebal), which, however, he did not much value (1 Kings, ix. 10-13). The friendship led on to a participa- 
tion of Solomon in the Tyrian trade, both with Tarshish, or Tartessus, in Spain (ibid. x. 22), and with Ophir, perhaps the coast of Malabar (1 Kings, ix. 20; x. 11). Hiram reigned forty-three years, and governed besides TYA and Gebal, and Saron, and the isles of the sea, which he enlarged by subtractions and by uniting to it a separate island, besides adorning it with new temples, and probably with a new palace. He is thought to have also sent an expedition to Africa, and reduced the people of Utica to subjec- 
tion. Hiram also reigned forty-three years, from about 890 to 836. Balaczer, his son, who succeeded him, reigned seven years, from 836 to 829. Abd-Astuart, Hiram's grandson, then succeeded, and reigned nine years, from 829 to 820, when he was murdered by four of his foster-brothers, the eldest of whom took the throne, and reigned twelve years, from 920 to 908. He was succeeded by a monarch of the ancient stock, Astartus, who also reigned twelve years, from 908 to 896. Aserymus, a brother of Astartus, then mounted the throne, and reigned nine years, from 896 to 887, when he was murdered by another brother, Pheles, who, after a reign of eight months, was in his turn murdered by Ithobal, priest of Ashitareth, who held the throne for thirty-two years, from 887 to 335. Ithobal appears as Eth-baal, and is said king of Sidon 1 King. xviii. 26. He was the king of both cities. He gave his daughter, Jezebel, in marriage to Ahab, and was thus the means of introducing the Baal worship among the Israelites. The foundation of Botrya on the Syrian coast, north of Gebal, and the colonisation of Aliza in Numidia are assigned to him. He was succeeded by his son, Abdecor, who reigned six years, from 855 to 849, and then gave place to his son, Mattan.
PHcenicia

who reigned nine, or more probably twenty-nine years, from 849 to 820. At his death the crown fell to his son, Pygmalmion, a boy of eight or nine years old. A dispute, however, arose about the succession between his two uncles, Sicharbas (married to Pygmalmion's sister Elissa or Dido), and the result was Sicharbas' murder, and the flight of Elissa to the North African coast, where she founded Carthage, 814.

A foreign enemy began to threaten Phcenicia in the time of the late Assyrian monarchs, as Chededaomer and Tigrall-pileser I., had made no permanent impression on the Syrian region; but from the time of Asshur-nazir-pal (883-869) Assyria began a series of attacks upon all the tribes and nations in these parts, which resulted in their subjugation and submission to the Assyrian yoke. Asshur-nazir-pal, about 877, was the first to cross the Enuphates, enter the Orontes valley, and commence the conquest of the Syrian tribes. He received tribute from the Phcenician cities of Aradus, Gebel, Sidon, and Tyre. His son, Shalmaneser II., completed the conquest of Phceninia, defeating Mattai-Caal of Aradus, and compelling the other monarchs to a fixed system of tribute. The relations between Assyria and her vassal then continued peaceful for about a century (840-740). Assyria emerged 849, Phceninia was attacked, and the Phcenicians gladly paid their tribute and their homage in return for the protection afforded them. But about 740 a new policy was adopted. Tigrall-pileser II. was an active and enterprising prince, who energetically applied himself to the consolidation of his own independent monarchy. He began the process in northern Syria, rearranging the population in the various towns, taking from some, and giving to others, adding in most places an Assyrian element, appointing Assyrian governors, and requiring of the inhabitants the performance of service like the Assyrian (Eponyn Canon, p. 120, line 28). Among the places thus treated between 740 and 738 were the Phcenician cities of Sinywa and Arka. The result was a general awakening of distrust among the Phcenian populations. Sinywa and Arka revolted that same year, seeking to throw off the yoke of the Assyrians and to become a free state. Tyre, feeling the threat to her trade, took refuge under her kinsman the distant island of Cyprus. These movements provoked Assyria to action. About 727 Shalmaneser IV., the successor of Tigrall-pileser II., made an attempt to crush Elucines from the land side. Bluffed in this, he succeeded in detaching from the Firmian alliance a number of the minor Phcenician towns, and with the help of their fleets assaulted the island Tyre by sea. But the Tyrians defeated his attack, and he was compelled to withdraw and seek to force them to a surrender by cutting off their supply of water (see Joseph. Ant. 11. xix. 14, sect. 2). But they withstood him for five years, at the end of which the Assyrian monarch lost his throne by a revolution (722), and Tyre was for many years unmolested. At last, however, Sennacherib (cireis 721) felt the necessity of renewing the offensive, and having united against Tyre most of the other southern Phcenician cities, drove Elucines from his throne, and forced him to take refuge in Cyprus. A tranquil period then set in, but only to be followed by further revolts and subductions. In 680 Abil-Melkath, king of Tyre, who had taken the place of Abil-Melkath, joined Tirhakah against his suzerain (Eponyn Canon, p. 142, lines 12, 13), and was severely punished (ibid. pp. 144, 145); and about 645 Hosiah and Akko both revolted against Assar-bani-pal, the son of Esar-haddon, and were defeated, captured, and punished with utter destruction. This Tyranny of the Medes and Persians lasted so fairly in the 9th century, terminated in the 7th in a series of revolts, sieges, and massacres.

The Assyrian power came practically to an end about 633, and Phceninia found herself once more independent. Tyre, never submitted to, occupying the foremost place, and establishing a hegemony over the other cities (Ezek. xxvii. 8-11). But this prosperity and glory were short-lived. Within a brief space Phceninia, and Syria generally, became a bone of contention between Egypt and Phceninia, the two powers which made the earliest efforts to profit by Assyria's fall. First Egypt, under Necho (608), occupied the territory, and then Babylon, under Nebuchadnezzar (605), seized it. Tyre received a grievous blow at the hands of this latter prince, who, after a siege of thirteen years, forced the inland city to surrender to him. Phceninia remained a Babylonian dependent from 585 to 538, when Cyrus took Babylon, despite the efforts of the Egyptians to make themselves masters of it. A fragment of Memondes gives the internal history of Tyre during this interval. Her successors' external position appears, was a second Itholus, who reigned from about 597 to 573. He was succeeded by his son, Baal II., who held the throne for ten years, from 573 to 563. A revolution then took place, Cyrus overthrew the monarchy and placed by judges, others of a inferior status. Of these, Fishilael reigned for about 550, and finished, as he came to Carthage, between two, and Merbital and Gerastatus held it for six years (522-526). But now another internal struggle took place, and the monarchy was restored in the person of a certain Merbal, who was sent for from Babylon, a descendant of the ancient kings. This prince reigned four years, from 556 to 552, and was succeeded by his son, Hiram II., who had a reign of twenty years, from 552 to 552. It was in this latter period that the Babylonian empire came to an end, and Phceninia had another brief interval of independence (530 to 527).

The Babylonian was followed by the Persian period, which lasted from 522 till 333. Phceninia submitted to Cyperus, and became an integral portion of the Persian empire. In the arrangement of the provinces she held a place in the fifth satrapy, which was composed of Syria, Phceninia, Palestine, and Cyprus. She was allowed, however, to keep her native kings, and to organise for internal purposes an native government. Tyre, Sidon, and Aradus united themselves by federal ties, and sent representatives to a common council, which met at Tripolis. An excellent understanding was for some time maintained between the suzerain power and her vassal, who paid a yearly tribute. The period is noted for various maritime wars, forming the main element of her naval strength. It was Phceninia which crushed the Ionian revolt at Lade (495), which caused the failure of the Athenian expeditions to Egypt (478), and in which Cyrus was defeated by the Carthaginian. The Phcenician fleet, gave exceptional privileges to the Phcenian people and states. Phcenian were allowed to settle in Attica, particularly at Phalerum and the Piraeus, to erect tombs there, and have their own place of worship, while ultimately
subject are Mover's Die Phönizier und das Phönizische Altertum (1841-50) and Konrady's History and Inscriptions of Phoenicia (1881). It may perhaps be allowed to add his own History of Phoenicia (1889). There is a valuable article by Mover in the Encyclopædia of Erich and Gruber, and another by his brother in the Ridda, and some excellent essays on the principal characteristics of the Phoenicians, written by Emanuel Deutsch, will be found in his Literary Remains (1874). Recently the attention of scholars has been directed mainly to the three points of the geography of the country, the language and literary remains, and the artistic art and architecture. The geography has been largely illustrated by Pean in his Historie de la Phénicie, Walpole in his Anamurî (1851), by Tristram in his Land of Israel (1885), and by Lortet in La Sprte d'Aujourd'hui (1884). The language and literary remains, which engaged the attention of Gesenius towards the middle of the 19th century, were subjected by him to careful analysis in his important work, Scripturae Linguae Phoenicicae Monumenta (1837), which is still an authority of importance; but the work has since been further carried on with remarkable success by Judas, Études démonstratives de la Langue Phénicienne et de la Langue Lybique (1842); by the Abbé Bourdige Inscriptions Phéniciennes (1852); Dietrich’s Sardesie, by the late H. Weidemann; by J. Ewald, Erklärung der grossen Phönizischen Inschriften von Sidon (1856); by Schröder, Die Phönizisch Sprache (1869); and recently by M. Renan and other scholars in their magnificent Histoire de la Civilisation du Proche-Orient (Paris, 1881-90), where the Phoenician inscriptions occupy almost the entire first volume. Phoenician art and architecture have been largely discussed by M. Renan in his Histoire de Phénicie (1850), treated by M. Clermont-Ganneau in his work, L'imagier Phénicien (Paris, 1880), and by MM. Perrot and Chipiez in their magnificent Histoire de l'Art dans L'Antiquité (1877), where the subject of Phoenicia occupies the third volume. Biographies of Phoenician art have been pursued by General di Cossola in his Cypris (1877), and by his brother, A. d’El costola, in his Sosta (1892); also by Coccadi, Monumenta antiques de Cypris (1889); by Signor Carra di Sorro-ferri (Cagliari, 1875); and by M. de Vogüé, Milanges d’Archéologie Orientale (1890). Research is still going on upon Phoenician sites, as in the vicinity of Byblos and Sidon, and in Egypt and Syria, andweise and the Cyrenaica. The Bybdtal Journal Le Bechit contains from time to time interesting notices of the objects unearthed in Phoenicia proper, while accounts of the work done in Cyprus have appeared in the Times and elsewhere.

Phœnix, the name of a mythical Egyptian bird, supposed to be some to be a kind of plover, like the kible, often said to be associated with a druid in hieroglyphus velch. Others consider it to be the benun, or nytcccicum, a bird sacred to Osiris. It visited Egypt after the death of its father, and entered the shrine particularly dedicated to it at Heliopolis, and there buried its parent, putting the body into an egg or case made of myrrh, and then closing up the egg. Another account is that the Phœnix, when about to die, made a nest for itself in Arabia, from which a new Phœnix sprung of itself. This bird proceeded to Heliopolis, and there more buried its father. But the more popular-known version of schenon (1854), by M. A. d’El crossed all the Phœnix burned itself, and a new and young Phœnix sprang from the ashes. The Phœnix was, according to the most authentic accounts, supposed to visit Egypt every 500 years; the precise period, however, was not known to the Egyptians, and was a subject of contention till its appearance. The Phenician Phœnix was a bird of the theme, and all the Phenician period with that of the Sothic cycle appears to be generally received by chronologists, as well as the statement that it designated the soul and the incubation of the Nile. A great difference of opinion was prevalent about the Phenician period—a cycle generally of 560 years, excised also from 250 to 7000 years. Lepsius makes it a cycle of 1500 years. The Phenician was failed to have four times appeared in Egypt. For

Phœnicien, as in Asia, and where the Phœnicien art and architecture have been largely discussed by Mr. Renan in his Histoire de Phœnicie (1850), treated by M. Clermont-Ganneau in his work, L'imagier Phœnicien (Paris, 1880), and by MM. Perrot and Chipiez in their magnificent Histoire de l'Art dans L'Antiquité (1877), where the subject of Phœnicia occupies the third volume. PHONETICS

Phonetics, the science of the sounds of the voice. These are produced by air sent from the lungs through the windpipe, where it may or may not set in vibration two elastic membranes in the larynx, called the 'vocal cords,' producing 'voice' in the first case, and otherwise a wind-whistle called 'flatus.' After passing the larynx the voice or flatus enters the mouth (the cavity of which, variously modified by the tongue or lips, affects the sound by its 'resonance'), or else the nose (when the entrance to the same from the throat is not blocked by the pressure of the uvula against the back of the pharynx, greatly modifying the sound by the vibration of the complicated membranes which, in the nasal passages), or else both (as in the French nasal vowels). See VOICE, and the illustration of pharynx, uvula, &c. at DIGESTION. Properly speaking, phonetics comprehends the examination of many sounds which are not used in any language, and very different selections have been made by different nations. Here attention is confined to those used in 'received' (as opposed to 'dialectal') English, and a few other European languages.

As the sounds of speech are essentially differentiated by the variously shaped cavities of the mouth, two kinds must be carefully distinguished—'fixed sounds,' where the cavities remain unchanged during utterance; and 'glides,' where the forms of the cavities are constantly changing during the utterance. These glides necessarily occur in passing from one fixed position to another, and very often the fixed position is not used for the production of a fixed speech-sound, but merely for the beginning or end of a gliding sound. Thus, in pot, tok (Italics always indicate systematic writing), the e represents a certain fixed sound known as a 'vowel,' but the p, t, k represent only fixed positions which have absolutely no accompanying sound, and merely begin or end the (unwritten) glides on to and from the vowel. Hence they were called 'consonants' or 'with sounds,' even as much as they sounded with the vowel but not alone. The term 'consonant' has, however, now a much more extended meaning, and the above p, t, k are distinguished as 'mutes.' On the other hand, b, d, g, in bad, bag, have voice-sounds of their own, though very imperfect, and commence and finish the same glides as before, but they are also called consonants, and are distinguished as 'sonants.' Again s, sh, in sash, have distinct hisses of their own, which can be continued any length of time, but also determine glides, and are still called consonants, being distinguished as 'hisses.' Similarly th and f, in thief, 'thief,' are hisses and determine glides on to and from ec. In their there, 'they there,' the kh, are 'buzzes' which can also be continued indefinitely, but have a harsh, grating sound, and when in the same form (but otherwise) easily lose their voice and end in hisses, as hissing, 'his eyes.' The consonants nearest to vowels are the so-called 'liquids'—viz. the two 'flaps,' central r and lateral l, and the three nasals m, ng in roaring, toing, um, um, sung. These are very vowel-like that they can be actually sung upon, especially the three nasals which produce 'hums.'

It would seem to be an easy task to discover at least all the fixed sounds or positions capable of being produced by the organs of speech, and then, noting each by a symbol, leave the glides to form their connection. But it is not so; and had the invention of letters had to depend upon this discovery, we should still have been illiterate. Actually signs were invented for whole words, and then used for the sounds with which they commenced. All was very rough and rude, and the characters chosen could not have been readily altered, even had the requisite knowledge existed. Hence in all languages, and notably in English and French, though the intention of writing was to recall the sound, the word could only be symbolised into representatives of the component sounds, till it came to pass for the above two languages that a word seen and not heard could not be uttered, and a word heard and not seen could not be written. The purpose in this case is the avoidance of recasting orthography by strict analysis of the sounds—i.e. on a phonetic basis—and to print books in accordance with the new conception, in order to teach reading, at least in the first instance, to children and foreigners. These attempts are popularly spoken of as 'phonetics,' but they are only a practical and very small branch of it, to which it is not necessary to allude further. Some of these alphabets are adapted for the scientific expression of speech-sounds, and among them that here printed in italic letters and called 'Glosse,'
which will now be briefly explained and then considered somewhat in detail. The ordinary spelling is given in roman letters, the Glossic below it in Italic.

**SHORT KEY TO GLOSSIC.**

1. **Long stressed vowels** -
   - best, bair, baa, bought, boot, boot.
   - beet, ba'it, bow, ba'at, boot, boot.
   - With vowels - ba'it, ba'at.

2. **Short stressed vowels** -
   - kni, net, gnat, knot, not, nook.

3. **Short unstressed vowels** -
   - merry, parental, influence, follow.
   - mer'I, psar'til, in'foo'sa, fol'oa.

4. **Vowel diphthongs, unanalysed** -
   - file, fell, foul, fuel.
   - feil, foul, foul, feuil.

5. **Aspirate** -
   - hay, behave, mishap.
   - kai, bi-kai'I, mis-kap.

6. **Mutes and sonants** -
   - pea, bee, toe, toe, cape, gape.
   - pee' ber, toe' doa, kai' pi' gip.

7. **Hiess and Bozzes** -
   - whey, way, feel, real, thin then.
   - whai' kai, feel wheel, thin then.
   - seal real, rush rough, lee you.
   - seat zeet, rush roozh, you' soo.

8. **Flaps** -
   - ear' ring, hearing, gull struggle.
   - ear'ring, he'ring, gut strugl.

9. **Nasals** -
   - sum chasm, pan open, sung hunger.
   - sum law'm, pun' oop'n, sung' hung'ry.

10. **Consonantal diphthongs, unanalysed** -
    - chest fetch, jest, judge.
    - chek's fech', jest', juy.

Observe that long vowels under the stress have a turned period (·) after them, and that short vowels under the stress have a turned period after the following consonant. Unstressed short vowels are not particularly indicated here, otherwise than by the stress being marked on some other vowel, except in the ease of a.

The above scheme suffices for received English, but a few more signs, hereafter assigned, are required for some sounds in received German, Italian, Spanish, and French.

The difference between consonants and vowels is only one of degree. Both have their own special resonance cavities through which flatus, whisper, or voice can pass. But the vowel cavities are best adapted to allow the passage of clear smooth voice, capable of being sung upon with a good quality of tone, and the consonants are more adapted for 'hisses,' or that peculiar mixture of flatus and vowels known as 'buzzes.' The 'whisper' proper is a middle kind of sound for which the vocal cords are not brought perfectly close, but close enough to allow the extreme edges of the cords to vibrate in the breath passages, so that a mixture of obstructed flatus and imperfect voice results. Let any one pronounce the above key-words in lines 1 to 4 of the short key in a loud 'stage whisper,' and he will sufficiently seize the effect, which need not be further alluded to, except to draw attention to the difference between whisper and flatus, for the last of which the 'glootie,' or tongue-shaped cavity between the vocal cords, is as widely open as possible, and the sound is produced only by the wind-rush. The reader should try to speak line 1 of the short key with flatus.

The shapes of the resonant cavities of the mouth suitable for vowel-sounds have been analysed by Mr. Melville Bell for his 'Visible Speech' into nine kinds according as the back, middle, or tip of the tongue is high, mid, or low, reekoned from the lower jaw to the palate, the mouth in each case being wide open, and the nasal passages closed. Each of these nine can be modified by more or less closing the lips (called 'rounding'), doubling the former number. Again, each of these eighteen vowels may be either narrow or wide. The best phonetists are not yet agreed respecting the cause of this distinction, but its reality is certain, and may be readily perceived by comparing narrow 'bet' with wide 'bit,' narrow 'ba'it with wide 'beit,' narrow 'mawt' with broad 'not,' narrow pool 'wid' with pool 'pull.' By this means thirty-six vowels are obtained, which again can be varied in different ways. English has only twelve different vowels under the stress as shown in lines 1 and 2, and only four need be noticed when unstressed as shown in line 3. But this is a large number. Other languages have generally fewer, and this makes English so difficult for foreigners to pronounce. A few of the foreign vowels, however, present similar difficulties to Englishmen, among which are the following:

### Additional Vowels

| Short, as distinct from i in Fr. (French) and I. (Italian). |
|---|---|
| ae long in Fr. ba'et, 'bete'; Ger. (German) yeshprack'el, 'Gespäch.' |
| ao short in Ger. man'm, 'Mann'; Fr. aun'mos, 'anno.' |
| ah long and short, Fr. pah, 'pas,' a broad sound between ao and ru., but not rounded. |
| ao long and short or middle length, between ao and ru., Fr. mau'or, 'nord;' Ger. hau'tt, 'Holz.' Also used by older speakers in English as mau'or; now usually ma'oor, 'more.' |
| ee narrow in Fr. peo', 'peu'; Ger. Geot't, 'Goethe,' a narrow without vanish, spoken with the lips rounded as for oo. |
| eo wide, Fr. vor't, 'venve'; Gr. Bock,' 'Böcke,' a wide r, spoken with the lips rounded as for oo. |
| eu long and short, Fr. au'fear, 'affût;' set 'butte'; Ger. uf'lehr, 'über,' wep'lig, 'üppig,' a broad i (or, as Dr. Sweet thinks, a narrow ee), with the lips rounded as for oo. |

### The Four French Nasals

| eon' in raen,'vin,' an attempt to say oe or ou with the nasal passages fully open. |
| aan' or aun' in aan' or ain', 'san,' an attempt to say ae or ah with the nasal passages fully open. |
| eon' or aun' in boen' or bun', 'bon,' an attempt to say oen or oun with the nasal passages fully open. |

When two different vowels glide into each other they form a diphthong. Line 4 of the short key shows the four principal diphthongs purposely noted by arbitrary instead of systematic signs. If we wished to represent their analysis we would write fasl, fasl, fraul, fysoril, where the y and u are to be read as short unstressed, to be followed by the second element, the first element being short but stressed. In the cases of 'way,' 'know,' and similar words, especially in the pause, it is very usual in the south of England to let the voice glide off to a y and sound known as the 'vainting,' but yet not quite so strong as way'y, now.' There are, however, a number of 'murmur diphthongs' where the second element is the murmurr, into which the flap r degenerates (in London, not in Scotland), as shown for ui
in line 8 of the short key, or in the four usual cases—e'z, or e, 'ear, e'zair; ao or ao, 'ear; p's or p's, 'poor.' The r, however, revives if a vowel follows, as he'e, hee'ring, 'hear, hearing, p's or p's, pour, pouring; or p's, p's'ring, more commonly in London.

The name in which a vowel begins to sound is called a 'glottid,' because it depends upon the opening of the glottis. If the vocal cords are quite close and ready to act, as they should always be in singing, the vowel-sound commences immediately on the breath reaching the larynx, and this is called the 'clear' glottid. If the closure of the glottis be exaggerated, so that the vowel comes out with a kind of explosion, the result is the 'catch' glottid, written (') in discussions. This is common before all vowels beginning words or compound parts of words in German, as mae'nyu, ser'tin'brown, 'el'me Erinnerung.'

On the other hand, if the glottis is not quite closed at first, but closes gradually as the breath passes, we have first a slight escape of flatus, followed by a slight whisper, and then by the vowel itself. This forms the 'gradual' glottid, which is not uncommon, especially in passing from a hiss to a vowel, as in see; and even from a mute to a vowel, to distinguish more clearly mutes from sonants, as pes from bee. As a general rule none of these three glottids need be marked, though the 'gradual' may be distinguished in phonetic discussions by ('), as pes, pes'. A similar effect called the 'recoil' occurs after mutes in the pause, and may be written in the same way in discussions; compare pop' with pop'gun, not pop'gun. An exaggeration of this (') often occurs in the so-called 'aspirate' or 'rough breathing,' which essentially consists of a jerked emission of breath, whether voice or flatus, and the exertion of jerking out a vowel often introduces a strong flatus through the vowel position. Both are represented by k (or, when not initial, to prevent confusion, by -k'), but in discussions the latter may be represented by h', as hot, hot.'

The sonants which have positions that gradually diminish in the power of allowing distinct voice to pass from the nasal liquids, as n, through the lateral liquid 1, the flap r, the buzzes, as z, and hisses, as s, to the sonants, as d, and the mutes, as p, may be arranged either as in the short key or by the parts of the vocal organs which form the passage (putting, however, the mutes first as most marked by absolute stoppage of voice) as in the table, where capitals refer to the short key, and the other letters are explained afterwards.

**ADDITIONAL CONSONANTS.**

Col. 2. f', v are f, v without touching the teeth, and of these w is the regular German 'v.' Both occur in modern Greek and Hungarian.

Col. 5. 'd', 'd', 'n' are the common continental forms of our d, t, s, the tip of the tongue being brought more forward, so as to lie fully against the gums. The first two occur dialectically sometimes before r, but are not received. They need not be distinguished from d, t, s, except in discussions.

Col. 6. sh' or sh' pronounced without the hollow at the back of the tongue, which is more in the n-position. But the distinction need not be made except in discussions.

Col. 7. sh are the flapped voiceless forms of s. The first occurs universally in the Welsh 'll,' and the latter dialectically in English for initial 'kn' in 'know.'

Col. 8. 'iy', 'iy' are attempts to pronounce i and a at the same time as y, and hence different from iy, iy in mil'yan, mif'gan, 'million, mine,' where the y follows. They occur as 'ig, gn, in Italian 'gillo, segno, 'igyon, milyan, and Spanish 'el, 'la.

The iy, although still written as 'ill' in French, has of late been replaced in speech by simple y, but ny remains as 'gn; thus, 'allem, 'singer, 'signor, 'signer, etc.

Col. 10. ky, gy are attempts to utter k, g at the same time as y, and used to be heard (may still occasionally be heard), as in 'eart or eart, by the Welsh 'll, and the latter dialectically in English for initial 'kn' in 'know.'

Col. 11. kY, ky are the hissed and buzzed forms of ky, gy in German seck' or secy'k, see'k, 'sich stage,' but ky gY are considered by some (even German) phonetists as the same as y, yh, seck' or see'k.

Scotland. It is the Spanish 'l,' sometimes 'x' or 'tse,' before e, i, as e'kha, keke'shu, 'khus, 'hijo, Quizote, ge'-lef).

'r,' 'r' are flaps made with the uvula instead of the tip of the tongue; 'r' is common in Northumberland, in north France, and in north Germany, where also 'r' is found in the pause, as in 'rily'bi'k, 'richter.'

Col. 12. k'e, q'u' arise from an attempt to utter w at the same time as k, q, and kw', gw' are the corresponding hiss and buzz in German 'auk' or 'auk,' 'zauk' or 'zauk,' 'lauchen, laugen.'

This table is of course very incomplete, but it will serve as a framework for introducing other consonantal sounds. The glides are all these sonants to and from all the vowels should be carefully studied in actual words, but cannot be considered here.

Speech consists of sentences, and it is only by careful analysis that these are separated into words, syllables, glides, and fixed sounds, so that the letters which represent the last only, and have here been treated first, are determined with much difficulty among the mass of sound heard. Any one who attempts to write an unknown language from pure dictation, without seeing its usual writing (if it have one), will feel this immediately. And from this mass of sound to disentangle the words, as they are usually separated, is still more difficult.
An attempt has been made by Dr Sweet for English (Elementarbuch des gesprochenen Englisch, Leip., 1886, and Primer of Spoken English, Oxford, 1890), and by M. Paul Passey for French (Les Sons du Français and Le Français parlé, both 1889), to write exactly what is spoken, dividing the words, commas, etc., by a system of phonetic spelling, and a study of these books will show the difficulty of the problem. The Existing Phonology of English Dialects (1889), by the late Dr Ellis, the writer of this article, shows an attempt to write all English dialects, practically previously unwritten dialects, surfaces, and very difficult it was found, the alphabet here given being quite insufficient for the purpose. For a fuller account of phonetics, reference may be made to his Speech in Song (1878), in which this alphabet is used. See also the articles in this work on ALPHABET, CRIME'S LAW, LETTERS, SHORTHAND, VISIBLE SPEECH, VOICE.

To show the nature of phonetic writing, this rapid sketch of the subject may be concluded with a rough attempt to write received English in the educated colloquial form used in London (not in Scotland).

Example of Phonetic Spelling.

Ab's-fa'ah-le, ei-in-too'a, dâtth-tât: neu'y-br'ah'ah te-on'a'ul Jau'm'ul fu'ul tood'be'en, r'iich is grooitin ni-rih'dah pan pa'ah'el, co'ul to'dar'rih le'rih, moush-k'hih, musk-lih-fah'ah-neer about 'tw-tw, au-mo'lah, in-length th-dahy, un'se sam mi'abap' is skwering aw ur-ti-tud'lah lo-st'se zuhokok vi-tah cuhji: for eir ke-rin'oul tood'ur'rih rai' ah in kree'li-wurk dih'mo'lah, in-mo'lah-di down ak'wuh-ril of-ril, siu-rih-mo'lah in'on'ah'lah in'ah'i-wurk le'mo'lah, in o'mo'sh leh-nin'in, lihning yah, lenning-a der-plee'do' ma'no'ing n'tah-lah lej-ko'ah, poesi'n rai'n.

In ordinary orthography.

Ah! father, I am sure, that that new branch of our country's favourite woodbine, which is growing near the post not far from the north wall of the garden, must be safe from frost, on account of its length to-day, unless some mishap is occurring or it has suddenly lost its usual vital energy; for I have carefully observed its rate of increase every week this month, and noted it down accurately on your slate, and I know it has experienced no variations, barring one, during a desperately nanomigious interval of time, pouring rain.

Phonograph, an ingenious instrument for mechanism recording and reproducing human speech, song, &c. The phonograph was invented by Mr T. A. Edison (q.v.) in the spring of 1877, at his Menlo Park Laboratory, New Jersey, and came to existence as the result of one of the many long series of experiments he was engaged upon. Following up some of his telegraphic inventions, he had developed a machine, which by reason of the indentations made on paper, would transfer a message in Morse characters from one point to another literally, through the agency of a tracing-point connected with a circuit-closing device. Upon revolving with rapidity the cylinder that carried the indented or embossed paper Mr Edison found that the indentations could be reproduced with immense rapidity through the vibration of the tracing-point. He at once saw that he could vibrate a diaphragm by the sound-waves of the voice, and, by means of a stylus attached to the diaphragm, make them record themselves upon an impessible substance placed on the revolving cylinder. The record being made thus, the diaphragm would, when the stylus again traversed the cylinder, be thrown into the same vibrations as before, and the actual reproduction of human speech, or any other sound, would be the result. The invention thought out in this manner was at once tried, with paraffined paper as the receiving material, and afterwards with tinfoil, the experiment proving a remarkable success, and the first phonographs being ready to be sent to Mr Edison in America and Europe, and attracted universal attention. The records were made in these on soft tinfoil sheets fastened around metal cylinders. For a while Mr Edison was compelled to suspend his invention, but soon returned to it and worked out the machine so as to exist practically to-day. It occupies about the same space as a hand sewing-machine. A light tube of wax to slide on and off the cylinder is substituted for the tinfoil, which had been wrapped around, and the indenting stylus is replaced by a minute engraving point. Under the varying pressure of the sound-waves, this point or knife cuts into the tube almost imperceptibly, the waxedelled away wreathing off in very fine spirals before the edge of the little blade, as the cylinder travels under its guidance. It has been possible to record about one thousand words. In the improved machine Mr Edison at first employed two diaphragms in 'spectacle' form, one to receive and the other to reproduce; but he has since combined these in a single efficient attachment. The wax cylinders can be shot through with the usual bellows or by being fitted with a small paring tool which will shave off the record previously made, leaving a smooth new surface. The machine has also been supplemented by the inventor with an ingenious little electric motor with delicate governing mechanism, so that the machine can be regulated at any chosen rate of speed, uniformly. This motor derives its energising current either from an Edison-Lalande primary battery, a storage battery, or an electric-light circuit.

The new and perfected Edison phonograph has already gone into very general use, and hundreds of thousands are distributed in American business offices, where they facilitate correspondence in a variety of ways. They are also employed by stenographers as a help in the transcription of their shorthand notes. New and improved phonographs have been slowly dictated to announcers, but they are now frequently read off to a phonograph, and then written out at leisure. The phonograph is, however, being used for direct stenograph work, and it reported verbatim 40,000 words of discussion at one convention held in 1890, the words being quietly repeated into the machine by the reporter as quickly as they were uttered by the various speakers. A large number of machines are in use by actors, clergymen, musicians, reciters, and others, to improve their elocution and singing. Automatic phonographs are also to be found in many places of public resort, equipped with musical or elocutionary cylinders, which can be heard upon the insertion of a small coin; and miniature phonographs have been applied to dolls and toys. The value of the phonograph in the preservation of dying languages and idioms, for which it has been especially adapted, is manifested by the fact that records have already been secured of the speech, songs, war-cries, and folklore of American tribes now becoming extinct. It is also worthy of note that several voice records remain of distinguished men, who 'being dead yet speak.' Their tones can now be remembered, and, however they may now be lost, and speech can be repeated, they are still, and faithful in accent and individuality, can be heard again and again through all time.

Improvements are being made in the wholesale reproduction of phonographic cylinders, by electrotyping and other processes; and the machine, in a more or less modified form, is being introduced as a
Phosphorescence

Means of furnishing a record of communications through the telephone. Phonographic clocks, books, and other devices have also been invented by Mr Edison, whose discovery is evidently of a generic nature, opening up a large and entirely new field in the arts and sciences. See also TELEPHONE.

Phonography. See SHORTHAND.

Phonolite. See CLINKSTONE.

Phormium. See FLAX (NEW ZEALAND).

Phosphates. See PHOSPHORUS, MANURE.

Phosphatic Diathesis. In Medicine, designates the condition in which there is a tendency in the Urine (q.v.) to deposit white gravel.

Phosphorescence. Strictly speaking, the term is applied to the phenomenon, exhibited by certain bodies, of remaining luminous in the dark for some time after being exposed to a strong light. Certain preparations, such as calcium sulphide (see LUMINOUS PAINT), indurated limestone, &c., possess this property in a very high degree. With the great majority of phosphorescent bodies, however, the phenomenon is very short, rarely more than a small fraction of a second. Bequerel, who studied this phenomenon with great care, invented a very ingenious instrument for the purpose, called a phosphoscope. The body to be tested is placed in a small drum, which has an opening at each end. In this drum there revolve two discs, mounted on the same axle, and pierced symmetrically with the same number of holes. They are so adjusted that when a hole in one disc is opposite to the hole in the corresponding end of the drum, the light of the luminous body at the end of the drum, and vice versa. Light is admitted by one of the holes in the drum so as to fall on the object, and it is examined through the other hole. It is obvious that, when the discs are made to revolve, the object is alternately exposed to light and prevented from it. By a train of revolving wheels, these alternations may be made to succeed each other as rapidly as the observer pleases, and thus the object is presented in the dark to his eye as soon after its exposure to light as may be desired. Almost all bodies are found to be phosphorescent in quinine and certain other highly visible liquids, but in the blue and indigo spaces a strange change of colour is at once apparent where the liquid has been spread. This appears more strongly in the violet, and vividly in the spaces beyond the violet, where rays fall which excite no luminous sensation in the eye, and a certain indistinct visible length of the spectrum may easily be doubled. By using the electric light, which is peculiarly rich in these highly-refrangible rays, a prism of quartz, which allows them to pass very freely, and various fluorescent substances, Stokes has obtained spectra six or eight times as long as those otherwise visible. The characteristic of all these rays is that they are less refrangible than from which they are produced. The entire phenomenon is, as Stokes first showed, identical in principle with Leslie's photometer, in which light was measured when changed into heat by absorption in the coloured glass, of which one of the bulbs of his differential thermometer was formed. Ordinary phosphors (from which the phenomenon took its name) become luminous in the dark by slight friction; whereas the common trick of drawing self-luminous figures on doors and walls with a stick of phosphorus, or an ordinary Lucifer match wetted.

Phosphorescence in Organic Beings.—The emission of light by minerals after insolation and the cognate phenomena of luminosity on heating, friction, cleavage, crystallisation, &c., are of quite different nature from the production of light by organisms, the special subject to which we now turn.

Luminosity due to Interaeaction or to Decay. The fact that many organic substances (especially fish) become luminous when decaying has long been known, and has often been erroneously attributed as the chief cause of the phosphorescence of the sea. It is only quite recently that the discovery of luminous bacteria has led to any general explanation of these facts, and even yet its wide applicability remains to be proved. They have been shown to exist in several instances which will be mentioned below, and the constant association of these low forms of life with phosphorescent processes is suggestive enough to warrant the conclusion that luminosity under such circumstances may be due to their presence. Perhaps they may also account for the few instances in which the human body has been recorded as phosphorescent during life.

Luminosity due to Havana Light.—(1) In the vegetable kingdom the instances of the occurrence of this property are but few, and the majority of these belong to the algea and fungi, the bacilli or bacteria above mentioned being referable to the former. Most of the fungi are Hymenomycetes (Capsaeae, spp.); in some cases the mycelium (root-like threads) gives out the light: in others, as in A. olearius, not uncommon at the roots of olive-trees, it is the under surface of the mushroom-like head. The light is only seen while growth is progressing; it ceases so soon as the fungus is mature. A more or less accurate light is emitted by mosses, grasses, a Euphorbia (E. phosphorea), a Lily (Lilium bulbiferum), a poppy (Papaver orientale), and a masturium (Tropaeolum majus) have all been recorded as luminous. The last instance is worthy of notice as having been observed by the daughter of Linnaeus in 1702.

(2) In the animal world there is not one of the larger groups, up to and including the fishes, which does not afford some good examples of this phenomenon. A complete list of these would be outside the scope of such an article as the present; it must suffice to mention some of the best instances in each class, indicating briefly the nature of the photogenic mechanism. Among the Protozoa the small sphaeroidal Noctiluca militaris is perhaps the most widely spread instance of this property, this organism, or others allied to it, emitting light at certain times around the coasts of the greater part of the world. The light is emitted from the general protoplasm of the body; a pocket-lens shows some points to be brighter than others, whilst a higher magnifying power shows these regions to be groups of very similar forms. Among the Porifera (sponges) the only recorded luminous form is the larva of a species of Reniera. The poverty of this class is,
PHOSPHORESCENCE

The common hydroid colony *Obelia geniculata*, often growing upon the fronds of Laminaria (sea-tangle), is a familiar instance. Numerous Medusae (jelly-fishes) must be added to the list; and here the light is variously emitted in different parts of the organism; (a) from the marginal coruscations; (c) from the radial canals; (d) from the ovaries. Sometimes the same genus includes both luminous and non-luminous forms. *Nemaphora* (sea-pens) furnish instances of the possession of this property; such as *N. excrucians* (Long Island) and on other parts of the Scottish coast, and Pennatula, the subject of classic researches by Panceri, where the light emanates from eight bands or tracts of specially modified tissue situated in the wall of the stomach.

A few species of Ophiurids (brittle stars) and the small pelagic *Phyllorhiza buechula* is of importance, because of the transparency of its tissues permits of its easy study and the successful localisation of its luminosity, which is found to reside in nerve ganglia, as well as in certain small rounded cells situated at the ends of the nerve twigs. The rock-boring bivalve (Pholas) is one of the longest known instances of animal phosphorescence, being recorded by Pliny, who noticed that if any one chewed the animal the whole cheek would glow; though it is now probable that this form the light is emitted from five definite patches all situated within the mantle cavity—(1) an are corresponding with the anterior margin of the mantle, (2, 3) two triangular patches near the opening of the branchial siphon, (4, 5) two long parallel bands within the same siphon. The luminous material is secreted by the epithelial cells covering these portions of the body, and has been shown to consist essentially of two substances, a white crystalline body (luciferine) and a ferment (luciferase); by the mixture of these two in a test tube it is possible to reproduce it without the presence of living matter. The ferment is most likely produced by a certain bacterium, which occurs in large numbers in small pits in the walls of the siphon.

Observations upon baccilli as the cause of phosphorescence have also been made on Crustacea of the genera Talitrus and Orthoplia (sand-hoppers) in a state of disease; the malady, and the consequent luminosity, can be transferred to healthy specimens by inoculation, and the germs can be cultivated by the same method. It would appear that the sand-hoppers infest themselves with the baccilli from dead fish on which they habitually feed. Many other Crustacea, however, are luminous under normal conditions, as, for instance, some Copene (Sapphirina), and more particularly the Schizopoda, one of which, Nyciphanes norvegica, is not uncommon in the deep waters of Loch Fyne as well as on the Norwegian coast. Definite organs (phosphophorina) are here present for the production of light; one in the stalk of each eye, one at the root of each first, and one at the root of each penultimate, thoracic limb, and one accompanied by a large, luminous, and rounded organ in the abdomen. Each organ, as has been proved by microscopic sections, is in reality a miniature half-eye lantern, equally well in complexly by the organs of certain fishes. Several phosphorescent Ascidians are known, the most conspicuous being the pelagic *Ciona*, which has an ovoid external shell, and the animal zoolid has two rounded luminous organs. The researches of the recent deep-sea expeditions have revealed quite a number of phosphorescent fishes, with specialised organs of many different types. Some of these appear to be glindular, whilst others are optical instruments of great complexity, with spherical and paraboloid reflectors to send the light in definite directions and with lenses to concentrate it. In some of the abyssal *Lophiophis* (angler-fish) the modified dorsal fin-ray which acts as a lure has a phosphorescent extremity, no doubt to render it more attractive.

There still remain for consideration the phosphorescent insects, which belong almost exclusively to the Hemiptera (longs) or the Coleoptera (beetles). To the former belong the lantern-flies (Fulgora and allied genera), though it must be mentioned that the possession of this power by these insects has been denied by more than one good observer. Luminous beetles appertain to the families Lamyridae and Elateridae. The glow-worm (*Lampyris specularis*) and the Italian firefly (*Luciola italica*) are good examples of the former, and have been often described as luminous. In both these types are situated in a certain number of the posterior segments of the abdomen, consist of two layers, of which the dorsal contains large quantities of uric acid salts, and the ventral clear cells, which are arranged in cylindrical lobules. In some species both sexes are luminous, in others only one. In the Mexican firefly or Cruyos (*Pyrophorus noctuera*), which belongs to the Elateridae or click-beetles, the organs are three in number, one in each upper and hinder angle of the prothorax, and one much larger occupying the centre of the ventral surface of the abdomen. The organ is invisible while the insect is at rest, but shines forth when it spreads its wings and raises its abdomen in flight. Both the eggs and larvae of this species are luminous.

As regards the physical peculiarity of the light, it varies in colour in different cases, being blue in the mycelium growing in rotten wood, in Cumina, Beroé, Pyrosoma, and Lampyris; green in a species of Agaric, *Pteroclesid*, in Ophiurids, and in *Pyrophorus*; yellow in *Noctiluca*, *Bolu* and with a reddish tinge in a species of *Cestum*, purple in *Punulesis*, but at night blue. In *Noctiluca*, *Oxytella atlantica* and an Appendicularia observed by Giglioli it has been stated that the light varies in color. In all cases in which the matter has been investigated the spectrum has been found to be continuous; the amount of heat given off in phosphorescence with the process seems to be quite infinitesimal, though actinic rays have been shown to be present. The phenomenon would appear to consist in a definite vital process which, in these cases, lends to the production of radiant energy just as other instances to the evolution of heat and electricity.

The uses of this property to its possessors may, so far as is known at present, be grouped under four heads: (a) It enables the sexes to find each other, as in *Lucila* and earthworms; (b) it is possessed by so many stinging *Ctenolentes* that
in them we may fairly regard it as a warning signal, and it may have been adopted by stingless forms for the same purpose by mimicry; (c) it may serve to attract prey, as in the phosphorescent lure of the deep-sea angler-fish (Melnocetus, &c.); (d) it may illuminate the surrounding regions and enable the living phosphorescent forms to swim as in P. ystophorus, Nectyphantes, and many deep-sea fish. So many deep-sea animals are possessed of luminous qualities that it has been assumed that these living lights play an important part in the economy of life in these regions; this hypothesis is confirmed by the discovery of phosphorescent matter in the form of Coprolites (q.v.), or the dung of extinct animals, and more rarely as wavelite (phosphate of alumina) and vivianite (phosphate of iron). In many volcanic rocks vivianite is found in minute crystals or particles, and by the decomposition of these rocks it passes into the soil. From the soil it is extracted by plants, which accumulate it (especially in the seeds of the cereals) in quantity sufficient for the wants of the animals which supply food. In the animal system phosphate of lime forms 57 per cent. of the bones; phosphates of iron in the alkaline fluids of the blood; and in the animal fluids; and in fibrin, albumen, and nervous matter phosphorus is universally present, although we do not clearly know in what form of combination it occurs.

Phosphorus was originally discovered in 1669 by Brandt, a Hamburg chemist, who obtained it from urine. Gahn and Scheebe were, however, the first to discover its presence in bone, and to employ that material for its preparation. The following are the leading steps of the method now usually employed in obtaining it on the large scale. Bones are burned to white ash, and the latter is then mixed with sulphuric acid in such quantity as to decompose the phosphate of lime occurring in the ash, Ca$_3$(PO$_4$)$_2$, partly into insoluble sulphate of lime, partly into a soluble superphosphate of lime, whose composition is represented by the formula $\text{H}_3\text{Ca}(\text{PO}_4)_2$. The solution of the superphosphate is evaporated to a syrup, mixed with charcoal, and submitted to distillation in an earthen retort exposed to a red heat. Phosphorus rises in vapour, and is conveyed by means of a bent tube into water, in which it condenses in yellow droplets. Two distinct processes take place within the retort. The first consists in the decomposition of the superphosphate of lime into bone-earth and hydrated phosphoric acid; while the second consists in the deoxidation, by means of the carbon, of the liberated phosphoric acid into phosphorus—a process accompanied by the evolution of carbonic oxide gas. After being pressed in a fusible state through wash-leather, and further purified, it is forced into tubes, in which it is allowed to solidify, giving it the usual form of sticks. Sombreroite (see APATITE) is now largely substituted for bones in the manufacture of phosphorus.

Phosphorus forms two known oxides—phosphorus anhydride, $\text{P}_2\text{O}_3$, obtained by the slow oxidation of phosphorus in dry air; phosphorus anhydride, $\text{P}_4\text{O}_{10}$, obtained by the combustion of phosphorus in an excess of dry air or oxygen. The latter is a snow-like substance which has a great avidity for water, and is therefore very useful in the laboratory as a desiccating agent.

Phosphorus forms five acids—hypophosphorous acid, $\text{H}_3\text{P(O)}_3\text{H}$, monobasic (the anhydride, $\text{P}_2\text{O}_5$, is not known); phosphoric acid, $\text{H}_3\text{P(O)}_4\text{H}$; phosphorus acid, $\text{H}_2\text{P}_2\text{O}_5$; and phosphorus acid, $\text{H}_2\text{P}_3\text{O}_8$. Phosphorus acid, $\text{H}_2\text{P}_2\text{O}_5$, obtained by dissolving $\text{P}_2\text{O}_5$ in water or by heating ordinary phosphoric acid to redness; pyrophos-

Photius, Photius of Constantinople at a critical period, was a member of a patrician family of Constantinople, and was born in the early part of the 9th century. Distinguished by his abilities, he served in various important public offices, and secured the favour of the Emperor Michael and his powerful favourite Bardas. The patriarch Ignatius, having in vain tried to correct the vices of the profligate emperor, was banished, and Photius, though a layman, was appointed in his stead, hurried in a few successive days through all the stages of sacred orders, and finally installed as patriarch. Two successive councils of bishops under court influence confirmed the deposition of Ignatius and the election of Photius. In 882, however, Pope Nicholai 1. (q.v.) called a new council at Rome, which declared Photius' election uncanonical and invalid, deposed and excommunicated him, and reinstated Ignatius in his see. Being supported, however, by the emperor, Photius retained possession of the see, and called a council at Constantinople in 867, in which he raised a controversy of doctrine and discipline between the churches of the East and West themselves. In all these doctrinal differences the council condemned the Western Church, excommunicated Nicholas and his adherents, and withdrew from the communion of the see of Rome. Michael being put to death by Basilius the Macedonian in 867, Photius was banished to Cyprus, and Ignatius reinstated; and in 869 the eighth general council, at which Pope Adrian II.'s legates presided, was assembled at Constantinople. Photius was again condemned and excommunicated, and the intercommunion of the churches restored. Yet on the death of Ignatius Photius was reappointed to the patriarchate. In 879 he assembled a new council at Constantinople, renewed the charge against the Western Church, and excommunicated the creed in the article, 'the Procession of the Holy Ghost' the word filioque (see Spirit). The separation of the churches, however, was not completed till the time of Michael Cerularius (see Greek Church). Photius was finally deposed, and exiled to Ararat in 885. He was afterwards pardoned by Michael, and died soon afterwards, probably in 891. His chief remains are Myriobiblon, called also Bibliotheca, a summary review of 279 works which Photius had read, many of which are now lost; a Lexicon; the Nomocanon, which is a collection of the acts and decrees of the councils and ecclesiastical laws of the emperors; several minor theological treatises; and a collection of letters, many of them extremely interesting and elegant. See Hergenrother's monograph on Photius (1869).

Photography, the art of producing pictures by means of the action of light on sensitised surfaces. Its origin is as ancient as the science to which it belongs, and was the monopoly of the alchemists of the 16th century that Vauque Cornet or Horn Silver (native chloride of silver) was blackened on exposure to light, as the first chemical step in the history of photography, while the formation of photographic copies was laid by Della Porta in the invention of the camera obscura (1569) at a somewhat earlier period. This property of chloride of silver, and also the darkening of nitrate of silver by light in the presence of organic matter, constitute the leading facts on which the science of photography is based. In 1777 the famous Swedish chemist Scheele found, by experiment, that Horn Silver was blackened quickest at the violet end of the solar spectrum, thus proving that the rays of light are not all alike chemically active. A quarter of a century later Ritter of Jena demonstrated the existence of chemically active invisible rays beyond the violet rays of the spectrum.

The honour of being the first to produce pictures by the action of light on a sensitive surface is now very generally conceded to Thomas Wedgwood, an account of whose researches was published in 1802 in the Journal of the Royal Institution, under the title, 'An Account of a Method of copying Paintings upon Glass, and of
making Profiles by the agency of Light upon Nitrate of Silver; with Observations by H. Davy.' The misfortune was that no attempts made either by Weiglond or Davy to prevent the uncoloured portions from exposing the plate, which we now say, to fix the picture) were successful.

Niepce Niepe of Châlon-sur-Saône was the first to enjoy the satisfaction of producing permanent pictures by the influence of solar radiations. This was accomplished in 1814, and the name chosen to denote such substances, which devoured the sun's rays, consisted of coating a piece of plated silver or glass with asphaltum (bitumen). The plate so prepared was then exposed in the camera obscura for a length of time, varying from four to six hours. Wherever the light acted it rendered the asphaltum insoluble in its usual solvents, and the lights were represented by the insoluble asphaltum remaining on the plate.

Daguerre appears to have begun in 1824 the experiments which eventually led to the discovery of the daguerreotype process. On Daguerre learning that Niepce was working in the same direction as himself, the two formed a partnership in 1829. The discovery of the Daguerreotype (q.v.) was announced in January 1839, though the details of the process were not made public till August of that same year. It consists in exposing a metal plate covered with iodide of silver for a suitable time in a photographic camera, the plate being afterwards transferred to a dark room, and exposed to the vapours of mercuric iodide, which changes the latent image into a positive. It was then dipped in a solution of nitrate of silver, which is changed by the action of the common salt into the chloride of silver, some of the nitrate, however, remaining unaltered. Paper so treated is sensitive to light, so that when a fern-leaf, for example, is placed close down upon two plates of glass, and daylight is allowed to act on the prepared surface, the paper-blackens except where it is covered, and thus a reversed picture of the leaf on a black ground is obtained. This was then placed over another sheet of paper, prepared in the same way, and the light allowed to act through it. Another picture of the leaf was thus produced, but this time with its lights and shades the same as in nature. The white image on a dark ground was called by Fox Talbot a negative, and the print from it he called a positive. These terms are still current in photography; the negative image being produced in the camera, as the first and leading operation—any number of positives being obtainable from it on paper, glass, or any other material capable of forming a support for a photographic image. The Calotype process was patented by Talbot in 1841. In this process Talbot produced his negative by preparing paper on the surface with iodide of silver, subsequently washing it over with a mixture of nitrate of silver, with gallic and acetic acids, and then exposing it in the camera to the object he wished to copy. The invisible image or picture thus obtained was developed by acetate-nitrate of silver and gallic acid. The paper negative was then rendered translucent with wax, and used for the production of many positives in the way described above. The introduction of collodion by Archer marked the next great step in photographic progress, and this, known as the wet-plate process, is now almost universally used.

Photographic Apparatus.—The most important piece of apparatus used by the photographer is a form of the Camera Obscura (q.v.), generally called simply a camera, with its attached lens that throws the image on a glass plate or horned sheet of paper. It consists of a box to enable it to be sharply focussed. A thin flat box with a shutter, together called a dark slide or 'back,' contains the sensitised plate. When the picture is focussed the screen is withdrawn and the 'back' inserted in its place; the shutter is then drawn out, and the sensitised plate, which exactly occupies the place of the glass screen, being now exposed, receives the picture. In a brief time, which nowadays varies from a fraction of one to several seconds in a good light, the shutter is closed, and the slide returned to a room illuminated by a light not chemically active, generally red, orange or yellow green, where the plate is taken out and developed.

The introduction of dry plates for photography, which may be used in the camera a long time after their preparation, has had a great influence in modifying apparatus and rendering the photographic process almost true of the photographic camera. Under the older system (wet-plate photography) the plate had to be used immediately after it had been coated and furnished with its sensitive film, or it became useless. Once dried, however, the plate could be stored during exposure was therefore all that was necessary, for only one plate could be prepared and used at a time, a dark room or tent being necessary for the operations. But now that the plates will keep almost indefinitely between preparation and use, any convenient number can be made ready for insertion in the camera, to be exposed to the action of the light one after another. For this purpose what are called double dark backs are employed, each holding two plates—one on each side, and each side being furnished with a light-proof shutter which can be opened to allow the lens to cast the image on the plate inside as soon as the back is fixed on the camera.

Much ingenuity has been applied to camera construction of late years, but, although many new modes of carrying the plates and bringing them under the influence of the rays have been devised, the double-back system, as just described, is the one most generally adopted when glass plates are employed. Various changing-boxes have been devised, which contain a dozen or more plates, and dispense with all but one dark slide, that is constructed to receive and discharge any plate of the series at will. Hare's changing-box is the one most generally known. This has a special form of dark back, which can be charged with one plate from the box at a time, and is then inserted in the camera for the exposure. Recent improvements in photographic apparatus have been largely adopted whereby the camera itself becomes a storage for the plates, a simple mechanical arrangement permitting the exposed plate to fall to the bottom while another plate occupies its place.

But the most recent change in photographic apparatus is due to the introduction, or rather the revival, of sensitive films supported, not on glass, but on a flexible material. We have already seen that Fox Talbot employed paper for his negatives; and, although paper was superseded by glass when the collodion process came into existence, photographers were quick to recognise that such a brittle material had serious disadvantages. Many experimenters endeavoured to produce or find some
PHOTOGRAPHY

material which, while possessing the transparency of glass, should be of a less brittle nature, and among these Mr Woodbury in 1876 produced such a compound from collodion, castor-oil, and Canada balsam. This mixture, after being heated to a temperature on a sheet of paper sensitive to light, and after again being dried was stripped from its support and cut into suitable sizes for the camera. It is noteworthy also that the inventor at the same time proposed that such films, being perfectly flexible, might be wound and unreel on the same cabinet as that containing the camera; and thus, the long roll of sensitized film might be submitted to the luminous image, and thus the whole business of changing plates be accomplished by the turn of a handle outside the apparatus. The same idea was taken up by Warnecke a few years later, and his patented roll-slide became obtainable commercially. Warnecke also made a sensitive dry collodion film for use in his apparatus, but its cost—which was at the rate of a penny per square inch—limited its use to a few.

To Messrs Morgan & Keil of Richmond belong the honour of being first to apply gelatine to photographic sensitiveness. The paper is now made by many dealers, and is commonly called bromide paper. Its principal use is for enlarging, but at the time of its introduction it was used for negative work, the paper being rendered semi-transparent by an alkaline agent or gum arabic. In any case, too, after the work the inventors employed a roller-slide of the kind suggested by Woodbury. The Eastman Company next took up the matter, introduced a roll-slide, together with a paper film of very reliable quality. This paper is sold in spools, and is known as the Eastman paper; the buyer had merely to take a spool from its case, insert it in the roll-slide, and he immediately had material ready for reeling off forty or fifty negatives, to be subsequently separated by cutting, developed, and rendered transparent with a preparation of vaseline. These films have been described to be made on account of the trace of grain from the paper which was left on the picture printed from it, and a 'stripping film' was next adopted as previously proposed by the Rev. W. Palmer. By this modification the surface bearing the image could be stripped from the plate and retransferred to sheet paper, insoluble gelatine, which became its final support. Film photography has recently been brought to still greater perfection by the employment of transparent and flexible celluloid in sheet form. It is curious to note that this substance, invented by Parkes, was long considered as an inefficient substance for use in photography, and it would doubtless have been so used if collodion, when applied to it, had not had a solvent action. But as it is quite insoluble in water, it forms a perfect support for a gelatine film, and now that it can be manufactured nearly as clear as glass, it represents the best thing yet introduced. Its general use is limited by its cost, which is greatly in excess of glass, but it presents so many advantages that it is very largely employed. The material is now made thin enough to be wound on spools and used in roll-holders. Beyond the advantage of lightness, portability, freedom from breakage, reduced cost of carriage, &c., which the films undoubtedly possess, there is one gain in their employment, of a technical nature, which is important enough to receive recognition here. They are free from halo- tions. Having a surface that approximates very closely to that of glass plates as an encroachment of the light parts upon the dark portions, and is seen in its most aggravated form in the blurring out of windows in interior views. It is caused chiefly by reflection of light upon the glass.

The great rapidity of modern dry plates allows a photograph to be taken in such a mere fraction of a second that the camera can be held in the hand during the operation. Various hand-cameras are now made, and meet with extensive employment, especially by tourists, and are more or less dismissed by experienced men; but they are becoming so common that the disagreable is more apparent than real.

The extreme sensitiveness of modern dry plates has also given rise to what is known as flash-light pictures, which are photographs taken by the aid of an instantaneous flash produced by scattering powdered magnesium into a lamp-flame. Many ingenious forms of lamps have been devised for this purpose. They mostly consist of a spirit-lamp in conjunction with a receptacle for the magnesium powder, with a pneumatic ball and tube attached. Pressure on the ball distributes the powder, and carries it into the flame. This system is much used for taking groups and portraits at night in private and public rooms. The best workers employ a branch tube from the ball, which exposes the lens at the moment of maximum light. Lens combinations designed for this purpose is of great importance. An explanation of the different forms and properties of Lenses is given under that head, but it is necessary to say a few words here about the kinds used in photography. They may be divided into two classes—portrait and landscape lenses. The portrait lenses cover a large aperture, but give a small image; while the latter have a small aperture, but give an image which covers a far larger surface. In the portrait lens rapidity of action has been the chief thing considered, for it is used in a studio where the amount of light available is always more or less limited. A portrait lens unless of the 'doublet' form is not suitable for view purposes; but a view lens can well be used for portraiture under certain conditions, and is one of the best lenses to use for groups. Under the head of view lenses come a large number which have fanciful names attached to them that are apt to mislead the tyro, but which are all more or less alike. In the early days of photography telescopic objectives were made to do duty in the camera, but they gave a very small field, and were in other respects unsuited to the purposes of photography. The Petzval lens, designed by Petzval, and made by Voigtländer of Vienna, an invention which marks an era in photographic progress. The single view lens, which is the cheapest and for pure landscape is still unequalled, had its first improvement in the patent granted to Dallmeyer who placed a meniscus lens made by Grubb in 1857. Although called a single lens, it consists of a combination of crown glass of concavo-convex form, cemented to a flint divergent meniscus. The single lens was modified later on by Dallmeyer, who subsequently, in 1888, introduced a new form of view lens which, possessing the usual advantages, had the quality, hitherto unknown in a single landscape lens, of giving an image free from enurlinmal distortion. The same feature had been secured by Dallmeyer in his well-known triplet lens, which was invented in 1860, and which, as its name implies, consisted of three combinations. This lens was serviceable for copying, architectural subjects, as well as for landscape, and was a great favourite with photographers. It has now been superseded by the doublet form of lens, which, under the name of rectilinear, symmetrical, &c., is the most commonly used form of photographic lens. It possesses two positive and two negative combinations of similar construction placed with their concave surfaces facing one another, the necessary stops or diaphragms for increasing definition and reducing spherical aberration being inserted in a slit in the brass mounting tube midway between them. These lenses are constructed to take different angles of view, according to the require-
ment of a given case: for taking subjects in a confined situation, such as a narrow street, or for depicting the façade of a large building at very limited range, a ‘wide-angle’ lens is necessary. For the convenience of those carrying a number of lenses, Heinrich Oskar von Studnitz invented a kind of non-removable lens that will fit all flange. Every lens is fitted with a set of diaphragms or stops; and, in the case of the lens last mentioned, these usually take the form of a rotating plate, pierced with the necessary apertures. But in other lenses the diaphragms are in the form of separate plates, and are kept in a small leather case by themselves, the operator removing any of the series, and inserting it in the lens when wanted. These diaphragms are marked with what is known as their focal value, which means that the number marked represents the fraction which the aperture of the diaphragm is of the focal length of the lens. To make this plain, let us suppose that the focal length of the lens is 6 inches, and that the diaphragm in question has an aperture of a quarter of an inch. As there are in 6 inches 24 of such quarter inches, the figure 24 will represent its value, and this will be expressed thus: 24. In like manner, a half-inch diaphragm would be marked $\frac{1}{12}$, and a one-eighth inch diaphragm $\frac{1}{48}$.

There is, however, another method of marking lens stops, which has been adopted by the Photographic Society of Great Britain, and which is called the ‘Uniform Standard,’ or U.S. for short. In this system $\frac{1}{4}$ is called No. 1, and the U.S. number for any other size is found by dividing the focal length of the lens by the diameter of the stop, as already described, squaring the result, and then dividing by 16. Of late years a remarkable improvement, which, however, had for some time been applied to microscopes, has been made in photographic lens diaphragms, in a contrivance which, from its resemblance to the natural diaphragm of the eye, which expands or contracts automatically according to the amount of light to which the organ is subjected, is called the iris diaphragm. This consists of a number of flat blades or tongues of thin blackened metal, which are preferably to be used in the lens mount. By a turn of this ring the blades are expanded or contracted, so that the aperture can be enlarged or diminished as required, while a scale marked on the outside of the lens mount, and a travelling pointer, indicate the focal value of every change of aperture. Wet negatives on glass, and occasionally on leather or in lens manufacture—the introduction of aluminum instead of brass for the necessary metal work, by which the weight of the instrument is greatly reduced. The same useful metal, only now rendered available by its cheaper manufacture, is also coming into use as a substitute for brass in the other metal fittings of cameras. A new kind of glass, known as Jenia optical glass, is now being employed in the construction of photographic lenses. By its use a larger field can be covered with a given aperture than was the case under former conditions.

Wet-collodion Process.—Collodion (q.v.) is the name given to the solution of pyroxyline, a kind of gun-cotton, in a mixture of ether and alcohol. When this is flowed over a glass plate it gradually dries and adheres to the plate. It was first produced for photographic purposes in 1851 by Mr. Scott Archer, and has been of great and important service. For nearly a quarter of a century the wet-collodion process was almost exclusively practised by photographers—in the earlier years for the production of positives on glass, and occasionally on leather or other non-fragile materials; latterly by modifications the process was more extensively employed for the production of negatives. Dry-collodion processes have also been in use, although on a much more limited scale. These are the stages in the wet-collodion process: (1) A glass plate made perfectly clean is coated with collodion, to which the bromide of cadmium and either iodide of potassium or iodide of ammonium is added. The coated plate is ‘sensitised’ by immersion in a bath of nitrate of silver, containing 33 grains to every ounce of distilled water. (2) Production of latent image by exposing the sensitised plate in the camera after the object has been focused. (3) Development of latent into visible image by flooding the plate with a solution of sulphate of iron (ferrous sulphate), or of pyrogallic acid, to either of which some acetic or citric acid is added. (4) Fixing of the permanent image by immersion of the plate in some solvent of those parts of the sensitive surface upon which the light has not acted. This solvent for wet plates is cyanide of potassium, but for modern processes hypo sulphite of soda is employed.

Dry-plate Processes.—It is hardly necessary to do more than name a few of the earlier dry-plate processes; since, a number of dry plates have all been beaten out of the field by the recent one known as the gelatino-bromide process. Several advantages arise, especially for field-work, from using dry sensitive plates. With the wet process the operator, when away from his studio, must keep his plates in a dark tent, or dark, and developing agents, besides a supply of water for washing purposes; but these impediments are not required with dry plates. Dry-plate processes are of two principal kinds: (1) Those in which the collodion is applied to the glass plate, and afterwards sensitised in the silver bath, as in the wet method, but with a ‘preservative’ such as albumen ‘flowed’ over the surface, and the plate allowed to dry. (2) Emulsion processes, in which the sensitive silver salt is held in suspension in the collodion or gelatine. A good emulsion can be prepared by adding some soluble bromide, such as bromide of cadmium, to the collodion, and afterwards an alcoholic solution of nitrate of silver. The glass plates are simply coated with this emulsion, washed in water to remove the soluble salts, and set aside to dry, when they are ready for use. The gelatin-bromide emulsion process is still employed to a limited extent, chiefly for the production of transparencies; recent experiments indicate that it may yet compete with gelatino emulsion in sensitiveness.

The earliest form of the gelatino-bromide process, at present so universally employed, appears to be due to Dr. Maddox, who published the details of a workable emulsion of this nature in 1871. The process was improved in 1873 by Mr. Bennett, and again in 1878 by Mr. Charles Bennett. It was found that if the emulsion was kept at a temperature of 90° F. for some days, or boiled for half an hour, the sensitiveness of the plate coated by it was so greatly increased that a view which could only be taken formerly in 30 seconds could now be taken in one. A very sensitive gelatino emulsion can also be formed by boiling a solution of gelatino and a solution of silver. Dry plates produced by some form of the gelatino-bromide process are now manufactured on a large scale. When properly made they will keep good for years, and they can be developed months after having been exposed. But it is generally admitted that the emulsion products obtained when the plates are not old, and when development follows exposure without undue delay.
PHOTOGRAPHY

the paper was salted only—i.e. the albumen was dispensed with—and this old method is being largely revived.)

(2) Silvering of the paper by floating it on a solution of silver, from 30 to 60 grains of this substance being used for every ounce of water, according to the amount and kind of chloride in the paper. It is afterwards dried.

(3) Exposure to light. The silvered paper is exposed beneath the negative in a printing frame, the place of exposure varying according to the brightness of the light and the character of the negative.

(4) Toning. In order to give a pleasing colour to the print it is usual to tone it in a solution of chloride of gold. Quite recently the metal platinum has been used for toning silver prints on plain paper with very fine results. One method has been introduced by Blanchard, and another by Lyonel Clark, the latter employing the same salt, the chloro-platinite of potassium, which is used for the platinum printing process to be presently described.

(5) Fixing. The print, when taken from the toning bath, is steeped in a solution of hyposulphite of soda, which removes the undarkened silver salt that is still sensitive to light, and so fixes the image.

(6) Washing. Silver prints require to be washed quickly and fairly long treatment with the hyposulphite of soda. Prolonged soaking is harmful, and imperfectly washed prints soon spot and fade. Gelatino is now largely coming into use as a substitute for albumen: it is more suitable for the rendering of delicate detail, and the prints with it can be exposed in their production ought to be more permanent. The papers known as Aristotype, Argentotype, and Celerotype are gelatine emulsions of chloride of silver spread on paper.

Printing in Salts of Iron.—The metal iron in some of its chemical preparations is now very largely employed in a number of photographic printing processes—e.g. cyanotype, chrysotype, kallitype, platinitotype, &c.—and is capable of producing results with all the fidelity and delicacy of the silver process, in some cases at considerably less cost, while the manipulations are greatly simplified. The principle involved is next to be considered as known as ferric salts, that are not affected in appearance when certain other chemicals are brought in contact with them; other preparations of iron, known as ferrous salts, produce highly-coloured pigments when combined with these same chemicals.

The action of light can change ferric into ferrous salts; hence, if a piece of paper be coated with a ferric salt, dried, and placed under a fern leaf, a piece of lace, or a photographic negative, and exposed to light, an image in a ferric salt is produced which is capable of being developed into a highly-coloured image when acted on by a suitable reagent; and not only so, but, as this reagent has no action on the ferric salt, they may be mixed together in the first instance and thus applied to the purpose when the action of light will develop the highly-coloured image, a simple wash in water completing the operation. This is in outline what is known as the Cyanotype or Blue printing process, first published by Sir J. F. W. Herschel in 1842, which in detail is as follows:

The cyanotype is made on a support containing sixty-four grains of ammonio-citrate of iron to the ounce of water, the other forty-eight grains of ferrocyanide of potassium to the ounce of water. Mix equal quantities of these solutions, and with a soft sponge or flat camel-hair brush quickly and evenly cover one side of good smooth white paper. This is best done by gas or candle light; then place to dry where it will not be affected by daylight. Then paper so prepared is chiefly used for copying plans and drawings on tracing cloth: the tracing, which should be in a good opaque black ink, is placed on top of the paper, and both are covered with a second sheet of cyanotype paper. Ten minutes in a very bright light will suffice for exposure. The print is now washed, when the lines of the drawing will appear white on a blue ground. The same kind of paper can be exposed beneath a photographic negative in order to secure a rough copy of the picture, but in this case the time of exposure is much increased.

A disadvantage of the above process is that the original black drawing on white paper appears as a white drawing on a dark-blue ground.

The following modification, known as the Pollet process, produces blue prints on white paper: Gum arabic, 25 parts; common salt, 3 parts; perchloride of iron, 8 parts; tartaric acid, 4 parts; and water to make up to 100 parts. Well-sized paper is coated with the above and treated as in the preceding; it is not sensitive to light. A good tracing on bright sunlight is sufficiently printed in from ten to fifteen seconds. The print is developed by immersion in a saturated solution of ferro-cyanamide of potassium (yellow prussiate), and the design immediately appears in blue. The print is now rinsed in cold water, and then transferred to a 10 per cent. solution of oxalic acid: a third rinse in cold water completes the operation.

Chromotype.—This is a modification of cyanotype, also published by Sir J. Herschel. The paper is merely coated with the ferric ammonium citrate, and may be developed after exposure with a neutral solution of gold chloride, washed with water and dried. The resulting print is in metallic gold in a finely-divided state, and is of a fine purple colour. A dilute solution of nitrate of silver may be substituted for the gold when the image is in metallic silver.

Kallitype.—In this process paper is washed with a strong solution of neutral ferric oxalate. After printing in the usual way, it is developed by the following solution: Nitrate of silver, 50 grains; citrate of potash, 500 grains; bi-chromate of potash, 1 to 2 grains; rain water, 500; ammonia, 2 parts. The precipitate is next dissolved by the addition of ammonia (strength, 85°) about a drachm will be sufficient. After filtering add 35 drops of strong nitric acid, and the developer is ready. This solution is very cheap and easily prepared. The resulting prints possess a fine rich black effect.

Platinitotype or Platinum Printing Process.—The metal platinum can be deposited from some of its chemical preparations in an extremely fine black powder when brought in contact with one of the iron salts altered by light. Herschel explained how to get prints in platinum, but the process now employed is that discovered by Willis. Captain Abney, F.R.S., thus describes the chemical action upon which the process is based: 'Mr W. Willis, jun., found, that he could obtain an image in platinum black, by means of development, if he sensitized his paper with ferric oxalate, with which was mixed a solution of chloro-platinite of potassium. The action of light on this paper is to reduce the ferric salt to the ferrous state, and when the ferrous salt is in solution the platinum salt is reduced by it. By floating the exposed paper in water on a solution of ferrous oxalate, which is a solvent of the ferrous oxalate, the platinum salt in contact with it is immediately reduced to the metallic state, and an image is thus built up. To fix the prints they are immersed in dilute hydrochloric acid, which dissolves away any ferric oxalate there may be, and also gets rid of any oxalate of lime.'

Paper prepared as above described is supplied com
mercatorially. And after being exposed to light beneath a negative in a printing-frame for about one-third of the time necessary in the case of a print on silivered paper, its lemon-yellow tint is found to change, where the light has reached it, to a pale, dirty-gray colour. Development is conducted in an iron enamelled tray, beneath which a spirit-lamp has been placed to keep the sodium chloride solution at a temperature of about 175° F. Under-exposed prints will benefit by this temperature being exceeded, whilst those which have received more light than they should have had can be advantageously treated by the non-development of telling the other faults of the paper. The print is floated on this warm bath, which turns the faint image of the picture to a dense black, and fixation follows by placing the picture in a series of water baths made slightly acid with hydrochloric acid; these remove the iron from the paper; a simple rinse in plain water completes the operation. The developer can be mixed in bulk, for it keeps well, and the same quantity will develop a large number of prints one after the other. The platinum prepared paper will keep well if damp be excluded. For this reason it is so greatly preferred to silvered paper over an equal quantity of calcium chloride, a salt which is so greedy of moisture that it will absorb all in its neighbourhood. The favour with which this process has been received, because of its permanence and its quick results, is well indicated at photographs. Indeed, no other process has the pictures shown invariably platotypes. Mr Willis, the inventor, has introduced a cold bath platinum process, in which the metallic salt is contained in the developer, and this modified method is said to present many advantages. The developer thus prepared not only hardens the photographic image, but also may be mixed to meet the existing demand. Another modification of the platinum process, made known by Willis, but more generally associated with the name of Captain Pizzelli, yields a dark image in the printing-frame. The only necessary after-treatment is a bath of weak acid, followed by washing in plain water. There is every reason to suppose that platinum will be the printing process of the future, but unfortunately the price of the metal, which in 1890 was 100 per cent. calculated for the present to limit its use.

Bichromated Gelatine Process.—So far back as 1839 Mungo Ponton announced that paper steeped in bichromate of potash and dried changed its colour when exposed to light. It was subsequently discovered that soluble parts of the composition of the bichromate, but also oxidises the size (gelatine) of the paper. Gum, starch, and allum were also found to become, like gelatine, insoluble when exposed in contact with the bichromate of potash or ammonia to the action of light. If ordinary gelatine be soaked in cold water, it absorbs the water and swells, and then if heated, or if hot water be poured on it, the gelatine melts. If some bichromate of potassium or ammonium had been added to the cold water, the gelatine would re-precipitate the chemical along with the water. If now the gelatine be dried, and then heated until the stain imparted by the bichromate is altered in colour, it will no longer swell in cold water, neither will it dissolve in hot water; the action of light has made the bichromated gelatine insoluble. The principle of this chemically modified that we owe the 'autotype' or 'carbon'—more correctly 'pigmented gelatine'—process. The Collotype, Woodburytype, and some forms of photocoloured engraving and photogravure, also certain kinds of 'phantom' photographs, and one method for vitreous enamels, depend on the same principle.

The Autotype, Carbon, or Pigmented Gelatine Process.—Pigmented gelatine paper is an article of commerce, and the Autotype Company supply this 'tissue' sensitised ready for printing. The tissue consists of a thick coat of gelatine, with which has been intimately mixed a certain amount of permanent pigment in very fine powder—for if a black, Indian ink be used on gelatine; other colours are added to modify the tint. The gelatine is sensitised with ammonium bichromate, and then exposed under a negative till it is supposed to be sufficiently printed. The image is not visible as in a silver or iron print, therefore some indirect plan of exposure, such as the use of an actinometer, must be resorted to. The change which takes place in the gelatine film is this: the surface next the negative has been rendered insoluble wherever the light has acted, and that to a depth corresponding to the intensity of the light. It results from this that almost the whole of the surface of the gelatine has been rendered insoluble—to the greatest depth where the light has acted most strongly. Soluble portions, however, remain enclosed between its surface and the paper. No picture is visible till these are removed; for over a certain distance (a tenth of an inch or so) from the surface the removal of the soluble portions imprisoned between the insoluble skin and the paper at the back—took many years of experimenting, and all sorts of devices were resorted to. One plan was to expose the back of the tissue to the negative, thus taking the cutout image still leaving the paper showed offensively. Farguez spread the pigmented gelatine on glass, exposed it thus under a negative, and then coated the film with collodion. On subjected the whole to the action of warm water, the latter penetrated the collodion and the pigment was washed out of the glass, being held together by the collodion. This was now supported on paper (collodion side down), and washed from the back with warm water, and so the first half-tone photographs in pigmented gelatine were obtained.

Swan experimented on similar lines, and in 1862 he took out a patent for pigmented gelatine films spread upon collodion supported on glass. When dry the whole was stripped from the glass, and thus the first tissue was made. The difficulty of removing the cutting paper, although at present, and this Swan overcame by coating the collodion surface of his tissue with India-rubber solution, and applying it to a piece of paper similarly coated. When both were dry the whole was passed through a press, and then soaked in warm water; thus the bit watters on the picture in which leaving part of the film acted on by light untouched, and projecting in relief according to the varying action of light as it passed through the gradations of the negative. By this method and a subsequent modification Swan sent out a number of fine pigment prints, but it was so troublesome, expensive, and unsatisfactory in the hands of the average photographic printer that printing by bichromated gelatine never became popular until J. R. Johnson, about the close of the year 1868, discovered that the pigment could be removed after sensitisation by the bichromate and correctly exposed to light under a negative, only required to be soaked in cold water, and then evenly applied to any surface impermeable to air, such as glass, zinc, oilcloth, etc., when the gelatine surface would be printed. The principle of the schoolboy's sucker—by atmospheric pressure alone. Then by soaking in hot water the paper at the back came off, carrying with it much of the matted pigment and gelatine, and by laying the image remaining on the support with the hot water the picture in all its delicate gradations appeared clean and perfect. It was this.
PHOTOGRAPHY

discovery that made what is generally known as autotype or carbon printing a practical working process. The method above described is called the single transfer process, and produces a print reversed as to right and left. The double transfer process merely differs in the adoption of a temporary support of opal glass, zinc, or paper coated with a suitable preparation (the most convenient being Sawyer’s flexible support), which holds the print till developed, and from which the print is then transferred to its final support—it is then non-reversed. When practicable it is usual to take a reversed negative, and thus avoid the double transfer.

Powder Process.—By what is called the powder process prints are produced on paper in phlogosilphg, or any other impalpable powder insoluble in water. It has been a good deal used on the Continent. A slightly sticky or ‘taeky’ preparation of sugar, gum, glycerine, and potassium bichromate, when exposed to light, loses its stickiness in proportion to the intensity of the light acting on it. A glass plate coated with this preparation will therefore, when exposed under a negative, represent the picture, so to speak, by breaking up into tiny fragments, and these fragments of powder, when washed, adhere to the surface of the glass, and give a picture. This kind of powder is made by taking a very thin layer of a metallic oxide, between two glass plates, and crushing the metallic oxide between the plates by pressure. In this way a layer of metallic oxide is obtained, which is then transferred to a glass plate, and when this plate is placed on a support, and exposed to light, the metallic oxide is decomposed and reduced to metallic minute particles, which adhere to the glass plate, and are washed away and dissolved in water, leaving an impression of the negative. This process, however, is too slow, and the method of making the metallic oxide as described is too cumbersome. It is more convenient to make a metallic oxide by evaporating a metallic salt solution on a glass plate, and then exposing this plate to light. In this way a layer of metallic oxide is obtained, which is then transferred to a glass plate, and when this plate is placed on a support, and exposed to light, the metallic oxide is decomposed and reduced to metallic minute particles, which adhere to the glass plate, and are washed away and dissolved in water, leaving an impression of the negative.

Photographic Enamels on Glass and Porcelain.—If the image as described in the preceding paragraph be developed by suitable metallic oxides —such as the underglaze colours of the porcelain paper—coa, the resulting image coated with colloid gelatine, and then coated with a light-sensitive metallic oxide, such as copper, zinc, or any other metallic oxide, will become visible when exposed to light. The light-sensitive metallic oxide becomes decomposed, and is reduced to metallic minute particles, which adhere to the glass plate, and are washed away and dissolved in water, leaving an impression of the negative. This process is too slow, and the method of making the metallic oxide as described is too cumbersome. It is more convenient to make a metallic oxide by evaporating a metallic salt solution on a glass plate, and then exposing this plate to light. In this way a layer of metallic oxide is obtained, which is then transferred to a glass plate, and when this plate is placed on a support, and exposed to light, the metallic oxide is decomposed and reduced to metallic minute particles, which adhere to the glass plate, and are washed away and dissolved in water, leaving an impression of the negative.

Lithotype and Phototype Processes.—Both of these are photo-mechanical methods, in which the gelatine relief is itself used to print from in some form of printing-press, instead of being covered with a carbon print. In the phototype the gelatine relief is obtained by an autotype print instead of a leaf on a flat piece of iron, covering it at the same time with a smooth piece of sheet-lead, and then put them under sufficient pressure, the result would be an imperfect Woodburytype mould in the soft lead. The metal reverse would be faulty, because in this case the gelatine film is too thin to give enough of relief. In order to obtain a proper mould a layer of sensitised gelatine, considerably thicker than that used for an autotype print, is exposed under a negative. It is developed as in the autotype process, and presented in the same way. When the mould is transferred to glass, the print is covered with the lead, and they are pressed together in a hydraulic press, which produces a reverse or mould of the picture in the soft metal without injuring the gelatine relief. The production of ordinary Woodburytype prints is a purely mechanical operation, the chemical action of light not being called into play; they exhibit true gradation of tint, and in that respect Woodburytype is the only perfect photo-mechanical printing known. The mould is placed in a printing-press of a peculiar but simple construction, and a varnish containing the proper printing ink is applied to the mould, which is then allowed to dry. The mould is then placed in the printing-press, and the printing ink is printed on the piece of paper. The ink then adheres to the paper, and the mould presses the ink on to the paper, forming the picture. In this way the mould is transferred to the paper, and the picture is formed.

The production of ordinary Woodburytype prints is a purely mechanical operation, the chemical action of light not being called into play; they exhibit true gradation of tint, and in that respect Woodburytype is the only perfect photo-mechanical printing known. The mould is placed in a printing-press of a peculiar but simple construction, and a varnish containing the proper printing ink is applied to the mould, which is then allowed to dry. The ink then adheres to the paper, and the mould presses the ink on to the paper, forming the picture. In this way the mould is transferred to the paper, and the picture is formed.

Mr. Green, in conjunction with his partners Messrs Cross and Bevan, published the process at a meeting of the British Association at Leeds in 1890.
PHOTOGRAPHY

Photo-lithography and Zineography.—The only difference between these is that a lithographic stone is used in the one case and a plate of zinc in the other for the mechanical printing. It is necessary that the original drawings should be done in lines and not in half-tint. At least, it is doubtful whether much success has as yet attended the production of half-tint photo-lithographs. A negative is taken from the drawing by the camera, and from it for the mechanical printing. It is necessary that the original drawings may be made of any convenient material, and reduced on the wood—a great consideration when minute objects are to be represented. In the first case, one process is first to render the surface of the block waterproof, and then it is whitened with Chinese white. The block is then sensitised with chloride of silver, and printed under a reversed negative. It is then toned with gold and fixed with hyposulphite of soda, washed and dried, and is then ready for the engraver.

In the carbon process, a carbon tissue is made with very little gelatine and a large amount of carbon. It is then sensitised with chloride of silver, and printed on a block printed waterproof and whitened with baryta; the carbon print is developed on the wood with warm water, and, when dry, is ready for the engraver.

Photo-micrography consists in photographing microscopic objects by causing a microscope to take the place of the ordinary photographic lens in the camera, so that the enlarged image is cast upon the sensitive surface of the collodionised or gelatine plate. Such photographs, again enlarged by the optical lantern, are much used for class instruction.

By reversing the arrangement necessary for the enlargement of microscopic objects it will be seen that minute photographs of engravings, or other objects, may be produced which would require a microscope for their inspection. In this way considerable detail may be obtained in the interesting study of Paris, when copies of letters and newspapers were inserted in quills, and fastened to carrier pigeons.

Astronomical Photography.—The application of photography to astronomy has within the past few years opened up a new and a fertile field. Great results have been achieved through the wedging of the camera with the telescope. Until recent times the only remarkable photographs of the celestial bodies were those of the moon, which were executed by Warren de la Rue, Rutherford, and others. The moon being from its size and brightness a comparatively easy body to photograph, the early processes were sufficient for the purpose, and most perfect results were obtained. Janssen and others have secured photographs of the sun which exhibit markings upon its surface with great distinctness, and many photographs of the corona when the orb has been under eclipse have also been taken when the sun's sunspot is present. But it is in picturing the distant stars and nebulae that the greatest work has been achieved by photography, and results obtained which would have been impossible without the aid of the highly sensitive dry plates now at the disposal of the astronomer. Among the triumphs already obtained in this direction may be mentioned Roberts' photograph of the 'Andromeda Nebula,' Common's photograph of the Nebula in Orion, and several similar negatives obtained by the brothers Henry of Paris. One of these last workers, a photographer of the Pleiades, should receive special mention. A certain star in this well-known group appeared in the photograph in question with a nebulous haze attached to it.

This star was not known to be associated with a nebula, and the astronomical community was deavoured to detect it by aid of the smallest powerful telescope at their disposal. The nebulous mass was therefore discredited, until another photograph of the Pleiades arrived shortly afterwards from America, which exhibited exactly the same peculiarity. One of these last, as the astronomer was in the act of discrediting another, and at length was declared to be faintly discernible. From this it would seem that the photographic film is more sensitive to faint impressions than is the retina of the eye, and in a certain sense this is true. These star photographs are often even more striking than the negatives of the distant objects for three or four hours, during which time the clock-work train attached to the telescope keeps the images of the tiny points of light stationary on the plate, in opposition to the rotation of the earth. Each image, however faint, has therefore a comparatively long time to make an impression on the sensitive chemical surface, and exerts a cumulative action, with the result that the images of stars are registered which no human eye has ever beheld. To put the matter more plainly, it may be said that certain sections of the sky covered by these photographic telescopes contain a definite number of stars. When this same space is photographed their number is often doubled. At a convention of astronomers held in Paris in 1887 it was decided to take steps for photographing the whole of the heavens. For this purpose the sky has been charted out into squares, and each observatory helping in the work will photograph a certain number of these spaces. The work is estimated to entail ten years' labour, this long time being partly accounted for by the circumstance that, even during the few hours of clear weather and the interruptions caused by moonlight, there are only about fifty nights in the year when sidereal photography is possible. There are many difficulties in photographing the stars, some of which have led to discussion, and have caused the extreme distance of the bodies to be ascribed to the nature of the atmosphere. It is believed to be due to irradiation, want of complete achromatism in the lenses, and reflection from the back of the photographic plate. These difficulties will no doubt be surmounted in the future, and it may be mentioned...
that they are only observable when a refracting telescope is employed. Hence the use of reflecting telescopes for photography has been suggested; but, although by this means some of the faults mentioned are banished, other inconveniences arise which form obstacles to good work. Dr. Duggins has done much valuable work in photography of the heavenly bodies.

Durability of Photographs has been suggested by the introduction of specially prepared gelatine dry plates—known as orthochromatic ('right colour') or iso-chromatic ('equal colour'), both very vague terms—it is possible to reproduce colours in their true shade relation to one another. For instance, suppose that we seek to photograph the ordinary plate in a vase containing yellow flowers. In the resulting picture the vase will be white and the flowers will be black. But if we use iso-chromatic plates the vase will be rendered as a grey and the flowers will appear almost white, which is obviously the way in which the eye observes the original. This change in the behaviour of the sensitive surface is brought about by adding to the gelatine emulsion of which it is composed a minute quantity of certain dyes. Vogel in 1873 discovered that certain coal tar derivatives produce a change of sensitiveness in silver compounds; and in the same year Talifer and Clayton secured a patent for the preparation of colour-sensitive plates prepared by the same agency. They use an ammonium solution of eosine; and plates made under the patent are now supplied commercially. They are much used in copying all coloured objects, such as oil paintings; and there is little doubt that they will play an important part in sidereal photography, in the registration of coloured stars. Meteorologists are now depending upon photographs obtained from without with pictures of lightning (p. 207). A study of the latter is likely to extend our knowledge concerning the phenomena connected with thunderstorms, and has already elucidated a few problems. Maybridge, in the United States, introduced the system of analysing the form of pitting on a telegraph wire by a trotting horse, running dog, &c. By means of special apparatus he found it possible to take a dozen consecutive pictures of a single movement. Marey of Paris further developed this phase. In the cinematographic a series of photographs taken in rapid successionynuth a moving screen by the aid of a magic-lantern in the same rapid manner in which they were taken, the result being a life-like reproduction of the original scene. Photography through an opaque object by means of the Röntgen rays (see RÖNTGEN) has already been of immense use in surgery in fixing the exact position of a foreign body such as a bullet in the human body as a preliminary to their extraction.

Although photographing in colours has long occupied the attention of scientific photographers, no direct method of doing so has yet been described. One, and perhaps the most important of the indirect methods, is in taking separate (colourless) negatives of a coloured object are taken through coloured screens. From these positives are taken, and colour is supplied by means of inks or dyes. When these three-coloured monochromatic positives are superimposed, and seen by projection on a screen or through a photo-chronoscope, a coloured image of the original is the result.

Photogravure. By this process the finest possible results are obtained, but the expense of producing pictures by its aid, which is akin to the operation of copperplate printing, limits its use to high-class book-work. It is also used by Boussod, Valadon & Co., by Durand of Paris, by the Autotype company, by the commercial printers of Glasgow, and others for the production of large pictures which rival the finest steel engravings in their delicacy and finish. Photographs can be reproduced in this form, but the process seems to be more largely employed for obtaining engraving-like copies of celebrated pictures. The process is so perfect that every touch of the painter's brush is clearly seen in the copy, and even the upstanding ridges of paint in the bolder touches are rigidly reproduced. There are naturally different ways by which printing plates for use in this process are prepared. Of these methods only must here suffice to give an indication of the line of operations. (1) A gelatine relief is obtained by exposing bichromated gelatine to the action of light beneath a negative. But the gelatine employed is mingled with a certain quantity of graphite (black lead) in a more or less granular form. This addition causes the resulting relief to have a surface which is granular in character, and which is also a conducting me to electricity. If therefore the relief be placed in an electrolyte bath it will speedily become covered with a deposit of copper. From this study, and the method so far described, copies on paper can be obtained by the usual copperplate printing process. (2) A bichromated gelatine print—negative in character—is developed upon the specially prepared surface of a copper plate, which is then subjected to the action of a solution of petroleum spirit. The rate at which the negative is dissolved is speeded up or more or less quickly according to its varying thickness, and then attacks the copper, which is eaten away by the chemical action that ensues. Thus in the end the copper plate bears on its surface an etched image, penetrating more or less in depth according to the difference in density of the negative image previously affixed to it. The plate is next 'steelfaced' and printed in the copperplate press. (It is often necessary to resort to hand-finishing in order to get the finest results.)
Photometry (Gr. phōs, 'light,' and metron, 'measure'), the art of measuring the intensity of a source of light, by comparison with a standard of known intensity. In the first experiment the two sources of light are compared by putting them side by side in a scale in which the distances are equal and the apparent diameters proportionate to the intensities of the lights as before and the corresponding vibrations are also compared. It was also found that a very audible sound could be procured from the selenium without the aid of telephone and battery. A beam of intermittent light will produce a strong musical note from the selenium.

Further experiments showed that selenium is not the only substance thus sensitive to light. Still louder sounds than those obtained from the selenium directly, though not articulate, were got from diaphragms of hard india-rubber and of antimony; and sounds of varying intensity were given out by many other substances, including gold, silver, platinum, copper, zinc, lead, paper, parchment, and wood.

**Physphere.** See SUN.

**Phrenology.** (Gr., 'a discourse on the mind') was the name given about 1815 to the theory of mental philosophy founded on the observation and discovery of the functions of the brain concerned in intellectual and emotional phenomena, as formulated by Gall (q.v.) in Britain the system was simply expounded by Gall's pupil Spurzheim (q.v.), by George and Andrew Combe (q.v.), and by Dr. Elliottson, founder and first president of the Phrenological Society; and in America by Dr. Charles Caldwell of Kentucky, the brothers Fowler, and S. R. Wells. The connection of mind and brain was an old theory, and a kind of localisation of mental function in the brain had at various times been attempted from the days of Albertus Magnus downwards; but the first full-fledged system of empirical craniology or phrenology must be attributed to Gall, who established his scheme by his examination of the skulls of persons belonging to different nations, and of persons of different character; and believing himself to find portions of the skull corresponding to their mental and moral faculties, marked out on a model of the head the areas which were in his opinion the seat of the various faculties. These faculties were divided into two orders—Feelings and Intellect, or Affective and Intellectual Faculties. The Feelings were divided into two genera—the Propensities and the Sentiments; while the Intellectual embraced the Perceptive or Knowing and the Reflective Faculties. Various modifications of Gall's scheme of localising the faculties were made by his pupils. American phrenologists (the Fowlers and S. R. Wells) increased the number of the faculties to

Bell, his friends, and assistants devised some fifty forms of apparatus, for so varying the transmission of light to prepared selenium as to produce audible sounds. In this way photophone found most serviceable the transmitter is a plane mirror of silvered micro.

26. Locality.
27. Number.

II.—REFLECTIVE.
28. Comparison.
29. Order.
30. Eventuality.
31. Time. 32. Taste.
33. Language.

PHRYNE

tion the most important feature of the brain. Parts
of the external surface are known to have functions
other than those attributed by phrenologists; the
frontal slims of the skull is sometimes large enough
occupied by the region allotted to four or five phrenol-
logical organs; and there are many osteological
variations in the several bones of the skull which
obviously have nothing to do with brain-functions
or mental processes. An outline of what is known
as to the localisation of brain-functions will be
found in Brain, Vol. II. p. 790. For cranological
characters, see SKULL, ETHNOLOGY; and see also
PHYSIOGNOMY, PSYCHOLOGY.

Phrygia, a country in Asia Minor, the extent
and boundaries of which varied very much at
different periods of ancient history. In probihis-
toric ages it is believed to have comprised the
greater part of the peninsula, but at the time of
the Persian invasion it was limited to the districts
known as Lesser Phrygia and Greater Phrygia—the
former stretching along the shores of the Propontis
and the Hellespont to Tras (afterwards part of
Mysia), the latter occupying the centre of Asia
Minor. Phrygia was in general a high and some-
what barren plateau, though its pastures supported
immense flocks of sheep, noted for the fineness
of their wool. The most fertile part was the valley
of the Sangarius, but the most beautiful and pop-
ulous district was the south-west, at the base of
the Taurus, where the Mysian and other streams
had their rise. The mountains and streams yielded
Phrygian barley was anciently celebrated,
and the cultivation of the vine appears to have
been extensively carried on. The Phrygians were
apparently closely related to the Armenians,
and have left their traces in almost all parts of Asia
Minor. Later they were forced within narrower
limits by the intrusion of Scythian and other aliens
—Lydians, Carians, Thracians. In the 6th century
Cresus conquered all that was left of Phrygia, and
in 549 B.C. it was ceded to the Persians. The influ-
ence of Phrygian religion on Greek mythology
seems to have been great. Among their deities
were Men or Muses, Cybele, and Athys; and
Phrygia was a great centre of orgiastic worship
and celebrations.

Phrygia (1895-97). For the Phrygian Mode, see HAM-
MONY; for the Phrygian cap, see BONNET.

Phryne, a celebrated courtesan, was the daugh-
ter of Iepites, born at Thespiae in Boeotia, and
originally earned a livelihood by gathering vipers
but as the fame of her marvellous beauty spread
she obtained numerous lovers, who lavished gifts
her so profusely that she became enormously
rich. In proof of this the story goes that she
offered to rebuild the walls of Thebes if the citi-
zens would allow her to place this inscription on
them: 'A virtue destroyed, a courtesan, rebuilt.' The Thebans declined
the proposal. Her enemies accused her of prin-
ating the Elusinian mysteries. Summoned before
the tribunal of the Helioots, she was defended by
the rhetorician Hyperides, one of her lovers, who,
perceiving that his eloquence would not avail
the judges, threw off her robe and showed
her naked loveliness. She was immediately
acquitted, and carried in triumph to the Temple of
Phyllophora, the vine, and has cost France alone a pecuniary loss far exceeding that of the Franco-German war. It seems to have been discovered in North America in 1854, and in all likelihood was carried thence to Europe, where it appeared about 1863. It now occurs in all vine-growing countries. In some of its features it is like a little aphids, measuring about 1/4th of an inch in one of its stages, or only a fourth of that in others, varying from yellow to reddish brown in colour. The antennae are thick,

Phrynichus, (1) an Athenian tragic poet, who gained his first dramatic prize in 511 B.C., twelve years before Eschylus, and his last in 476, when Themistocles was his chorasgo. He seems to have gone to the court of Hiero in Sicily, and to have died there. He introduced music representing women, and to the light minuet choras of Theseus added the sublime music of the dithyrambic choruses. His most famous tragedies were the Phoenicis, which is supposed to have inspired the Persae of Eschylus, and another which had for its subject the capture of Miletus by the Persians. So overpowering was its effect that the audience burst into a passion of tears, fined the poet a thousand drachmas for so harrowing a description of the sufferings of a kindred people, and forbade the piece ever again to be represented. His scanty fragments will be found in Nanek's Tragicorum Fragmenta (1586).

(2) A poet of the old Attic comedy, who was honoured by the abuse of his great contemporary Aristophanes (Rut. 14) for his low buffoonery. His fragments are collected in Meinike's Fragmenta Comicaorum Graecorum (1859-57) and Koch's Comicorum Atticorum Fragmenta (1880 et seq.).

(3) A Greek grammarian and sophist who flourished under Marcus Aurelius, and wrote a collection of select specimens of Attic usage intended for the benefit of his friend Cornelius, secretary to the emperor. It consists of almost four hundred short unconnected dicta on the orthography, signification, and use of particular words, and upon the rules of accidence, especially in verbs. The edition by Lobeck (1820) was followed by The New Phrynichus, by W. Gunton Rutherford (1831).

Phthiotic, the south-east corner of Thessaly (q.v.), the home of Achilles.

Phthisis. See CONSUMPTION.

Phylactery (Gr. phosphateira, 'an amulet'), the name given in the New Testament to small square boxes of parchment or black calf-skin, containing strips of parchment or vellum with certain texts of Scripture (Exod. xiii. 2-10, 11-17; Dent. vi. 4-9, 13-22) written on them. The phylacteries are worn on the left arm and on the head by all Jews (except Karaites) above thirteen years of age on week-day mornings during the time of prayer. This is done in accordance with their interpretation of Exod. xiii. 9-16. Some Russian and Polish Jews wear phylacteries all day; and they have at times been worn as amulets against demons. The writing of phylacteries is in the hands of privileged scribes (Soferim) only, and many and scrupulous are the ordinances which they have to follow in the execution of this task.

Phyllicite, a schistose clay-rock, containing a variable proportion of quartz in grains, together with mica, usually chlorite, and sometimes many accessory minerals. The rock is more crystalline than clay-slate, and passes into mica-schist. The surfaces of the folia in phyllice are frequently finely wrinkled.

Phylloxera (Gr. phyllon, 'a leaf,' and xeros, 'dry'), a group of insects belonging to the family (Phylloxeridae) nearly related to aphides and certain insects, and included within the sub-order Hemiptera in the order Hemiptera or Rhynchota. Two or three species occur in Europe, living like many related forms as parasites on plants. Most important is P. vastatrix, which ravages
Phylogeny

Phylo- or phylo-, "race," and -genus, a biological term applied to the evolution or genealogy of a race or tribe. It is used in contrast to "ontogeny"—the development or life-history of an individual; witness Haeckel's "biogenetic law": "Ontogeny is a recapitulation of Phylogeny." See Darwinian Theory, Embryology, Evolution, Heredity.

Physalia. See Portuguese Man-of-War.

Physalis. See Winter-Cherry.

Physeter. See Whale.

Physicians, The Royal College of, was founded by the munificence of Thomas Linnaeus (q.v.), a physician and scholar. In 1718, through the influence of Cardinal Wolsey, he obtained from Henry VIII, letters-patent granting to John Chamier, himself, and Ferdinando de Victoria, the acknowledged physicians to the king, together with Sir Henry, Sir John, Sir Francis, Robert, John, and all other men of the same body in London, to be incorporated as one body and perpetual community or college. They were permitted to hold assemblies, and to make statutes and ordinances for the government and correction of the College, and of all the same faculty in London and within 7 miles thereof, with an interdiction from practice to any individual unless previously licensed by the president and College. Linnaeus was the first president, and held the office till his death in 1524. The meetings of the College were held at his house in Knightbridge or St. James's Street, near Lincoln's Inn Fields, and which until the year 1600 continued in the possession of that body. About the time of the accession of Charles I. the College, requiring more accommodation, took a house at the bottom of Amen Corner, which was subsequently purchased by Dr. Bacon, Hamping being given by his colleagues. This was the seat of the College till 1666, when it was destroyed by the great fire of London. A new College was then built in Warwick Lane, and opened in 1674 under the presidency of Harvey's friend, Sir George Ent; and there remained until 1722, when the present edifice in Pall Mall East was opened under the presidency of Sir Henry Halford.

The reason for forming the incorporation, as set forth in the original charter, is "to check men who profess physic rather from avarice than in good faith, to the damage of credulous people," and the king (following the example of other nations) founded a college of the learned men who practise physic in London and within 7 miles, in the hope that the ignorant and rash practisers be restrained or punished. The charter further declares that no one can be admitted to the said city, or within 7 miles, without the College license, under a penalty of £5; that, in addition to the president, four censors be elected annually to have correction of physicians in London and 7 miles' circuit, and of their medicines, and to punish by fine and imprisonment; and that, the president and College be exempt from serving on juries. Four years later, in 1522-23, an act was passed confirming the charter, and enacting that "six persons before-said named as principals and firstnamed of the said commonality and fellowship shall choose to them two men of the said commonalty from henceforward to be called and cleped Elects, and that the same elects yearly choose one of them to be president of the said commonalty;" and further directing that, in case of a vacancy by death or otherwise, the surviving elects shall choose successors.

In 1540 an act was passed in which it was declared explicitly that "surgery is a part of physic, and may be practised by any of the company or fellowship of physicians—a doctrine which in later times has been totally repudiated by the 'collegians' of England, who now not admittance to their privileges a member of the Royal College of Surgeons, unless he formally resigned his surgical diploma. Other acts were passed in 1553, 1584, and 1588; the last known as the "Medical Act," providing for the granting of a new charter to the College, which was obtained in 1662. Finally, in 1669, "an Act to Amend the Medical Act" was passed, which repeals the provisions of the Act of 1522-23 as to the elects, and declares that the presidency shall in future be an annual office, open to the Fellows at large, who shall also be the elects. At the present epoch the College consists of Fellows, Members, Licentiates, and Extra-Licentiates (in 1891, 288 Fellows, 466 Members, 4037 Licentiates, and 30 Extra-Licentiates). The Fellows are elected from members of at least four years' standing, who have displayed some degree of proficiency in medicine, or in the pursuit of medical or general science or literature. The government of the College is vested in the president and Fellows only. The present Members consist of persons who have attended the College, and have been received into the Society of Fellows or Licentiates of the College; extra-licentiates who have complied with certain conditions; and of persons who have attained the age of twenty-five years, and who, with rare exceptions, must be
graduates in medicine of a recognised university or licentiates of the College, who do not dispense or supply medicine, and who, after being duly proposed, have satisfactorily satisfied the College 'touching their knowledge of medical and general science and literature.' No candidate is admissible if engaged in trade or connected with a druggist's business, or who even practises medicine in partnership with another practitioner, so long as the partnership lasts, or admits of being disused, or otherwise used, the nature and composition of any remedy they make, the use of. The members are alone eligible for the Fellowship. They have the use of the library and museum and the privilege of admission to all lectures; but they do not take any share in the government or warrant or vote at meetings. The examiners for the membership are the president and censors. The Licentiates are not members of the corporation; they have access to the museum, lectures, and reading-room, but are not allowed to take books away from the library; they may compound and dispense medicines for patients under their own care, and in their qualifications very much resemble those who have diplomas both from the College of Surgeons and the Apothecaries' Hall. They must be twenty-one years of age, and have been engaged in professional studies for four years before being admitted. The fee for admission as a Fellow is thirty guineas, exclusive of stamp-duty; the Member's fee is also thirty guineas, and the Licentiates fifteen guineas.

The following by-laws of the College should be generally known: (1) No Fellow of the College is entitled to use for professional aid all that is contained by him. This by-law does not extend to Members. (2) No Fellow, Member, or Licentiates of the College is entitled to assume the title of Doctor of Medicine unless he be a graduate in medicine of a university. (3) No Fellow or member of the College shall officiously, or under colour of a benevolent purpose, offer medical aid to, or prescribe for, any patient whom he knows to be under the care of another legally qualified medical practitioner.

The Royal College of Physicians of Edinburgh was in 1617, in an attempt to incorporate the practitioners of medicine, and raise the standard of the profession. King James I. of England looked favourably on the proposal, and granted an order for its establishment. King Charles I. also gave the matter his attention and referred it to the Privy Council, which in 1629, in a manner issued a patent in its favour: all these attempts, however, were frustrated by the religious and political dissensions of the times, and it was not until 1681 that the body became incorporated under a charter from Charles II. A new charter with many important provisions was issued in 1831.

To the Physicians belongs the honour of having suggested in 1725 the plan of an infirmary in Edinburgh for the sick poor, which has developed into the present magnificent institution. From the first the College of Physicians has gratified, to the Royal Edinburgh Asylum for the insane and the Morningside was also first suggested by them in 1791. The College, which in 1890 had over 190 Fellows, possesses a library of upwards of 30,000 volumes, a valuable and interesting museum of medical and surgical objects, and a library of objects, for the purpose of aiding the prosecution of scientific research. An important arrangement was made in 1869 between this college and the Royal College of Surgeons (q.v.) of Edinburgh, making it competent to the College to examine, in order, by a joint examination, to give the degree of Fellow, embracing medicine and surgery. In 1884 a further consolidation of the Scottish medical corporations took place, by the institution of a triple qualification, granted by the Edinburgh colleges and the Faculty of Physicians and Surgeons of Glasgow conjointly.

Physic Nut (Curcas), a genus of plants of the natural order Euphorbiaceae, whose seeds are tropical shrubs or trees, having alternate, stalked, ovoid or oblong leaves, and coryns of flowers on long stalks. The Common Physic Nut of the East Indies (C. purpurea), now also common in the West Indies and other warm parts of the world, is a small warm bush, with a milky juice. It is used for fences in many tropical countries, and serves for a purpose with being much branched and of rapid growth. The seeds are cast for use to the taste, but abound in a very acid fixed oil, which makes them powerfully emetic and purgative, or in large doses poisonous. The expressed oil, commonly called Jalopyra-oil, is used in medicine like croton-oil, although less powerful; it is also used in lamps. Other species are C. multifidus and C. lobatus.

Physic, or Physical Science (Gr. phusikos, 'natural'), comprehends in its widest sense all that is classed under the various branches of mixed or applied mathematics, natural philosophy, chemistry, and natural history, which have contributed to the whole of our knowledge regarding the material universe. In its narrower sense it is equivalent to Natural Philosophy (q.v.), which until of late years was the term more commonly used in Great Britain, and denotes all knowledge of the properties of bodies as bodies, or the science of phenomena unaccompanied by essential change in the objects; while chemistry is concerned with the composition of bodies, and the phenomena accompanied by essential change in the objects, and natural history, in its widest sense, includes all the phenomena to the animal, vegetable, and mineral world. The use (now obsolete) of the term Physic for a branch of this last—viz. the science of medicine—is not peculiar to the 'English language. The Old French usage recognised phisique in the sense of medicine; while almost all languages have used some form of the word physicus for a practitioner of the art. See SCIENCE.

Physiocratic School, a school of political economists in France headed by Quesnay and Gournay, who, in opposition to the Mercantile System (q.v.), regarded agriculture as the great source of wealth, and recommended that the state should regulate legislation accordingly. Turgot (q.v.) was the most conspicuous member. See POLITICAL ECONOMY.

Physiognomy (from a Latin shortened form of the Gr. physiognomonia), the art of judging of the character from the external appearance, especially from the countenance. The art is founded upon the belief, which has long and generally prevailed, that there is an intimate connection between the features and expression of the face and the qualities and habits of the mind; and every man is conscious of instinctively forming impressions in this way for himself with more or less confidence, and of acting upon them to a certain extent in the affairs of life. Yet the attempt to reach this conclusion by the application of certain rules, and thus to raise the art of reading the human countenance to the dignity of a science, although often made, has by many been very successful. Comparisons were instituted for this purpose between the physiognomies of human beings and of species of animals noted for the possession of peculiar qualities, as the wolf, the fox, etc. The various views were propounded by Porta (died 1615), Campanella, Cardan, Ingegnzer, and especially by Lavater (q.v.). Darwin's Expression of the Emotions in Man and Animals (1872) is regarded as the first attempt to lays a rational physiognomic system on a basis of modern scientific
Physiography, a term formerly used of a branch of minology, was adopted by Professor Huxley as a convenient name for an exposition of the principles that underlie physical geography, and including the elements of physical science. Physiography is thus understood to involve a comprehensive discussion of gravitation, heat, the composition of the crust of the earth, the movements of the sea, the phenomena of the atmosphere, and many cognate subjects, treated in this work under separate heads. See Geography.

Physiologus. See Bestiary.

Physiology (Gr. physi and logos, 'discourse upon nature') is the science which treats of the mechanism of living beings, and of the functions of their parts. It is thus the sister-science to Morphology (q.v.), in which the outer form of living creatures and the structure and arrangement of their parts are considered. Both are included under the more general term Biology (q.v.). A physiological term is Hippocrates, who applied it to a spiritual entity which he supposed to be everywhere present, and to keep the processes of the body in order. This use of the word is still kept alive in oft-repeated phrases, as when in speaking of a sick person it is recommended that the cure be left to nature. There is an Animal Physiology, of which this article will mainly treat, and a Vegetable Physiology (q.v.); also a Comparative Physiology, which, however, is still very imperfect, for the details of the life-processes have been investigated in not more than a dozen animals. Comparative physiology consists chiefly of a series of inferences as to function from comparative morphology, and these must be often erroneous. There is a still wider science, which might be called Universal Physiology. For as all the organs of the body are mutually related, so that if one be deranged all the others will be more or less affected, are there close relationships between the various creatures of the globe. Thus, to quote Semper, Animal Life (1881): 'If the American prairies were to cease to produce grass, the first result would be the extinction of the buffalo herds of buffaloes, and on their existence depends that of the surviving remnant of the ancient Indian population of America. If the various insectivorous birds of North America were exterminated, within a very few years beyond a doubt all the produce of the food districts that contain them would be destroyed. If we change the mode of life of any single animal, the change will instantly have an influence on all the other animals whose healthy existence was in any way dependent on its normal function before it was altered. The most obvious relation of this sort is that which exists between plants and animals; similar ones hold good for human beings in their relationship to other living things, and to each other. Thus we see in Political Economy, the science which treats of the laws of human activities, a department of the science of physiology. A still wider application of this science would be to the study of plants, a subject called Phycology (q.v.).

In view of the fact that the intimate relations between chemical, physical, and living processes are becoming daily more evident, it would be quite consistent that morphology should deal not only with the forms of plants and animals but also with those which the dust of the earth, the pyramid, and star, while physiology would treat of the forces and chemical processes concerned.

Knowledge of the bodily functions has been gained in three ways: (1) by observing the normal processes of life; (2) by experiments upon them; (3) by studying the effects of disease, that is, pathomorphology.

No science can advance rapidly or with certainty without experiment, and most of our precise knowledge of physiology has been gained in this way, from the time when Galen proved that the arteries during life contain blood, or when Harvey demonstrated the circulation of that blood. As an example of how we may learn from disease, we may note the discovery that the spleen produces white blood-corpuscles, following from the observation that in morbid enlargement of that organ the blood contains an increased number of these cells.

The functions of the body consist of (1) Movement, (2) Nutrition, (3) the activities associated with the Nervous System, (4) Growth and Reproduction—the latter being considered as continued growth. Movement is performed by the contraction of muscles, definitely arranged, especially with relation to the skeleton or supporting structure. Nutrition is a general term including all those processes concerned in the supply of matter and energy to the body, and the removal of waste products. It may be considered under three headings: (1) the introduction of food into the body and its carriage to the tissues; (2) the changes of this matter within the tissues; (3) the removal of waste matters from the tissues and from the body—Excretion (q.v.). The first includes (a) the eating and drinking of solid and liquid food, and the intaking of oxygen, a part of Respiration (q.v.); (b) the Digestion (q.v.) of the food; (c) its absorption into the Blood (q.v.); (d) the circulation of the blood and its associate the Lymph (q.v.), by means of which the tissues are bathed in a stream of food derived from the waste matters from them. The nervous system is the co-ordinator of all the processes of the body; it consists of the Brain, Spinal cord, Sympathetic system, and the associated Nerves and smaller Ganglia; in close connection with it are the sense-organs, the eyes, ears, nose, tongue, and general nerves of touch and temperature; the brain is the seat, or at all events the chief seat, of consciousness, and the 'organ of thought and other mental processes. The functions of the body are dealt with in separate articles; here we shall give a short account of their development in the lower animals.

Let us first consider the life of the simplest animals. Almost invisible to unaided sight, flourishing in the stagnant water of ponds, without separate organs, they are little more than tiny masses of jelly-like Protophora (q.v.). Their life seems to consist merely in the absorption of food and reproduction; possibly they possess the elements of consciousness. For movement a source of energy is required; this is found in their food—minute organisms, and organic particles dissolved in the water in which they live. These consist of substances which may be utilized by the plants which are able to utilise the energy of the sun for their growth, or remains of plants or animals which have fed upon plants (see Vegetable Physiology). Thus we see in animal
protoplasm a machinery for the transformation of potential energy into energy of motion. This machinery is constantly breaking down and being repaired, the protoplasmic matter is continually being replaced by new matter similarly combined.

But, as the protoplasm is extremely complex, the simpler substances of the food have to be combined in the correct manner and in the correct amount to produce increasing complexity until the complex living matter is formed. These combinations are supposed to be due to a ferment-like power of the protoplasm. This power it is which makes growth possible—i.e., the actual increase in animal tissue (q.v.) or plant growth (q.v.). The energy that can be extracted out of its solution is probably a process not utterly unlike, though much simpler, Growth of a crystal may seemingly be endless, but growth of a cell never proceeds beyond a certain point, when the process known as Cell-division occurs. The mass of protoplasm divides into two halves, and each half goes on to live as before. The necessity for cell-division arises partly from the conditions of the food-supply. Food is absorbed through the surface of the cell, but with growth the mass to be fed increases in a faster rate, and sooner or later division must occur at a certain stage of growth unless the cell divides. The higher animals are built up of numberless cells which have all arisen, by division, from a single cell, the ovum; but instead of becoming separated they have all kept together, jointed together, to form the animal body. As long as the cells are massed into tissues and the tissues into organs, the organs having special functions. This difference in the behaviour of the cells of different parts of the body is known as Division of Labour (q.v.). We can form some idea of its origin. Imagine a large number of cells feeding on the same food, and let the food not be able to remain loosely joined together; the outer and inner cells would live under different conditions and would assume different functions. The whole story of the evolution of life, both in the origin of individual forms and in the growth of nations, is simply the process of the division and amalgamation of labour. For just as an organism is a collection of cells, each having its own life, yet all bound together for mutual service, so is a nation a collection of individual men and women. And as the perfection of an animal is measured by the completeness of the division of labour among its cells, so is the civilisation of a nation measured by the harmony of organisation of its labour. Further, just as there have been many species of animals which have appeared, lived for a time, and then given place to higher species of animals, civilisations which have flourished for a time and then died away. Any fairly complex civilisation will serve as a type of the division of labour in the body of one of the higher animals. First there are the persons concerned in the getting of food, like the limbs and mouth of an animal. Then the food is prepared for use by other labourers; such are the digestive organs of the animal. The food has to be distributed to all members of the community by merchants and carriers; the blood and the blood-vessels perform this function. The body of the animal is kept warm by the action of the digestive organs, directed and governed, and made to act harmoniously by the statesmen of a nation; the same things are done by the senses, the brain, and the nervous system of an animal.

We have already remarked the source of all the energy of an animal lies in its food. We know that this is either burnt as it were within the tissues, used as fuel for the protoplasmic machinery, or used to keep that machinery in repair; in either case the food-stuffs have to be prepared before they can be used. Such preparation is called digestion, which consists in making the solid food-stuffs divisible. The digested food is absorbed into the blood, and all of it, except the fat, is carried directly to the liver. This organ, amongst other functions, regulates the composition of the blood; thus, it stores the sugar in its cells, and gives it out as other the tissues require. Muscular tissue is the great consumer of sugar, which is to the cells what coal is to the steam-engine. Buoyancy, warmth and most important food-stuff that requires no digestion. This is oxygen, which is needed by the protoplasm for its life, and also for the burning of fuel within the living machinery to get heat and energy of motion. The oxygen is held in the blood (q.v.) and from this oxygen a cell greedily absorbs it from the air in the lungs, and yet gives it up readily to the protoplasm of the tissues. The blood as is well known circulates round and round the body, pumped by the heart. It is a stream of food material by which each cell of the tissues is fed. For each cell is close to a capillary, which is a very thin walled blood-vessel, through which the fluid food ounces, and thus bathes the tissues. The matter which has thus passed out of the blood-vessels is collected in other vessels, and is ultimately eventually emptied into one of the great veins. The lymph stream is also the drain into which is thrown by each cell the waste products of its activity. The carbonic acid that is formed in the tissues is carried away by the blood, and escapes out coast the stream-vessels. But there is another put water is also got rid of in the same way, and some more of it is sweated out by the glands in the skin; the rest is filtered out of the blood by the kidneys. There are many other waste matters besides carbonic acid and water. These are to a general the cell body; some are taken out of the blood of other organ, being poured into the intestine, mixed with other matter, dissolved in a fluid called bile (q.v.). They are all taken out of the blood by the kidneys, and cast out of the body as urine.

This finishes our sketch of the labours of the inferior members of the cell community. The more skilled workmen are the cells of the sense-organs and the nervous system; these are described in other articles. As has been noted, their function is to inform the community of what is going on in the outside world, and to keep in harmony all the diverse labours of the various organs.

The function of Reproduction is treated in that article. The organs are the machinery of life to consider and the fact of death. The general theory of the length of life is set forth in the article on longevity. The usual view of death is that it is inherent in living matter; that there is some cause which renders the cells of the body, after a certain period of life, and after a certain number of divisions, less and less able to nourish themselves, to continue dividing, and to keep the body in repair. Recently it has been suggested by Weismann that death has been evolved by natural selection as a protective against the continuance of individuals (for no one can escape slight injuries) that would be only a burden to the species.

For Comparative Physiology, see the articles on the various functions and groups of animals.

The History of Physiology. As we have already remarked the source of all the energy of an animal lies in its food. We know that this is either burnt as it were within the tissues, used as fuel for the protoplasmic machinery, or used to keep that machinery in repair; in either case the food-stuffs have to be prepared before they can be used. Such preparation is called digestion, which consists in making the solid food-stuffs 375
and lastly, the essential constituent of the body is water: 'Water is the flesh of living things.' The last three stages, beginning with the analysis of organs into tissues, have been developed within the last hundred years. The history looked at from this point of view is enlarged upon in the article Biology; here we shall give a history of a more detailed nature. The three periods—(1) the speculative period; (2) that associated with the name of Aristotle; (3) headed by Galen, (4) by Harvey and Haller, and (5) by Müller. The first period opens with the beginning of medical science in India, China, and Egypt. The Jews were the first to establish medical practice, hygiene and dietetics. Thus came the philosophers of Greece. Matter was supposed to consist of four elements, fire, air, earth, and water. The essence of life was referred first to one and then to another of these elements by various philosophers; by Thales to water, by Anaximenes to the air, by Xenophen to the earth, by Pythagoras to fire or heat. Hippocrates, the father of medicine, about 430 B.C., was the first to pass to a purely rational spirit. Observing carefully the facts of disease, he strove to found the art of medicine upon the results of experimental observation, discarding all supernatural causes, and not to special visitations of the gods; and as already noted, he postulated a spiritual essence universally diffused; this he called Nature. Physiogam, and to this he ascribed the maintenance of things in their normal state, and their restoration if disturbed. The second period is headed by Aristotel, the father of natural history, about 350 B.C. He dissected many animals, and attempted to discover the uses of the various parts. It is difficult to estimate correctly the exact value of Aristotle's work in physiology; it must be measured more by the method of research which he initiated than by the actual results achieved. Thus, to give an example of his ideas on the subject, the heart he imagined as the seat of the 'rational soul;' the nerves he supposed to arise in the heart; of their function he was ignorant. What is perhaps more surprising is that he described the brain as an inert viscous, cold and bloodless, whose only function was to cool the heart, and not comparable in importance to the other organs of the body. Erasistratus, the grandson of Aristotle, about 300 B.C., was perhaps the first to carefully dissect the human brain. He traced the sinuses and nerves with great accuracy, and found that the complexity of the convolutions of the gray matter was greatest in man, and that they were to some extent a measure of the intelligence. The next 400 years were barren of any useful advance; the practice of medicine reached perhaps its lowest point. The literature is occupied with discussions as to the 'animal and vital spirits,' terms used before Aristotle to express the powers of living things. The animal spirits were those that ruled over those actions of living things that were supposed to be quite different from anything that takes place in the body of a living, without the vital spirit. The vital spirits were those that were concerned in those processes going on in the body which were the result of purely chemical and physical laws. We no longer discuss whether the vital spirits live in the heart and the animal in the brain, but we have not yielded to the prejudice that the vital spirits are the essential of the living world and those of inorganic matter.

About 150 A.D. Galen, a Roman, revived the sounder method of experimental inquiry; he is the leader of the third period. He perceived that mere discourses were not sufficient to give an adequate explanation as to the functions of the living, and accordingly performed many experiments upon living animals. He proved that during life the arteries contain blood and not air, as was thought to be the case up to that time, by simply opening a vessel of a living animal. He also directed much of his study to the brain and nervous system. He was the first to state definitely that the brain, spinal cord, and nerves are the organs of sensation, intelligence, and the originators and guides of properly ordered voluntary movements; and he finally refuted the doctrine of Aristotle by proving that the brain was hot and not cold, and by arguing also that if it were a mere cooler of the blood it need not be elaborately organised. He pointed out that the brain was of the same substance as the nerves, but softer, 'as it should necessarily be, inasmuch as it receives perceptions from the organs of sensation, and turns them into thoughts and imaginations, and then has to comprehend all the objects of the understanding, for what is soft is more easily changed than what is hard.' He discovered also that the nerves of sensation and of motion are distinct, and thus explained the double supply of nerves to the tongue and eyes. For centuries Galen exercised an undisputed sway over the practitioners of medicine and the students of allied philosophy.

Some centuries afterwards the so-called Arabian physiology arose. Avicenna, about the year 1000, was its first exponent, and to natural causes and to special visitations of the gods; and as already noted, he postulated a spiritual essence universally diffused; this he called Nature. Physiology, and to this he ascribed the maintenance of things in their normal state, and their restoration if disturbed. The second period is headed by Aristotle, the father of natural history, about 350 B.C. He dissected many animals, and attempted to discover the use of the various parts. It is difficult to estimate correctly the exact value of Aristotle's work in physiology; it must be measured more by the method of research which he initiated than by the actual results achieved. Thus, to give an example of his ideas on the subject, the heart he imagined as the seat of the 'rational soul;' the nerves he supposed to arise in the heart; of their function he was ignorant. What is perhaps more surprising is that he described the brain as an inert viscous, cold and bloodless, whose only function was to cool the heart, and not comparable in importance to the other organs of the body. Erasistratus, the grandson of Aristotle, about 300 B.C., was perhaps the first to carefully dissect the human brain. He traced the sinuses and nerves with great accuracy, and found that the complexity of the convolutions of the gray matter was greatest in man, and that they were to some extent a measure of the intelligence. The next 400 years were barren of any useful advance; the practice of medicine reached perhaps its lowest point. The literature is occupied with discussions as to the 'animal and vital spirits,' terms used before Aristotle to express the powers of living things. The animal spirits were those that ruled over those actions of living things that were supposed to be quite different from anything that takes place in the body of a living, without the vital spirit. The vital spirits were those that were concerned in those processes going on in the body which were the result of purely chemical and physical laws. We no longer discuss whether the vital spirits live in the heart and the animal in the brain, but we have not yielded to the prejudice that the vital spirits are the essential of the living world and those of inorganic matter.

Physiology, and to this he ascribed the maintenance of things in their normal state, and their restoration if disturbed. The second period is headed by Aristotle, the father of natural history, about 350 B.C. He dissected many animals, and attempted to discover the use of the various parts. It is difficult to estimate correctly the exact value of Aristotle's work in physiology; it must be measured more by the method of research which he initiated than by the actual results achieved. Thus, to give an example of his ideas on the subject, the heart he imagined as the seat of the 'rational soul;' the nerves he supposed to arise in the heart; of their function he was ignorant. What is perhaps more surprising is that he described the brain as an inert viscous, cold and bloodless, whose only function was to cool the heart, and not comparable in importance to the other organs of the body. Erasistratus, the grandson of Aristotle, about 300 B.C., was perhaps the first to carefully dissect the human brain. He traced the sinuses and nerves with great accuracy, and found that the complexity of the convolutions of the gray matter was greatest in man, and that they were to some extent a measure of the intelligence. The next 400 years were barren of any useful advance; the practice of medicine reached perhaps its lowest point. The literature is occupied with discussions as to the 'animal and vital spirits,' terms used before Aristotle to express the powers of living things. The animal spirits were those that ruled over those actions of living things that were supposed to be quite different from anything that takes place in the body of a living, without the vital spirit. The vital spirits were those that were concerned in those processes going on in the body which were the result of purely chemical and physical laws. We no longer discuss whether the vital spirits live in the heart and the animal in the brain, but we have not yielded to the prejudice that the vital spirits are the essential of the living world and those of inorganic matter.

About 150 A.D. Galen, a Roman, revived the sounder method of experimental inquiry; he is the leader of the third period. He perceived that mere discourses were not sufficient to give an adequate explanation as to the functions of the living, and accordingly performed many experiments upon living animals. He proved that during life the arteries contain blood and not air, as was thought to be
accecptable by Darwin's work, is the great harmoniser of all science.

This history of physiology may be shortly summarised as follows. Even to early inquirers it was obvious that many of the life-processes of animals are the result of the action of a set of machines, which we know, are supposed to be, by a comprehending action of the 'vital spirits.' These machines were called organs, and the work performed was spoken of as their functions. The whole body was conceived of as made up of various organs, and the labours of physiologists were directed towards discovering the functions, a work which to this day is incomplete. This may be called the first phase of physiological philosophy; it lasted until the promulgation of the cell-theory and the rapidly following discovery of protoplasm. The idea of protoplasm is to natural science of nearly as much importance as the doctrines of the conservation of matter and energy are in chemistry and physics. The chief labours of physiologists for a very long time will be directed towards attaining exact conceptions of the nature of this protoplasm in terms of chemistry and physics. The old question of animal and vegetable, as to whether it is necessary, we are not able to say whether there is any abrupt distinction between ordinary matter and that which is called living matter, and which forms the physical basis of life. Is it merely that living matter is more complex and unstable than ordinary matter, and further that it is sensitive to external impulses in the form of ethereal and molecular vibrations; or is there some special vital force at work? If we fully understand the first theory we shall probably believe that there is no such vital force. At any rate, we are left to its discovery in determining how far the objective phenomena of life are explicable in terms of ordinary chemical and physical laws. When we find any activity of living matter which we can be certain cannot be so explained, then, and not till then, may we postulate a vital force. Supposing that a discovery ever to be made, it is necessary to observe that it will merely widen our chemistry and physics. The discussion of the subjective consciousness of life is an entirely separate one. Ordinary philosophy postulates two entities, matter and spirit; Materialism holds that the matter when it reaches a certain stage of complexity becomes conscious; Monism, which is becoming the fashionable scientific creed, teaches that matter in motion and consciousness are the two sides—one seen from without, the other felt from within—of a single entity.

We may utilise directly, as Foster's statement, of the present problems of physiology. He speaks of them as threefold. (1) On the one hand, we have to search the laws according to which the complex unstable food is transmuted into the still more complex and still more unstable living flesh, and the laws accounting to which the living substance breaks down into the simple, stable, waste products, void, or nearly void, of energy. (2) On the other hand, we have to determine the laws according to which the vibrations of the nervous substance are transferred to the viscera; and then the laws according to which these vibrations pass to and fro in the body, acting and reacting upon each other, and the laws according to which they finally break up and are lost, either in those larger swings of muscular contraction or in some other way. (3) And lastly, we have to examine the abstruser problems of how these neural vibrations, often mysteriously attended with changes of consciousness, as well as the less subtle vibrations of the contracting muscles, are wrought out of the explosive chemical decompositions of the nervous substance; i.e. how the energy of chemical action is transmuted into, and serves as the supply of that vital energy which appears as movement, feeling, thought.'

Phytelephas. See Ivy (Vegetable).

Piacenza, a city of Northern Italy, on the right bank of the Po, a little below its confluence with the Trebbia, by rail 43 miles SE. of Milan and 35 N.W. of Parma. Situated at the end of the Via Emilia and at the last convenient crossing-place eastwards on the Po, it has always been an important city of commerce and manufacture, since its foundation (as Placentia) by the Romans in 210 B.C. It is defended with bastioned walls and an outer ring of forts. Its streets are broad and regular, but many of them unfrequented and grass-grown. The cathedral, in the Lombard-Romanesque style (1122), is famed for its tower, which is 225 feet high, and paintings by L. Carracci, Guercino, and others. The church of Sunt' Antonio, the original cathedral, was founded in 324, but has been several times rebuilt. The church of Santa Maria della Campagna is adorned with fine frescoes by Pordenone, and in it San Sisto that Raphael painted the celebrated Sistine Madonna, sold in 1754 by the monks to Frederick Augustus of Saxony. Among the other buildings are the Palazzo Farnese (1558), once a sumptuous edifice, but since 1860 in use as barracks; the communal palace (1821). Its lower story built of marble and the upper of brick; the palace of justice, and others. A couple of miles to the east of the city is the theological seminary founded by Cardinal Alberoni. The municipal library contains 120,000 volumes. The town is adorned with colossal bronze equestrian statues of Alessandro and Rancuccio Farnese. Manufactures of silks, cottons, pottery, hats, &c, are carried on. The more notable facts in the history of Piacenza have been its capture by the Gauls in 290 and by Totila in 546, the meeting here of two church councils in 1095 and 1132, its active zeal as a member of the Lombard League in the 12th century, the sacking of it by Francesco Sforza in 1447, and its union with Parma (q.v.). Pop. (1897) 35,590.—The province has an area of 950 square miles, a pop. 290,000.

Pin Mater. See Brain.

Piana dei Greci, a town of Sicily, 10 miles S.W. of Palermo. It was the chief Albanian colony in Sicily in the 15th century.

Pianoforte (Ital. piano, 'soft,' and forte, 'loud'), a stringed musical instrument, played by keys, developed out of the clavicord and Harpsichord (q.v.), from which the pianoforte differs principally by the introduction of hammers, to pluck the strings in vibration, connected with the keys by a mechanism that enables the player to modify at will the intensity of the sounds; whence the name of the instrument. The invention of the pianoforte must be accredited to Bartolomeo Cristofori, a native of Pianu, who produced his instrument in 1714. Other claimants to the honour are a German harpsichordist, Johannes Schroeter, and Marius, a French harpsichordist.
chord maker. The first pianoforte seen in England was the instrument patented by Pianoforte by an English monk there. In Germany the invention met with more rapid encouragement and development than in Italy. The Silbermanns in Straßburg and Stein of Augsburg improved the discoveries of their countryman Schröter, and many Germans are found to maintain that the pianoforte is an independent invention indigenous to the Fatherland. In England the manufacture of the instrument was at first chiefly in the hands of foreigners, principally Italians. Italian pianoforte-makers opened many shops, but the English makers ultimately rivalled and surpassed the Italians. English pianoforte has been brought to its present state of perfection by Broadwood, Collard, Brinsmead, and others. Erard made many improvements in France; Germany has long been famous for its pianos, including those of Bechstein; and the American pianos of Steinway and Chickering are well known.

The commencement of the early pianoforte was, like that of the harpsichord, four to five octaves, and has gradually increased to seven octaves, or occasionally more. The most natural of the various forms which the instrument assumes is that of the grand pianoforte, which is derived from the harpsichord, with the strings placed horizontally, and parallel to the keys. The strings are stretched across a compound frame of wood and metal, composed of bars, rods, and strengtheners of various kinds—appliances necessary to resist the enormous tension. This framework includes a wooden sound-board. The mechanism by which hammers are connected with the keys is called the action of the instrument. In the earliest pianofortes the hammer was raised from below by a button attached to an upright wire fixed on the back-end of the key. The impulse given to the hammer caused it to strike the string, after which it immediately fell back on the button, leaving the string free to vibrate. This was called the single action. As the hammer, when resting on the button with the key pressed down, was thus necessarily at a little distance from the string, the effectual working of this action required that a certain impetus should be communicated to the hammer to enable it to touch the string. Hence it was impossible to play very softly, and it was found that, if the hammer was adjusted so as to be too close to the string when resting on the button, it was impossible to leave the string till after the blow had been given, thereby deadening the sound. This defect was remedied by a jointed upright piece called the hopper, attached to the back-end of the key, in place of the wire and button. When the key was pressed down the hopper, engaging in a notch in the lower side of the hammer, lifted it so close to the hammer that the lightest possible pressure caused it to strike; and at this moment, when the key was still pressed down, the jointed part of the hopper, coming in contact with a fixed button as it moved upwards, and the hammer fell clear away from the string. To prevent the hammer from rebounding on the string a projection called the check was fixed on the end of the key, which caught the edge of the hammer as it fell, and let the hammer fall clear away from the string. A necessary part of the action is the damper, which limits the duration of each particular note, so as to cause it to cease to sound as soon as the pressure is removed from the key. It consists of a piece of leather resting on the top of the string and connected with a part of the action by a vertical wire. When any key is pressed down its damper is raised off the string, so as to allow the sound produced to be clear and open; but immediately on the finger being lifted off the key the damper-wire falls, and the damper again presses on the string, muffling and stopping the vibration. The pianoforte possesses two pedals, the loud and the soft. By the former the dampers are raised, the result of which is to prolong the sound of the notes and cause them to run into one another. The employment of this pedal is designated by the word ped. written below the treble staff, while an asterisk is used to denote its cessation. The soft pedal, on the contrary, diminishes the sound, by removing a string from the impact of each of the hammers. Its employment in the music is denoted by the words una corda. One further frequent and important addition to the action may be alluded to. In the mechanism above described the key must rise to its position of rest before the hopper will again engage in the notch of the hammer for another stroke; hence a note cannot be repeated until time has been allowed for the full rise of the key. The repetition action is a contrivance, varying in different instruments, for getting rid of this defect by holding up the hammer at a certain height while the key is returning.

Great detail of the parts of the different makers. Some are more complicated than others; but in all are to be found the same essential parts, only modified in shape and arrangement. The subjoined figure represents one of the simplest grand pianoforte actions now in use. A is the key; B, the lever which raises the hammer; C, the hammer; D, the string; and E, the damper; F is the button which catches the lever after it has struck the hammer; G, the check; H, the damper pedal-lifter; I, the spring; and K, K, are rails and sockets. Formerly the strings of the pianoforte were all of thin wire; now the bass-strings are very thick, and coated with a fine coil of copper wire; and the thickness, strength, and tension of the strings all diminish from the lower to the upper notes. The grand pianoforte has three strings to each of the upper and middle notes, and now, generally, only two to the lower notes, and one to the lowest octave. When the soft pedal is pressed down the hammers are shifted sideways, so as to strike only two strings instead of three, or one string instead of two.

Besides the full or concert grand, there is the semi-grand or square piano with curtained key-board, now superseded by the cottage piano, of which the upright grand is merely a larger form. In the cottage piano the strings run vertically from top to bottom, and the formation of the sound in form necessitates alterations in the details of the action, but the general principle is the same. The pianette, a small form of the cottage, has also come into great favour. The pianoforte has attained a widespread popularity, owing chiefly to the fact that it can render harmonious though the violin is proving a serious rival to it in domestic circles. In England the manufacturers who have for some time past enjoyed the highest repute are Messrs Broadwood, Brinsmead, and Kirkman. Messrs Brinsmead have also introduced a patented pianoforte called the Sostenente, in which, by a number of hammers playing consecutively on a string, and so closely as to cause no interruption in the sound, any note may be sustained (whence the name sostenente) for an indefinite length of time,
and the same solemn and majestic effect may be produced upon the pianoforte which has heretofore been confined exclusively to the organ. The latest development to which the pianoforte has been carried is that introduced by an Austrian of the name of Janko. A great number of his pianos are now being made. Recognising the complete change which has passed over pianoforte music since the days when Mozart and Haydn wrote and, so to speak, created the literature of the instrument, Herr Janko has endeavoured to adapt the piano to the long stretches, chords, and difficult arpeggios which are the characteristics of modern playing, and were utterly unknown, or rather unemployed, in the days of the classical writers. Accordingly, he constructs his pianos with six keyboards, which rise in tiers above one another in the manner of an organ. The notes are so grasped that tenths and twelfths can be easily spanned by reaching a finger to a keyboard above or below that on which the hand is travelling; and, with a sweep of the wrist, which would scarcely cover more than two octaves on the old keyboard, an arpeggio can be executed through the whole compass of the piano's notes. The objections to Herr Janko's improvement come mainly not from the public but from the music publishers; for, while to a beginner on the instrument it is immaterial what system of fingering be adopted, publishers are naturally jealous of a new pianoforte which would render useless and compel complete remodelling not only of all the fingering, but perhaps of the stuff.

Music for the pianoforte is written in two staves, and with the treble and bass clefs. Many of the most eminent musicians have devoted themselves to composing for the pianoforte, and some composers of note, as Hummel, Chopin, Thalberg, and Heller, have almost entirely confined themselves to that instrument. Amongst the greatest modern pianists have been Madame Schumann, Liszt, and Rubinstein. See Rimbaud, The Pianoforte (1860); Grove's Dictionary of Music and Musicians; and the histories of music and of musical instruments (such as Hopkins's Musical Instruments, 1887).

Pianists, or ' Fathers of the Pian Schools,' are religious congregation for the education of the poor, founded at Rome in 1617 by a Spanish priest, Joseph of Calasanza, and continued in 1621 by Gregory XVI. They were chiefly active in Poland and Austria.

Piasaya. See FIBROUS SUBSTANCES.

Piastra (Gr. and Lat. emplastron, ' a plastron,' in the Romance languages, anything spread out or flattened, ' a plate,' ' a coin '), an old Spanish silver coin worth about 4s. It was divided into 8 silver reals, and hence was termed a piece of eight, the name invariably applied to it on the Spanish Main (see DOLLAR). The Italian piastre, or svasta, was an imitation of the Spanish coin, and was nearly equal to it in value. The Turkish piastre is a silver coin worth about 2d. in English reckoning and 4 cents in United States currency. Usually 25 piastres = £1 sterling and 100 = 20 francs. The lira contains 100 piastres. Pieces of 1, 2, 5, 10, and 20 piastres are struck in silver.

Platigorsk, a town in Russian Caucasia, at the southern foot of Mount Beshtan (4387 feet), facing Mount Elbrus, and at the base of the Caucasus Mountains, and 324 miles by rail NW. of Vladikavkaz, is celebrated for its sulphur-springs. Rising from 83.7° to 117.5° F., in temperature, they are useful for abdominal and rheumatic affections. Pop. 13,660.

Platres, a town of Moldavia, 60 miles W. by S. of Jassy, romantically situated on the Dristiza, at the (eastern) foot of the Carpathians, has a trade in timber and a pop. of 13,800.

Piazza (more fully Piazza Armerina), an episcopal town of Sicily, 16 miles SE. of Caltanissetta. Pop. 17,038.

Piazzini, Giuseppe, Italian astronomer, was born at Ponte in the Valtelline, July 16, 1746, and entered the order of the Theatins at Milan in 1764. After holding professorial chairs of Philosophy, Mathematics, and Theology, at Padua, Ravenna, and Rome, he was appointed in 1789 to the chair of Mathematics in Palermo; and there, with the aid of government, he established an observatory in 1789. The first task he set himself was to make a chart of the stars, published in 1803, and again extended in 1814. On the night of the 1st January 1801 he discovered a new planet, the first of the group of planetoids between Mars and Jupiter, and named it Ceres. He died, 22d July 1826, at Naples.

Pibroch (Gaelic, Piobaireachd, ' a pipe tune '), a form of bagpipe music, generally of a warlike character, including marches, dirges, &c. According to Sir Walter Scott, connoisseurs in pipe-music affect to discover in a well-composed pibroch the imitative sounds of march, conflict, flight, pursuit, and all the current of a heady fight. The rhythm is very irregular and difficult for a stranger to follow, but when played by a good piper it has a very powerful effect. The earliest mention of the military music of the bagpipe is in 1594 at the battle of Glenlivet, but the various pibrochs belonging to the different clans are mostly of modern composition.

See Macdonald, Ancient Martial Music of Scotland (about 1805); Mackay, Collection of Ancient Piobaireachd, or Highland Pipe Music (1838); and Ossian's Collection of Piobaireachd.

Picardy (Picardie), an ancient province in the north of France, was bounded on the W. by the English Channel, and on the E. by Champagne. The capital of this province was Amiens. The territory now forms the department of Somme, and portions of the departments of Aisne and Pas-de-Calais.

Picaresque. See NovELS.

Pleauyme, a name derived from the Carib language, and used in Louisiana for a small coin worth 6½ cents, and current in the United States before 1837, and known in different states in various names (fourpence, lippence, lip, sixpence, &c.).

Piccolo. See FlUTE.

Piccolo'mini, an old and distinguished family of Italy, settled at Sienna, who subsequently obtained possession of the duchy of Amalfi. It produced numerous celebrated literati and warriors, one pope (see PIUS II.), and several cardinals. One of the most illustrious members of this family was Ottavio, Duke of Amalfi, born in 1599. He entered the Spanish military service, and being
sent to aid the Emperor Ferdinand II., fought against the Bohemians at the battle of the Weissemburg (1620), then in the Netherlands, and after that in Wallenstein's army at the Lützen (1632). He was one of the chief agents in effecting the fall of the all-powerful general, by betraying the secrets of his plans. He then began to Distinguish himself in the battle of Nördlingen (1634). In the following season he was sent to aid the Spanish in the Netherlands, and speedily drove out the French, but had not much success against the Dutch. He was with the imperial emperor in 1643 to see the Swedes, who, under Baner, were threatening the hereditary possessions of Austria. This purpose he accomplished; but, though he was successful against these northern invaders in the Palatinate, he was worsted in Silesia by Torstenso. Returning to the Spanish service in 1643, he was sent again to the Netherlands to take the command of the Spanish troops. But his success was not nearly so decisive as before, the prestige of the Spanish infantry having been destroyed by Condé at Rocroi (1643). After the signing of the peace of Münster (1648) Piccolomini was created a field-marshal by the emperor, and was sent as plenipotentiary to the Congress of Nuremberg (1649). He died at Vienna, 10th August 1656, leaving no children; his son Max, who figures in Schiller's Wallenstein, is only a poetical fiction.

Pic du Midi, a summit of the Pyrenees, 9466 feet high, in the south-east corner of the French department of Basses-Pyrénées.

Piccolomini, CHARLES, French general, was born a labourer's son at Arbois in Jura, 16th February 1761, and was educated by the Minorite friars at Arbois and at the college of Brienne. He enlisted into an artillery regiment in 1783, and showed such capacity and courage on the Rhine in the fiery service of the young republic that by 1793 he was a general of division. In October of that year he was given supreme command on the Rhine, and in conjunction with Hoche and his army of the Moselle he drove back the Austrians, relieved Landau, and overran the Palatinate. Next year he continued his career of triumph in the Netherlands, and showed in three campaigns within one year consummate generalship and a fortunate audacity worthy of the great Napoleon. After by swift movements defeating the Austrians in detail, he broke their forces at Fleunrs, June 27, 1794, and, continuing the struggle into the winter, crossed the Meuse and the Waal on the ice, entered Amsterdam, and 20, 1795, and soon occupied the whole of Holland. During this campaign occurred the famous capture by the French hussars of the Dutch ships frozen in the Helder. Recalled to Paris by the Thermidoriens, the "Sauveur de la Patrie" cursed an insurrection of the fanatiques at Paris and was removed to the Bastille and took Mannheim. But at the height of his fame he turned traitor, and sold himself for vast promises to the Bourbons. With deliberate treachery he remained inactive before the enemy, and allowed Jourdan to be defeated. The Directory becoming suspicious superseded him by Moreau, and Piccolomini retired to Arbois. In 1797 he took his place, first as member, next as president, of the council of Five Hundred, and continued his Bourbon intrigues, but on the 18th Fructidor (4th September) he was arrested and deported to Cayenne. Escaping in the June of 1800, when he made his way to London, was attached to the Austro-Russian army in 1799, and thereafter lived in Germany and England until the formation of the Bourbon conspiracy of Georges Colonial (q.v.) for the assassination of the First Consul. The pair reached Paris secretly, but found it impossible to gain over Morean. They were soon betrayed to the police, and Piccolomini was seized in bed and carried to the Temple, February 28, 1804. Here, on the morning of the 6th April, it was found that he had anticipated justice, and ended his dishonoured life with a sword. He must be credited that he had justly forfeited his life to his country's laws, and there is no justification for the royalist slander that he was made away with by Napoleon.

See the Lives by Gasnier (1814), Pierret (1826), VouZiers (1758); also the Mémoires by Montsallier (1804).

Picchiago. See Chlamyphores.

Picchina (belling mountain), the most populous province (2,205,000 in 1896) of Ecuador, embraces the Quito plateau and its slopes. Area, 5300 sq. m. The soil is fertile in the west. The province takes its name from the active volcano of Picchina, 8 miles N.W. of Quito, the chief town, it has five peaks, two of which (15,018 feet) Mr Whymper ascended in 1880. The enormous crater, nearly a mile across at the top and perhaps 1500 feet in diameter at the bottom (which is 2500 feet below), is said to be the deepest in the world.

Piclier. KAROLINE, novelist, was born 7th September 1793, at Vienna, her maiden name being Greiner; and between 1800 and her death, 9th July, 1843, wrote several novels and a novel and collected a edition of 60 volumes, of which the most notable are Agathokles (1808), Frankenuerde (1818), and Die Belagerung Wien (1824). Her autobiographical Denkwürdigkeiten (1844) fill 4 vols.

Pickering. See Pike.

Pickering, a market-town in the North Riding of Yorkshire, 32 miles N.N.E. of York. It has a fine ruined castle, which was Richard II.'s first prison, and was dismantled by the Roundheads, and an interesting parish church. Pop. (1881) 3931; (1891) 3067.

Pickles, a term generally applied to vegetables preserved in vinegar, with or without spices; though pickled applies to animal food preserved in salt (see Preserved Provisions). The vegetables most pickled in Britain are cabbage, cauliflower, gherkins or young cucumbers, French beans, onions and eschalots, walnuts, mushrooms, and mastur- bunmus. Piccalilli or Indian pickle is made of lemons or cauliflower, mustard, and flower of mustard. For the methods of preparing pickles reference must be made to a cookery-book. Capers (q.v.) are imported; also olives preserved in brine and in vinegar, and several preparations of the mango fruit. The food value of pickles as a con- diment is touched on at Diet, Vol. III. p. 869; and for adulterated pickles, see Adulteration.

Pico. See Azores.

Pico della Mirandola, one of the most curious figures in the history of the Renaissance, was born in 1463, and was the son of Francesco Pico, Count of Mirandola, and Concordia in the Modenese. He was a wonderfully precocious boy, and in his youth he visited the chief universities of Italy and France. In 1480 he issued a challenge to all comers to engage him in critical discussion at Rome, but the debate was forbidden by the pope on the score of the heretical tendency of certain of the nine hundred theses which Pico had offered to maintain. An Apologia which he issued in his defence was considered scandalous until Alexander III. In 1493 absolved him of the charge of heresy. He spent much of his life in travelling, and became known as a generous benefactor of the poor. He was an intimate friend of Politian and Lorenzo de Medici. He died of fever in 1494, and Savonarola, who had been anxious to enrol him among the Friars Preachers, vowed him
after death in the habit of the order. Mirandola was the last of the schoolmen. He endeavoured to reconcile the Catholic theology with medieval philosophy, and his works are a bewildering compound of mysticism, scholasticism, and recondite knowledge. He interpreted the Mosaic text by the Cabalistic and Pythagorean as well as to the Apothecary; he exhibited, along with a childlike credulity, a argumentative ingenuity worthy of the subtlest schoolman. He was a humanist as well as a theologian, and was the author of various Latin epistles and elegies and of a series of florid Italian sonnets. His writings are of little value, but the magic of his personality survives. A theologian and an erotic poet, a philantropist, a scholar, and a traveller, an adherent at once of Duns Scottus and of Politian, he was one of the most chivalrous, generous, and versatile of men; his character is as engaging as it is curious and cosmopolitan.

See G. P. della Mirandola, his life by his nephew (trans. by Sir Thomas More; Nutt, Lond. 1890), and Pater's Studies in the Renaissance.

Picotee. See Carnation.

Picquet. See Piquet.

Pierce Acid (Trinitrophenol), C₆H₂(NO₂)₃OH. This substance appears in the form of pale yellow crystals, obtained by the action of nitric acid on phenolsulphonic acid. Equal parts of phenol and concentrated sulphuric acid are mixed together, and placed in a suitable vessel, which is heated till the mixture reaches 212° F. (100° C.). Nitric acid of the specific gravity 1.3 is then added. On cooling, a crystalline mass is produced which is filtered and drained. A washing with cold water follows, and then the picric acid is further purified by recrystallising it from water containing a small proportion (0'1 per cent.) of sulphuric acid. Picric acid is easily soluble in hot, but only slightly in cold water. It is also soluble in alcohol and ether. Its taste is intensely bitter, and its toxicological power is very great, the solutions of it having a strong yellow colour (see Dyeing, Vol. IV, p. 141). It has been much used for dyeing silk, wool, and leather. As it does not adhere by itself to these fibres, it serves for a test to distinguish cotton from wool or silk. The presence of cotton in a mixed fabric can therefore be detected by steeping it in a hot solution of the acid, and afterwards washing it. Then, with the aid of a microscope, the difference between the wool or silk, both of which retain the dye, and the cotton, which does not, will be made clear. The salts of picric acid are a very important ingredient in explosives (see Melinite, Gun-Cotton, Shell). It was formerly called Carbazotic Acid.

Picrite, one of the peridotites or olivine rocks. It is usually olivine, but the other principal minerals are augite and plagioclase. Magnebite or hibonite, or both are generally present. Biotite occurs not infrequently, and apatite occasionally. The rock is often more or less altered into serpentine.

Picts. ADOLPHI (1799-1875), a native of Geneva, and a writer on the Celts and the primitive Aryans. To the same Genevese family belong Marcus Auguste Picquet (1752-1825), physician; François Jules Picquet (1800-72), zoologist and palaeontologist; and Raoul Picquet, chemist and physiologist, known in connection with the invention of oxygen.

Picton, SIR THOMAS, British general, was born in August 1758, at Poyston in Pembrokeshire, entered the army as ensign in the 12th Foot in 1772, and two years later joined his regiment at Gibraltar. In 1794 he went out to the West Indies, and was given a command under Sir John Vaughan. He took part in the conquest of several islands of the West Indies, including Trinidad, and was appointed (1797) governor of one of the islands. Shortly afterwards he was raised to the rank of general. In 1803 he was superseded, but immediately after appointed governor of Tobago. He found it necessary, however, to return to England, to take his trial on a charge of forgery permitted, under the old Spanish laws, a female prisoner to be flogged. He was found guilty of sanctioning unlawful torture; but on appeal he was in a new trial acquitted. He saw active service again in the Walcheren expedition (1809), and was made governor of Flushing after its capture by the English. Early in the following year he was summoned to Spain, and put in command of the ' Fighting Division,' and with it rendered brilliant service at Buena, during the subsequent expulsion of the French from Portugal, at Fuentes de Onoro, at thepasses of Ciudad and Pintido, and in Portugal, and in the battles of the Pyrenees, at Orthez and before Toulouse. Napoleon's escape from Elba once more called Picton into the field; he fought at Quatre Bras and was wounded, but kept the fact hidden that he might not miss the great day he saw coming. He fell heavily in the battle of the charge at Waterloo, 18th June 1815. See Memoirs of Sir T. Picton, by H. B. Robinson (2 vols. 1835).

Picton, a port of entry on the north coast of Nova Scotia, on a large and sheltered harbour, 85 (by rail 114) miles N.N.E. of Halifax. The town contains several mills and factories, and coal, mined in the vicinity, is exported. Pop. (1891) 2999.

Picts. This is the name by which, for five and a half centuries (296-844 A.D.), the people that inhabited eastern Scotland from the Forth to the Pentland Firth were known. In the Irish chronicles they are generally styled Picti, Pictiones, Pictores, or Piccardi— all forms of the same root; but sometimes the native Gaelic name of Cruithing is applied to them, and their country is called Cruithin-tuath, the equivalent of Latin Pictavia and Old Norse Pictah, which is the name of the Pentland Firth. There were Cruithin or Cruithing also in Ireland—never, however, called Picti. They formed the petty kingdom of Dál-ariain (County Down and part of Antrim) and bordered on the Irish Dalriada; and the state of both these provinces was contemporaneous with the whole extent of Pictish rule, much confusion is thereby caused as to what refers to Scotch and what to Irish Cruithing in the annals. Other Irish Cruithning appear sporadically, not to say enigmatically, in Moot and in Roscommon. There does not seem to have been any difference in language and customs between these Irish Cruithing and the rest of the people of Ireland, at least in historic times. They were probably early invaders from Britain belonging to the Picts.

The Picts are mentioned in connection with the campaigns of Constantius Chlorus in Britain in 296 and 306. Emmenius, his panegyrist, speaks of 'Caledonum aliorumque Pictorum silvas et paludes' (the Caledonians and other Picts), which he signifies the name of the forefathers of the northern people. Caledonia is the name given by Tacitus to Scotland north of the Firths of Forth and Clyde, and he describes the Caledonians as a noble race of barbarians, who fight in chariots as well as on foot, with long swords and short shields, and whose fair red hair and large limbs argued a German origin. Ptolomy (120) places fourteen tribes in Tacitus' Caledonia, inclusive of the Caledonians
themselves, and the more easterly ten of these may be claimed as Picts. So troublesome were these northern tribes to the Roman province that in 209 the commander of Britain, who was said vainly attempted their subjugation. The contemporary historians mention only two tribes north of the Forth and Clyde wall—the Maccate and the Caledonii—andTacitus' noble barbarians appear in their pages but squallid savages, having no cities, knowing no agriculture, possessing wives in common, and tattooing their bodies with pictures of all kinds, to show which 'they wear no clothing,' says Herodian. Yet they have chariots and weapons as described by Tacitus, with dicker and peculiarly knobbled spear. One hundred years later the Caledonians and other Picts, as already said, are encountered by Constantius, and still fifty years later they are harassing the Roman province (300) now in company with the Scots, who are first mentioned at this date, and who appear as great sea-wanderers, starting from Ireland and Scotland both, it would seem, and attacking the whole seaboard of the province, especially Wales. The Picts and Scots are helped in this 'continual vexing' of the Britons by the Saxons and Aetecotti. The Picts are represented at this time as divided into two nations called Dianili and Vercinienses, or rather Vercinienses, to accept Professor Rylai's happy emendation of Ammianus' text, for this latter form may be identified with the historic Fortrem (Strathern and Menteith). Theodosius the elior in 389 subdued these northern foes and restored the district between the walls to Roman Britain, and the usurper Maximus signalised his assumption of power in 383 by an energetic campaign against the Picts and Scots. During the next quarter of a century the Romans were losing their hold on Britain, and their northern foes pressed on the province with great persistence. First the northern wall was rebuilt, then abandoned; and hostile the southern wall was repaired by the last legion sent. In vain did the brave Stilicho gaze on the 'figures fading on the dying Pict,' as Claudian says, for they burst on the Britons. Britain with more force than ever, in the reign of the saxons against the Picts and Scots made the last state of the Britons worse than their first.

At this point the light of Roman history is withdrawn from us, and we have to depend on vague references in native writers. Gildas of Wessex, in his 'Wwards of the Wicked and the Good' (794), on Beda (781), on Nennius (9th century), and on the Irish and other annalists of the middle ages, the best of whom is Tinternach (1085). There is a Pictish Chronicle, perhaps composed in the 10th century, but preserved only in a MS. four hundred years later in date. Gildas describes the Picts and Scots as 'differing somewhat in manners,' and 'surrounding their villainous faces in bushy hair rather than clothing' their lower limbs. Bede points out that the Picts are divided into a southern and a northern division by the Grampian hills. They were converted to Christianity by St Ninian (circa 400), and the northern Picts over a century and a half later by St Columba. Bede also notes and mythically explains the system of succession among the Picts, whereby the reigning monarch was succeeded by his eldest son, but if his eldest son died before the age of twenty, his brother's son or his eldest daughter from his sister's son, descent being counted through the females. This curious rule is amply confirmed by the Pictish list of kings. Scotland in Bede's time, and for more than a century previously, was divided among four nations: the Saxons and Britons were south of the Grampian hills, the Picts east of Drumallan, and the Scots to the west with Dalriada or Argyllshire as their head centre. The annals say little of the Isles and north-west coast, whether they were held by Scots or Picts, though subsequent history makes it clear that both succeeded for a long period. The invaders of Canun in 501 were but the last of many Scotic invaders and colonisers. That the four nations of Bede's day spoke four different languages is clear from his oft-repeated statement to that effect, and his handing down a word in this Pictish tongue (parfain) by the name of Columba. Ammianus, and to employ an interpreter twice in describing the Picts, while Corunc of Cashel mentions a word (cartit) belonging to the bertha eruithech or Pictish language.

In the ninth year of the reign of Brude MacMicheal, the year 653, Columba set out to attempt to convert the Picts. Brude had his royal residence near Inverness, and was 'a most powerful king,' Bede says, for he represents him as granting Lona to Columba, though Tignernach says that Connal of Dalriada made the gift. But the Picts were carrying on war among the Isles at the time, as the life of St Columba shows, and Brude had hostages from the king of the Orkneys. Brude's successor, Gartnaith, seems to have fixed his capital at Alnethy, the church of which he founded. The Picts were subjugated by Oswald, King of Northumbria, and his tributary, soon after, Reubin in 654. Thus the Picts remained under the Anglian yoke for thirty years; but Brude, son of Bile, asserted his rule among the northern Picts, and meeting the Anglian king Egfrid at Dunsinane in 685 defeated and slew him, and thus ended the Anglian rule over the Picts. About 710 Nation or Nectan, son of Derick, King of the Picts, and as Bede tells us, he conformed under Anglica influence to the Roman Church in regard to the celebration of Easter, going indeed so far as to expel recalcitrant Columban clerics across Drumallan. Following a custom not infrequent at the time, Nectan resigned his throne and became a cleric. A fierce struggle ensued for the throne, during which Nectan emerged from his monastery, but eventually Angus, son of Fergus, petty king of Fortrem, crushed all his rivals and reigned for thirty years, when this 'v�reme tyrant' died 761. His brother Brude died king of Fortrem in 763, for evidently Angus' monarchy had collapsed and the provincial kings again came to the front. Unfortunately the next eighty years of Pictish and Scottish history is exceedingly difficult to unravel, owing to the want of lists of kings and a reformer or two in the Annals of Ulster are all the material which is to hand. Ciniud was king after Brude, but his rights were disputed by Aed of Dalriada; and after his death in 774 there is much confusion in the Chronicles, as there must have been in the facts. Dalriadic princes struggle with Pictish princes and with one another for the throne, till Constantine of Dalriada established himself about 815 as king over both. His and his brother's reign ended in 834, and a time of confusion followed, native Pictish princes striving against Eoganan of Dalriada, son of the former. Pictish kings were in 839, which ended his reign, saw a great defeat and slaughter of the Picts by the Danes, with confusion once again, from which emerged in 844 Kenneth MacAlpin, the Scot, as king over both nations, henceforward not to be disputed. Many things indicate the great contrast in the western kingdom, such as it was, and of the Pictish language: the distinction, physical and otherwise, between northern and southern Picts; the rule of female succession which allowed Anglica Briton, and Scotic princes to rule in right of their mothers, with the consequent daughter were preferred to the son; matriarchy implies; and the superior culture of the Scots, Christian and literary. Nor must it be forgotten that we really do not know much about
the Jales and west coast north of Argyll, nor indeed of the counties north of Inverness, from the time of Brude MacMailchon till the Norsemen came. It is quite certain that the Scots colonised these very early, and had, indeed, established themselves in Perthshire. Aidan, the son of Gubhir, makes expeditions to workmen in the Picts and druidics among them on the Forth, or even farther eastward, in Mearns. This aggressive energy, combined with the other facts of the situation above enumerated, would easily enable the Scots to supersede the Picts in power and language.

It can now be part of the question what the language was which they spoke. This question must not be confused with another if allied one, What race did the Picts belong to? The Picts may have spoken a Celtic language though racially possessed of little Celtic blood, and may have retained non-Celtic customs as survivals of a lower culture, as indeed they did in the case of female succession. Four hypotheses have been formed in regard to the language and origin of the Picts. The first, started by Pinkerton and put by Sir Walter Scott into the mouth of the 'Antiquary,' is that the Picts were a Celtic-Frisian-Pictish-Gothic dialect; the second, maintained by Dr Skene, is that they were Gaelic-speaking Celts, and that they and not the Scots finally conquered in the 9th century; the third, due to Professor Rhys, is that the Picts were non-Aryans, whose language was one of the Jales, and known by that name; the fourth, held by two of the most eminent Celtic scholars of the day, Professor Windisch and Dr Whitley Stokes, is that they were Celts, but more nearly allied to the Cymry than to the Gaeil.

The materials for deciding the linguistic relation of the Picts to the modern Celtic-speaking nations consist almost entirely of names—those in the classical writers, in the king lists, and in the Book of Deer, and the still or lately extinct place-names of ancient Pictavia. The main agreement between the Gallo-Cyriic and Gaelic languages is their dropping of Arvan initial p; their main difference is their developing the labialised guttural gh— the one like the Greeks into p, and the other, the Gaelic, like the Latins into g or c. This fact led Professor Rhys to call them respectively P Celts and C Celts from Scotia and the Irish branch of the Celtic family. So, in the Gallo-Cyriic language the name Picti, which was usually regarded as the Latin for 'painted men,' is now considered inseparable from Pictiones or Pictavi of Gaul, now Poitou, and is therefore Celtic of the P group. An old Gaelic equivalent is supposed to be the name of Deir den Dubh in the Gelasian Psalter. The idea of 'painted or pictured men' intact. Further, the Gaelic name cruthin is derived from cruth ('form, figure'), Welsh pryd; and the Welsh name for Pict is actually Pryllon. The form Prettanica, undoubtedly used by the best Greek writers for the Latin Iucania, makes it possible that the Cruthinig gave their name to Britain. The meaning of Bede's Pictish word pienfæblh is practically explained by himself as Wall's Head, where pneu, with its p, answers to Welsh penu ('head') and not to Gaelic cean. Similarly Pern and paut in the king lists. It is not certain that meaning striking still is the pelt of the Book of Deer, which signifies a portion of land, corresponding to Welsh peth, and etymologically to Gaelic eitl ('portion'). Pet or pat is a prefix in place-names in Gaelic; and the football of the Forth at the present day, some two hundred being easily counted, although the Gaelic Bal has considerably extruded it in western Pictland. It is similar to aber as a place-name prefix, which is found all over Pictland. This is the Abber or Apar of the Pictland from Scotia and the Cynric to the Earth-houses (q.v.). The Brosch (q.v.) are also sometimes called Pictish Towers. For the Picts' Work, see Caractacus,

Picture-painting. See REHOGlyphics.

Piece of Eight. See PIStRE.

Piedmont, or PIEDMONT (Fr. pied, 'foot, mont, 'mountain'), a former Italian principality, which now forms the north-west part of the kingdom of Italy, is by the Alps separated from Switzerland on the N. and from France on the W.; on the E. lies Lombardy, and on the S. is Signa, to which the old duky of Savoy is attached. It included the duchy of Monferrat and part of the old duky of Milan, and now embraces the provinces of Alessandria, Cuneo, Novara, and Turin, and covers 11,389 sq. m., with a pop. (1889) of 3,297,157. For an account of its geographical features, see the preceding century. The 12th century the name Piedmont was used as a collective title for the territories ruled over by the House of Savoy on the east side of the Graian and Cottian Alps; the history of the region will be found under ITALY, SARDENIA, SAVOY, and WALD. See, too, Butler's Alps and Sanctuaries of Piedmont (new ed. 1890).
Piepowder Court, in England, an ancient court held in fairs and markets to administer justice in a rough and ready way to all comers, called also the Court of Dusty Foot (Old Fr. plied pointev). Its jurisdiction seems to have been confined mostly to petty vagabonds, pedlars, and other wanderers. It has since been obsolete, and its jurisdiction merged in the court of Petty Sessions (q.v.).

Pierce, Franklin, fourteenth president of the United States, was born at Hillsborough, New Hampshire, November 23, 1804. His father, Benjamin Pierce, a farmer who had risen in the war of independence to the rank of major, in 1827 and 1828 was a member of the New Hampshire legislature. Pierce was educated at Bowdoin College, and was an officer in a college military company, in which his biographer, Nathaniel Hawthorne, was a private. He graduated in 1824, studied law, and was admitted to the bar in 1827. From 1829 to 1833 he was a member of the legislature, and for two years was its speaker; he was then elected to congress, a Democrat of the school of Jackson. In 1837 he was elected to the United States senate, of which he was the youngest member. In 1842 he resigned his seat, and returned to the practice of law. In 1846-47 he was elected to the House of Representatives, and in 1849 returned to the Senate. As senator he represented the New England States and Illinois, while his major interests were the Mexican War, with which he was not, after his opponents, the Whigs and Free-soilers, had been victorious at the polls in 1846, volunteered as a private for the Mexican War. The president made him a brigadier-general, and in August 1847 he joined General Scott's troops in the vicinity of Vera Cruz and Churubusco. In 1852, in consequence of the conflicting claims of the leaders of the Democratic party at the Baltimore Convention, he was nominated as a compromise candidate for the presidency, against General Scott, the Whig nominee. He received the votes of all but four states. President Pierce in his inaugural address defended, on constitutional grounds, slavery and the Fugitive Slave Law; and his cabinet, which was an eminently able one, included Jefferson Davis as secretary of war. Pierce's view as to slavery was that it was inherent in the Constitution, and he framed bills to enforce the federal constitution, and that, therefore, in honesty it must be maintained. The principal events of his administration—in importance far before the treaty for reciprocity of trade with the British American colonies and the treaty with Japan, or the filibustering expeditions of Walker (q.v.) to Nicaragua, and of others to Cuba, with the resultant abortive Ostend (q.v.) Manifesto—were the repeal of the Missouri Compromise (see Missouri) and the passing of the Kansas-Nebraska Act (see Kansas), which kindled a flame of civil war. The subject of slavery was the subject that ultimately set the whole Union in a blaze. Pierce, with his rigid regard for constitutional obligations, was intensely hostile to the free-state settlers and to abolitionists in general. At the close of his term of office in January 1861, he went at once to Europe, and afterward, having no sympathy with the party which subsequently came into power, he took no part in politics. He died at Concord, 8th October 1869.

Pieria, a coast district of ancient Macedonia, at the base of the Olympus, and between the Penens and Haliacmon. It was the fabled birthplace of the Muses and of Orpheus.

Pierre, a city, capital of South Dakota, is on the Missouri River, 116 miles by tail W. of Huron. It has a pop. of about 12,000. Here are also situated a central office of the Mound City Railroad, and a government industrial school for the Indians. Pop. (1900) 2386.

Pierson, Henry Hugo, composer, was born at Oxford in 1815, in 1844-45 filled the chair of Music in Edinburgh, and from 1846 lived in Germany, dying at Leipzig, 28th January 1873. Among his works were the music for the second part of Goethe's Faust, an oratorio of Frere, and the oratorios Jerusalem and Hezakiah.

Piers Plowman. See Langland.

Pietà (an Italian word signifying pity, in the sense in which that term indicates or includes affection for relatives), the name given in the language of art to representations of the Virgin Mary embracing the dead body of her son. It is a counterpart to the Madonna with the infant Jesus in her arms.

Pietermaritzburg, or Maritzburg, capital of Natal (q.v.), occupies a fine situation near the Umsunduzi river, 54 miles N. of Durban, and 2218 feet above sea-level. The chief buildings are the Legislative Assembly buildings, Government House, the Colonial Offices, Town-hall (rebuilt 1890, after being burnt), the supreme court, the post-office, railway station, police barracks, &c. Fort Napier, the head-quarters of the imperial troops, overlooks the city from a hill on the south-west. There is a college library and museum, asylums, a park, botanical gardens, &c. The city takes its name from its founder, Pieter Maritz (1830-1885), the Boer leader. Pieter Retief and Gert Maritz. There is railway connection with Durban, with the Orange Free State, and with Johannesburg and Pretoria in the Transvaal. The place has steadily increased in importance with the development of the colony, especially since the establishment of the railways. Pop. (1887) 13,767; (1898) 34,593, about half whites, the rest Kaffirs and Indian coolies.

Pietists, a designation given at the end of the 17th century to a religious party in Germany, which, without forming a separate sect, was distinguished rather by fervour and zeal than by peculiarities in doctrine or religious organization. See History, Vol. III. p. 240, the articles on Spencer and Francke; and the Histories of Pietism by Hepp (1879) and Ritschl (1880-86).

Pietra-Dura, a name given to the finest kinds of Florentine mosaic-work, in which the inlaid materials are hard stones, such as Jasper, Carnelian, and others, with agate.

Piezometer (Gr. πιεζω, 'I press,' metron, 'a measure'), an instrument for measuring the compressibility of fluids, by observing the extent to which an air-bubble which marks the upper level of liquid in the capillary neck of a flask is depressed by the application of an external pressure acting through liquid surrounding the flask.

Pig, or Hog (Sus), a genus of artiodactyle ungulate mammals, of the family Suidae (see Boar), where the characteristics of the wild species are discussed, with an illustration). The term Swine is commonly applied to the genus in Britain. The body is covered more or less with bristles and hair; the skin is very thick; the limbs short and stout; the neck, which is carried straight forward from the trunk, is very thick and strong; the face moderately prolonged and truncated, always terminating in a movable cartilaginous disc, furnished, as in the mole, with a special small bone, and employed with wonderful expedition in
turning up the soil in search of roots and other food. In most of the improved varieties the face is much shorter than in the wild boar or ancient pig. There are six incisors, two canine teeth, and fourteen molars in each jaw, the lower incisors projecting forwards; the canine teeth long and strong, projecting and curved, becoming in Chinese and African species long and sharp tusk-like weapons in wild boars, and large and powerful even in the females in a wild state. The feet have each four toes, the lateral ones small, and scarcely touching the ground, all separately hoofed. The tail is short. The stomach shows more traces of division. The food is chiefly vegetable, but pork or beef no more animals may more properly be called omnivorous; and although, even in a wild state, pigs are not to be reckoned among beasts of prey, they are not unfrequently, even in domestication, kill and eat small animals that come in their way, as many a housewife has had occasion to observe in respect to chikens. The Common Pig (S. scrofa) appears to be a native in the wild form (see Boar) of most parts of Europe and Asia; the domestic European breeds are apparently descended from the European wild boar, crossed with domesticated Asiatic breeds. Like the other thick-skinned animals with which it is allied—the elephant, rhinoceros, hippopotamus, and tapir—the pig delights in humid and shady open places. The pig usually grows until five years old. Its natural life ranges from fifteen to thirty years. The pig, like the wild boar, was prohibited to the Jews, and the prohibition has been adopted in the Mohammedan law, the pig has been a domesticated animal from a very early period, and its flesh constitutes a large part of the food of many nations. The fecundity of the pig is great; with proper treatment it will produce two litters annually, generally of four to eight pigs each, although sometimes there are as many as fourteen in a litter. Vast quantities of the flesh are consumed in various forms, as pork fresh or salted, bacon, ham, &c. Brawn (q.v.) is an esteemed luxury. The fat of the pig, which is produced in a thick layer under the skin, is an important article of commerce, and of various use under the name of Lard (q.v.). The skin of the pig is made into leather, which is particularly esteemed for saddles. The bristles, especially of the wild boar, are much used for brushmaking. Indeed, there is no food-producing animal which is of greater benefit to mankind than the pig.

There are numerous varieties of the domestic pig. Some have erect and some pendant ears, and those are most esteemed which exhibit the

of the breeds commonly reared in Britain, giving rise to the improved white and black breeds respectively. The Chinese breed is renowned for its fertility, as well as for the rapidity with which, without materially increasing in offal or bone, it lays on flesh. Its head is short and thick, ears erect, legs very short, and the chine—chop—five inches long, jowl wide, belly hanging very near to the ground. As a rule it carries a small quantity of hair. The skin isnaturally dark, but the flesh is delicate and white. These valuable characteristics distinguish the improved Yorkshire pigs, which are much esteemed all over the British Isles as well as in several foreign countries. The Neapolitan breed is entirely black, with little hair, moderately short in the face, ears small and erect, short in the leg, moderately long and thick in the body, remarkably easy to fatten, but scarcely so robust in constitution or so prolific as the Chinese pig.

Besides many local varieties of recognised merit, there are at least six improved breeds of swine reared extensively in the British Isles. The White Yorkshire are divided into the three sub-varieties known as the Larghorn, and Suffolk and Berkshire breeds. Then there are the black Berkshire, the Suffolk breed (some black and others white), and the red Tamworth. The black Suffolk pigs are sometimes spoken of as the Small Black breed. The Tamworth is a large-sized pig, rather stronger in the bone than the other sorts, with a long face. It is noted for a high proportion of lean meat. The Large White is the most widely distributed variety. It is being used extensively and with excellent results in the improvement of the pigs in Ireland, Scotland, and on the continent of Europe. The pigs of America are descended mainly from the Berkshire, Poland-China (a breed developed in 1816-38), white Suffolk, Chester, Cheshire, Essex, Jersey red, and Victoria (a breed originating at Saratoga about 1853). The first swine seem to have been introduced into Hayti by Columbus in 1493, and into Florida by De Soto in 1538; within a century pigs bred in Virginia, Canada, and Nova Scotia. The extent of the pork-packing business in America may be estimated from the figures given at Chicago. See also PORK. It used to be said that pigs were indigenous in the Polynesian area, but most likely they were introduced by the earliest navigators. Allowed to run wild, they multiply rapidly under favourable conditions; thus in New Zealand they became at one time a nuisance, and in Nelson province three men killed 23,000 pigs in twenty months.

Pigs are profitably kept wherever there is much vegetable refuse on which to feed them, as by cottagers having gardens, farmers, millers, brewers, &c. They are often allowed to roam over fallow ground, which they graze up for roots, and over stubble-fields, which they glean very thoroughly. It was an ancient practice to allow pigs to feed in woods, where they consumed acorns, beechmast, and the like. When they are fed, as is sometimes the case, chiefly on animal garbage, their flesh is less palatable and less wholesome. The pig has a reputation, which it does not deserve, of peculiar filthiness of habits. It is true that it wallows in the mire, as the other pachydermata also do, to cool itself and to provide itself with a protection against insects, and it searches for food in any puddle; but when it is in a pig-sty, it is kept scrupulously clean. The too common filthiness of pigsties is rather the fault of their owners than of their occupants; and a clean and dry sleeping-place is of great importance to the profitable keeping of pigs.

The Hog Cholera or Swine Plague, due to the presence of a bacterium, caused terrible havoc in the United States in 1870-80, though hardly
known twenty years before. As in the splenic fever of sheep, due also to bacteria, attempts have been made to ward off the more violent form of the disease by inoculating animals with a milder type.

The pig is not inferior to other quadrupeds generally in intelligence, but it excels most of them in obstinacy. It can be easily rendered very tame and familiar. Its acuteness of scent has been turned to account in making it search for truffles; and a tale is told of a pig having been successfully used as a pointer. The pig has sometimes served as an agent of forgery.

The Bush Vark, or Bush Hog of South Africa (Chasœrotamus africanaus), is about 2 feet 6 inches high, covered with long bristles; it has projecting tusks, a large calous protrusion on each cheek, and long, sharp, tufted ears. It is gregarious, subsists chiefly on vegetable food, and makes destructive inroads on cultivated fields. The forests of the island of New Guinea produce a species or variety of pig (S. papuensis) more widely different from the common pig than its breeds are from one another. It is 15 or 20 inches high, with short ears, and very short tail. The Babirussa (q.v.) is another species of pig; see also WART-HOG.

See Columb, Swine Husbandry (New York, 1877); Gilbert, Pigeon-keeping for Amateurs (1882); Long, Book of the Pig (2d ed. 1889).

Pigeon (HtL. piperace, piccione, or pipione, from piper, 'to peep or cheek'), a name sometimes applied, like Dove (q.v.), to all the species of Columbidæ, and sometimes almost restricted to those still included by ornithologists in the genus Columba; having a bill of moderate length, hard, and a little arched at the point, the base of the upper mandible covered with a soft thick skin, in which the nostrils are pierced; the feet with toes divided to the base, and formed both for walking and perching; the wings rather large and pointed; the tail of moderate length, and generally square at the end. The species of this group are very numerous, there being nearly 150 different kinds, and they are found in all parts of the world. Some of them build their nests in trees, and others in rocks. They invariably lay only two eggs at a time, but breed several times in the year, both the male and the female taking part in the process of incubation, and besides feeding in young birds. The origin of all the domesticated varieties of the pigeon is the blue Rock-pigeon (C. livia), the Baiser of the French, a bird of extensive geographical range, being found as far north as the Faroe Islands, and in nearly all parts of the eastern hemisphere. It is found in large numbers on the British coast, particularly on the Orkney Islands and the Hebrides, and also in the Mediterranean. Its food consists partly of molluscs and other small animals, and partly of grain and seeds; and it often pays unreserved visits to the cornfields, raiding with equal state the blue rock-pigeon exhibits great uniformity both of size and plumage; it is not quite 12 inches in length from the tip of the bill to the end of the tail; the prevailing colour is bluish grey, in some parts with green and purple reflections, and having two broad and distinct black bars across the closed wings; the lower part of the back is whitish; the tail is a deep grey with a black bar at the end; the bill is dark brown; the legs and feet reddish orange.

There are also the Stock-dove or Smaller Wood-pigeon (C. cuneata), found all over southern and mid Europe, Asia Minor, and the Russian Empire; the Rock-dove, Wood-pigeon, or Cushat (C. palumbus), very common in all parts of Europe and Asia and in northern Africa, and the largest of the British species. These are all the British species of pigeon. In addition we may mention the Ring-tail Pigeon (C. caribaea), a West Indian species; the Bald-pate or White-headed Pigeon (C. leucocephala), also found in the West Indies and Florida; the Double-crested Pigeon (C. dilophus), found in the northern parts of Australia, and having, as its name indicates, a double crest, one b tł the back part of the head, and the other springing from the forehead. There are other varieties, too numerous for mention.

As already stated, only the blue rock-pigeon has been domesticated, but this species lends itself very readily to the restrictions of civilised life. The changes brought about in it are very varied and remarkable; and the description of his experiments upon the pigeon by Darwin arc of the deepest interest. For many centuries and in all lands pigeon-breeding has been a favourite pursuit with all classes of society. In India several of the native rulers have very extensive establishments for the breeding of pigeons. In Persia and in Asia Minor the pigeon is very largely and carefully bred; and in the latter country especially many of our most beautiful varieties have been produced. From North Africa we have also received at least one fine breed. Throughout Europe this pursuit is followed with a great amount of enthusiasm, more especially in Italy, Germany, France, and Belgium, as well as the United Kingdom. In Belgium the sport of pigeon-flying or racing is the national sport engaged in by all sections of the community; and to that country we owe the variety known as the Homing Pigeon (see CARRIER PIGEON). In the United Kingdom, as in America, there are enormous numbers of breeders who devote themselves to what are known as 'fancy pigeons,' by which term are known those breeds for their special points or characteristics. Of these there is a great and ever-increasing variety, which it is impossible to describe in detail, as there are in all some two hundred breeds, many of which have several distinct colours. The following are some of the most prominent: Carrier (q.v.)—This is not, as is commonly supposed, a member of the homing family, though undoubtedly it was at one time used to carry messages. It is much longer in feather than
PIGEON

PIGMENTS

The blue rock, and is specially characterised by having an abnormal development of the beak and eye wattles, the former of which is like a round 3lesley ball pierced by the beak. Dragon.—Of a similar type, rather lighter in body, and with less height, is the British Magpie, which is better known as a pigeon, but in this ease the eye-wattle is the chief point, and it is bred so that the head has the appearance of a bobbin or reel. These three varieties make up the Wattled Pigeons; and they are all very valuable when bred to perfection. Pouters.—The Pouter is usually a double pigeon, arising from the great development of the crop, which has a globular form, and stands out from the neck. Of these the best known is the English Pouter; and there is also the Norwich Cropper; the former a large bird, and the latter a smaller one. The smallest of this family is the diminutive Dimy Pigeon. In these the head, which is at the back of the crop, is often almost buried by it. Jacobin.—A breed in which the head and neck feathers are largely developed, the former in the shape of a hood, so that the head is often the latter falling on to the shoulders, leaving a round space between, known as the roe. Fantail.—In this the characteristic which gives the variety its name is that the tail-feathers spread themselves out transversely to the body in the resting position, and is even longer in the male. The head is thrown back, often touching the tail, with a nervous motion, the body poised on short legs, and the bird looking as if it were falling backwards. Tumbler.—In these the name is derived from the tumbling or burning motion when flying, so that the head is often curled up in the crop, with the tail flowing out. Pigeons, Frizzled Pigeons, and the Tilpiners.—These include a very large variety, the greater portion of which originated in the Orient. They are thus called because the throat or chest is decorated with a frill of curled feathers, more or less perfect. Some have in addition a crest on the head, and there is an almost endless variety of colour and of markings, the richest—those known as Oriental Frills—being of much later introduction than the Ows and Turbitts. One, the White African Owl, is the smallest of all domestic pigeons, and comes from Tunis. Anteversa. —A very massive-built bird in which there is a considerable admixture of homing blood. Of the other prominent varieties the homer has already been referred to; the Russian Trumpeter has a large crest and very prominent leg-feathering; the Hunt is the largest of all pigeons, and on the table. The system of exhibitions which has grown up of late years has done much to stimulate the breeding of fancy pigeons, and very high prices are paid for the best specimens. On numerous occasions £100 has been given for a single pigeon, and £50 is quite a common price.

For the keeping of pigeons different forms of houses may be adopted. When they are permitted to fly about they may have either small coops for, say, four pairs, mounted on tall poles and then can be made attractive—or they may be accommodated in larger houses. Fancy pigeons are usually restrained by what are called flights or aviaries, which consist of a large space attached to the house, the sides and top made of wire-netting, so that the birds cannot get away. It would be too great a risk to permit valuable birds to fly. Whether in confinement or at liberty each pair of pigeons must be supplied with a nest of their own, which is better kept separate, as often they sit at the same time. In the nest-boxes pans are placed of the usual construction for this purpose. Pigeons are prolific breeders, and will lay several nests during the year, each containing a couple of eggs. Poets, male and female, if permitted to do so, continue faithful to each other from year to year, a circumstance noted by Pliny and others of the ancients.

See DOVEKET, and books on pigeons and pigeon-keeping by Tegetmeier (1866), Piper (1871, Foufion (1876), Brent (1876), Wright (1879), Lucas (1886), Ure (24 ed. 1889), Lyall (1889), and the present writer (1891).

Pigeon-shooting. In the days of the Red House, at Battersea, the members met four times a week in their enclosure on the banks of the Thames for the purpose of pigeon-shooting. The traps mostly in use at that time were what are now known as "T. T. Traps." The latter were large and heavy when men like Lord Huntingfield, Lord Winchelsea, Lord Kennedy, Sir Richard Sutton, Sir Charles Kent, Captain Ross, and Mr George Osbaldeston were present. Captain Ross in 1828 killed at 30 yards rise, from five traps, seventy-six birds out of the other four settled on the fence, and the fourth bird was hard hit, although the shooter's first barrel missed fire. The shooter handled a 12-bore gun by William Moore, charge of powder and shot unlimited. Captain Ross and the Red House Club enjoyed a match at 25 yards, both in 1828 and 1829; and in 1841, in a match at Edinburgh with Lord Macdonald, he at 35 yards killed fifty-two birds out of fifty-three. When the Red House Club was closed in 1850, trap-shooting was for some years out of fashion, until it occurred to Mr Frank Heathcote that a system of handicapping might be advantageously adopted in order to place good and bad shooters on something like an equality. Many successful meetings were now held under Mr Heathcote's management at the Old Horsey Wood House, until the ground was sold. He then established on the Greenheath, and Mr Heathcote in 1867 rented for £700 a year the Lighthouse estate at Fulham (q.v.); and a club being formed, the property was subsequently purchased for £20,000. After the appointment of Captain the Hon. D. J. O., as manager, the club flourished to such an extent that for several years prior to 1891 it had its full complement of 1500 members, under the presidency of the Prince of Wales. As regards the shooting members there are not more than 200, and fully half of these never fire at a pigeon. This can easily be accounted for, as a gentleman can get himself elected almost immediately as a shooting member, whereas in the ordinary ballot for members he might have to wait two or three years. In 1851 over 200 candidates were down for election, and only 15 guineas, with an annual subscription of 5 guineas. The polo ground is the best in the country, and during the height of the London season it is nothing unusual to see three or four thousand of the elite of London society in the park and grounds.

Pigments used in artistic work vary much in permanence. A few of the pictures painted by distinguished artists during the 18th and the first half of the 19th century are already more or less faded by the action of light or otherwise injured by impurities in the atmosphere of rooms. It
impudent to expose any kind of artistic work in colours to direct sunlight or even, it would seem, to the light of electric arc lamps. The following refers to the durability of pigments employed in this way, to which the historian should also be fairly strongly daylight. Among blue colours, ultramarine, both real and artificial, is permanent; while Prussian blue is liable to some change, and indigo is fugitive. Among red colours, vermilion and the red ochres are perfectly durable; while the redder reds and purples can hardly be thrown thoroughly relied upon, and the carmine and crimson lakes, from cochineal, quickly give way. Among the yellows, raw sienna, yellow ochre, as well as the cadmium and Naples yellows, are quite stable; while Indian, chrome, and lemon yellows, and their mixtures, are much liable to change, and as brown, and Caledonian brown do not at all fade; but hardly as much can be said of madder brown, Cologne earth, and Vandyke brown, although these are fairly durable. Asphalum or bitumen has a tendency to move on the canvas unless very carefully applied, and its colour is also altogether permanent. Lampblack, ivory black, and charcoal black are quite durable, so also are flake white, zinc white, and baryta white. It is generally the case that a colour produced by a mixture of permanent pigments is also permanent, and it may be added here that flake white (with lead), so much used to mix with other colours for light tints, is liable to discolor when exposed to sulphurised hydrogen (an occasional impurity in coal-gas), and this colour has also a tendency to tarnish when kept in the dark.

The above remarks on colours made up with oil apply equally to water-colour pigments, with a few exceptions. These are vermilion, especially if artificial, Naples yellow, chrome yellow, and madder brown, the permanency of which cannot be relied upon in Water-colours, under which head some further information may be found.

Fuller information about the pigments named above, as well as others, will be found under the heads Asphalt, Black, Blue, Green Pigments, Lakes, Ochres, Purple Colours, Red Colours, and Yellow Pigments. The oils and varnishes used with these pigments, as well as the nature of the prepared canvas or paper used for painting upon, have all a bearing on the preservation of the colours of a picture. See the Chemistry of Paints and Painting, by A. H. Church (1890).

The history of the introduction of the principal pigments is given at Painting, Vol. VII. p. 702.

Pigments of Animals. That animals are often brightly coloured is evident. Some of the simplest, such as many Radiolarians, are brilliant; sponges are often suffused with pigment; sea-anemones and corals are justly compared to flowers, many marine worms have an iridescent sheen; the Echinoderms are almost always bright; many crustaceans have a jewel-like radiance; myriads of insects are iridescent; the shells of mollusces are rich in beauty; the fishes gleam in silver and gold and many hues; even the amphibian reptiles are multicoloured; certain lizards and snakes seem like flashes of colour; birds are often brilliantly decorated; and mammals have a subdued but often rich colouring in their fur. But all the colours of animals are not due to pigments, for air-spaces in hairs and feathers make these structures white; crystals of guanin or lime often produce a silvery glimmer; striation and other physical peculiarities of the surface cause iridescence.

The most important Pigments. — (a) Pigments called lipochromes are among the commonest, occurring in living bodies, and some of them are exposed to sunlight, although they do not seem to be fairly strong daylight. Among blue colours, ultramarine, both real and artificial, is permanent; while Prussian blue is liable to some change, and indigo is fugitive. Among red colours, vermilion and the red ochres are perfectly durable; while the redder reds and purples can hardly be thrown thoroughly relied upon, and the carmine and crimson lakes, from cochineal, quickly give way. Among the yellows, raw sienna, yellow ochre, as well as the cadmium and Naples yellows, are quite stable; while Indian, chrome, and lemon yellows, and their mixtures, are much liable to change, and as brown, and Caledonian brown do not at all fade; but hardly as much can be said of madder brown, Cologne earth, and Vandyke brown, although these are fairly durable. Asphalum or bitumen has a tendency to move on the canvas unless very carefully applied, and its colour is also altogether permanent. Lampblack, ivory black, and charcoal black are quite durable, so also are flake white, zinc white, and baryta white. Pigments

Poulton that surrounding colours modify those of some caterpillars, and J. T. Cunningham has described the long flat and usually transparent scales on the inner side of the third abdominal segment of insects, which reflect the sunlight in various ways to give bright metallic or iridescent hues.

In many insects and reptiles, the scales reflect and absorb light in such a manner that the body is colored or camouflaged in such a manner as to elude the eyes of the observer. The scales, which are located on the body of these animals, are iridescent and have the ability to change color. The iridescence is due to the structural properties of the scales, which are composed of a protein called pterin. Pterin is a pigment that is responsible for the iridescent coloration of various species of insects and reptiles. The color of the iridescent scales is determined by the thickness and orientation of the scales, as well as the wavelength of the light reflecting off the scales. The scales are typically thin and have a layered structure, with a thin layer of pterin on the inner side of the scale and a thin layer of air on the outer side. The thickness of the scale and the orientation of the layers determine the color that is produced. For example, if the layers are oriented in a way that causes light to interfere constructively, the scale will appear metallic in color. Conversely, if the layers are oriented in a way that causes light to interfere destructively, the scale will appear non-metallic in color.

The iridescence of the scales is due to the constructive and destructive interference of light. Light from a source, such as the sun, is reflected off the scales. The light then passes through the scale and is reflected back to the observer. The light is split into two beams, one traveling through the scale and the other traveling through the air. The two beams travel at different speeds and are therefore out of phase when they reach the outer surface of the scale. This out-of-phase interference results in a loss of intensity, and the scale appears non-metallic in color.

The iridescence of the scales is a complex phenomenon and is influenced by a variety of factors, including the thickness and orientation of the scales, the wavelength of the light, and the angle of incidence. The iridescence is a function of the interference between the light reflected off the scales and the light transmitted through the scales. The interference pattern is determined by the thickness and orientation of the scales, as well as the wavelength of the light.

The iridescence of the scales is a remarkable example of how nature can use simple structures to produce complex and beautiful effects. The iridescent scales of insects and reptiles are a testament to the beauty and complexity of nature.

Pike

Pike (Esox lucius). — The common pike is said to spawn when three years old. The male is usually half as long and half as thick as its mate, but the spawning is protracted. There is great mortality among the young, which take about a week to hatch. Growth is at first rapid, and continues more slowly for years. The longevity of the fish is great, but the records of pike which have attained to 200 years are as unsatisfactory as the evidence for longevity usually is. There is no doubt, however, that they may outlive their keepers; and it is also true that they sometimes venture aashore, and that they sometimes lie in a torpid slumber in the pools. But the most characteristic quality of pikes is voracity. Feeding for the most part on frogs and small fishes, they are often prompted by hunger to bid for higher game, such as ducks, geese, water-hens, and water-rats. Thorne describes the pike as the "swiftest, coarsest, and most ravenous of fishes, which Josselyn calls the river-wolf. It is a solemn, stately, punctual fish, lurking under the shadow of a lily-pad at noon, with still, circumspect, voracious eyes; motionless as a jewel set in water, or moving slowly along to take up its position; darting from time to time at such unholy fish or frog or insect as comes within its range, and swallowing it at a gulp. Sometimes a striped snake, bound for greener meadows across the stream, ends its undulatory progress in the same receptacle." The Bony Pike (Lepidostoma) is a Ganoid, and the name is sometimes applied to the marine Gar-pike (Belone) and to some American perchels. See Bony Pike, Gar-pike.

See the articles ANGLING and PISCICULTURE; Parnell's Book of the Pike (3d ed. 1884); and Bickerdyke's Angling for Pike (1888).

Pike, a word loosely used for almost any kind of lance or Spear (q.v.), whether larger or smaller headed, as used by infantry troops, and now superseeded by the bayonet. The naval boarding-pike is a lance about the length of a man. The short pike, called half-pike or spontoon, long carried by some classes of infantry officers in most European armies, was a kind of Halbert (q.v.) with a smaller but ornamented head, and was rather an emblem of dignity than a fighting weapon. In 1804, when a French invasion was threatened, pikes were distributed by government through the country; and the secret manufacture of iron pike-heads was one of the principal features of domestic industry.
the most disquieting features of the Radical reform agitation in 1819 and during the Chartist troubles.

Pike's Peak, a peak of the Rocky Mountains, in Colorado, 65 miles S. of Denver, by Captain Pike, U.S.A., in 1806. It is situated in 38° 50' N. lat. and 106° 2' W. long., and rises to a height of 14,134 feet, making it one of the highest meteorological stations in the world; while at the base, at Colorado Springs, there is a low-level station. A railway to the top, 9 miles long (41 miles of curves), with a maximum gradient of 1 in 4, has been constructed.

Pilaster, in Classical Architecture, a square pillar, sometimes standing free, but usually attached to a wall, from which it projects 1st, 3rd, or other definite proportion of its breadth. Greek pilasters, or antae, were of the same breadth from top to bottom, and had different capitals and bases from those of the orders with which they were associated. The Romans gave them a taper like the columns, and the same capitals and bases.

Pilate, Pontius, the fifth Roman procurator of Judaea and Samaria, from 26 to 36 A.D. He was personally convinced of the innocence of Jesus, and tried to save him, yet sent him to be crucified to appease the raving mob of Jerusalem, washing his hands before the people to show that he took no responsibility for his death. His rapacity and cruelties caused many outbouts, which were sternly suppressed, and at length culminated in the murder of a number of Samaritans on Mount Gerizim, which caused such loud complaints that Vitellius sent him to Rome to answer to Caesar (36 A.D.). Eusebius tells us that Pilate made away with himself; others say that he was banished to Vienna Allobrogum (Vienne), or beheaded under Nero. In the Eastern Church there is a persistent tradition that he eventually embraced Christianity like his wife, and indeed in the Russian Church Pilate is commemorated as a saint, his day falling on June 25. Pilate is said by Justin Martyr, Tertullian, and Eusebius to have forwarded to Tiberius for his own justification an account of the judgment of Jesus, but the so-called Report, and Acts of Pilate, as well as the two letters of Pilate to Tiberius, have no claim to authenticity.

Many legends have clustered round the sinister figure of Pontius Pilate. One relates how his body was flung into the Tiber, and caused the river to overflow, and how it was next thrown into the Rhone near Vienne, but according to the latest form of the medieval legend) again caused such a storm that it was carried to Mount Pilatus near Lucerne, and there sunk securely in the deep pool on its top. But here again it made storms arise, and every year to this day on Good Friday the devil lifts him out of the pool and sets him on judgment-seat, where he washes his hands now.—Pilate's wife, traditionally called Priscilla or Claudia Priscilla, from her solemn warning to her husband against putting Jesus to death, has been regarded as a Christian by Origen, Chrysostom, and Hilary. In the Greek Church she is a saint, her day falling on October 27. See R. A. Lipsius, Die Pilatus-Arten (Kiel, 1871).

Pilatus, Mount (Lat. Mons Pilatus, 'the hooded pen' from its top being frequently enveloped in cloud; the legends connecting Pilate (q.v.) with the place have presumably grown out of the altered name), an isolated mountain at the western end of the Lake of Lucerne, rising opposite the Rigi. The lower half is clothed with wood and meadow, where in summer over 4000 head of cattle are pastured; the upper portion is a mass of bare and jagged peaks, rising in the Tomlishorn and Pilatus Plateaus. The mountain is one of the highest meteorological stations in the world; while at the base, at Colorado Springs, there is a low-level station. A railway to the top, 9 miles long (41 miles of curves), with a maximum gradient of 1 in 4, has been constructed.

Pilgrim, or Pilaf, a dish common in Turkey, Egypt, Syria, and India, consists generally of rice, thoroughly boiled, drained, and gently stirred with butter, pepper, and finely-chopped onions. For the tables of the wealthy, fowls, lamb, mutton, shreds of ham or bacon, variously cooked, but always much boiled or roasted, are placed on the top of the rice, and served up with it.

Pilchard (Clupea pilchardus, or Almas saradine), an important fish of the family Clupeidae. The pilchard is nearly equal in size to the herring, but rather thicker, and the lines of the back and belly are straighter; the scales are also larger and fewer; and the dorsal fin is rather farther forward. The mouth is small, and in the adult fish destitute of teeth; the under-jaw is longer than the upper.

The upper part of the body is bluish green, the sides and belly silvery white, the cheeks and gill-covers tinged with golden yellow, and marked with radiating strips, the dorsal fin and tail dusky. The pilchard is an inhabitant of more southern seas than the herring. In British seas it is abundant off the coasts of Devon and Cornwall, and the south and south-west coasts of Ireland; towards the east end of the English Channel it becomes scarce, and off the more northern coasts of the British Isles it is only taken occasionally in small numbers. Extending in abundance through the Bay of Biscay, along the west coast of Portugal, and the shores of the Mediterranean; its southern limit is Madeira. In France this fish is known as le sardine. It is true that the sardines in oil imported into Great Britain are smaller than the majority of English pilchards, but they are of the same species. The English pilchard is usually about 10 inches long. The French sardine is said by Moreau to be from 12 to 20 cm. in length—i.e. 5 to 8 inches—sometimes reaching 25 cm. or 10 inches. The fish used for preserving in France are certainly young and not full grown. Pilchards are now prepared in oil in the same way as French sardines, at Mavagissey in Cornwall, and have an extensive sale; so are Sprats (q.v.) at Deal. The fish are captured both by drift-nets and seines; the former method is pursued along the south coast of Devon and Cornwall, while the principal seat of the seine-fishery is Tyne. The drift-net fishing begins in August and continues with fluctuations until the following April, the largest number being landed in November, December, and January. The drift-nets are between 120 yards in length and a fleet consists of twelve to fifteen, fastened together, and extending to nearly a mile. They
PIECOMAYO

are 6 fathoms in depth, and the meshes are usually thirty-six to thirty-eight to the yard. The mesh of the nets used on the French coast is much smaller, not exceeding the hand's breadth. The seine used at St Ives are 160 fathoms long, with a depth of 8 fathoms at the centre, and 6 fathoms at the wings; the meshes are 2⅞ of an inch square. In the seine the fish are not meshed: if they were they would cause the net to sink. There are several stations or fords for fitting the lines of the seine at St Ives, and over two hundred seines. The nets are therefore divided into groups, and each net has to await its turn at the station to which it belongs. The regulations of the fishery are contained in the Sea Fisheries Act, 1868, 31 and 32 Vict. c. 43, sect. 68. The seine-fishery is carried on principally between August and Christmas. Most of the pilchards landed in Devon and Cornwall are salted for the Mediterranean market, especially Italy. They were formerly cured dry, the fish being piled in heaps with salt on a floor, and the brine drained away from them constantly. After remaining thus about a month the fish were sifted from the salt, washed, packed in barrels, and subjected to pressure which forced more oil from them. But at present the salting is carried out in water treading, so that the brine rises over the fish, and they are kept steeped in the liquid for several weeks or months. They are then washed, packed, and pressed as before, the oil being collected and sold principally for the use of leather-dressers. This wet process produces much cleaner and brighter fish than the old one.

Twelve thousand to fifteen thousand hogsheads of these cured pilchards are annually exported to the Mediterranean, each hogshead containing from 2500 to 3000 fish, and weighing 476 lb. gross. A large number of pilchards are also used as bait, especially in long-line fishing, and a good many are eaten fresh locally or in distant markets.

Unlike herrings, the pilchards which are captured are not in breeding condition, but are fat, with small reproductive organs. In fact the habits of the pilchard are the direct converse of those of the herring, pilchards being found feeding near shore, in more or less abundance for nine months of the year, but in June, July, and August, when as a rule none are being caught near shore, spawning pilchards are found at some distance, 10 to 50 miles or more, from land. At this time the females are occasionally taken in mackerel nets, in which the largest ones are meshed in consequence of their swollen condition. The ovum, unlike those of the herring, are quite transparent, and buoyant like those of the cod and mackerel; they pass through their development while suspended separately in the sea-water. Like the herring, the pilchard feeds upon minute crustaceans and other animals, some adult, some larval, which swarm in the sea.

The principal foreign fisheries are at Corunna and other places in the Bay of Biscay, the mouth of the Tagus, and the Bay of Biscay. In New Zealand and many other ports in the Mediterranean. In Scotland the pilchard is known as the Gypsy Herring, Gorrie Herring (the sprat being Gorrie), or Crevia Herring.

Pilcomayo, a river of South America, which takes its rise in two branches in the Bolivian Andes, runs southeasterly, forming a winding course south-east through the Gran Chaco, separating Paraguay and Argentina, and finally joins the Rio Paraguay a little below Asuncion. Its length is said to be 1700 miles, but this is mere guess-work, as no one yet has explored its entire course. Carried on a raft by a boatman's toll, it is a basis on which to estimate the whole. The volume of water brought down is comparatively insignificant, much being spent in lagoons on its way; at the mouth there is scarcely any perceptible current, and the breadth is not 60 yards, while within the first 200 miles it narrows more than once to less than 20 yards, and moreover divides into branches, and some of which explorers, like Captain Page, have lost their way. There have been many attempts, all fruitless, made to open the river route between Argentina and Bolivia: since 1556 a score of expeditions have been sent out, and many of the explorers have perished. Some have obtained 6-fathom soundings for 250 miles from the mouth, but then came rapids, where the river was not more than 2 feet deep; the upper stream, too, is rendered impassable by numerous rapids, and long canals would be required to open the river to navigation. In its upper course its sands are auriferous and the banks fertile; lower down the valley is swampy. The river's water is rendered like brine by the great salt lakes of the Chaco—in which part the river is buried for hundreds of leagues in a great forest of fan-palms.

Piles are usually squared logs of wood used in engineering operations, such as dams, bridges, and roads (see Cofferdam, &c.). They are sharpened at the point, and, if necessary, protected with iron bands, to enable them to cut across the part they encounter as they are driven into the ground. Piles are also used for permanent works, when they are driven through loose soil till they reach a firm bottom, and thus form a foundation on which buildings or piers may be erected. Pile-driving machinery is also used for piles, which are cast hollow. Common piles are driven in by machines called pile-drivers. In these a heavy weight (or monkey) is raised to a considerable height between two guides, and then let fall on the head of the pile. The application of this strain to these drivers has made them very powerful engines—Nasmyth's steam-hammer being a well-known instance. See also Lake-Dwellings.

Piles, or Hemorrhoids, are small tumours situated either within or on the verge of the anus. The first step in their development is the dilatation of one or more veins in this region. They consist of folds of skin or mucous membrane, with the subjacent tissues in an inflamed, infiltrated, or permanently distended condition. Many contain enlarged veins, though these sometimes become obliterated. There are several varieties of these tumours. Sometimes the pile is mainly composed of a little knot of varicose veins; in this case it is readily emptied by pressure of the fluid blood contained in it; it may, however, be cured only when the pressure is removed. Sometimes the blood coagulates, either in a dilated vein, or, if this has given way, around it, forming a solid tumour surrounded by tissues thickened in consequence of inflammation; or the tumour may consist of a kind of erectile tissue formed by an abnormal condition of the vessels of the mucous membrane; this variety is especially liable to bleed. These tumours are divided into bleeding and blind piles, according as they are or are not accompanied with haemorrhage; and into internal and external piles, according as they are within or without the sphincter muscle of the anus.

The following are the general symptoms of this affection. The patient, after having experienced for a varying time a dull pressure in a variable way, and in a varying degree, suddenly becomes conscious of a sensation as if there were a foreign body in the anus, and on examination after an evacuation discovers a small tumour, usually about the size of a grape, which either remains outside or is retracted into the anus, but is often introduced without, or within the sphincter. This tumour gradually increases, and others form around it, until a mass at length results as large as a pigeon's egg, or larger. In its ordinary inoffensive state the tumour

PILES

177
has little sensibility, and occasions comparatively little annoyance; but when it is inflamed (from stranguination by the sphincter muscle, or from any other cause) it is exquisitely tender to the touch, and is the seat of burning and stinging sensations, rendering the evacuation of the bowels (and sometimes also) difficult and painful. In women an inflamed pile may cause pain in the back, irritation of the womb, with mucous discharge, and many other anomalous symptoms. In severe cases the patient can neither stand nor sit with comfort, and only finds relief in the horizontal position. Piles and piles are not only a most important symptom, sometimes the first to be noticed, is hemorrhage, which may be so profuse as to threaten the patient's life.

Piles may be caused by any circumstances which cause congestion in the lower bowel, such as luxurious and sedentary habits of life, pregnancy, and such diseases of the liver as tend to check the return of blood from the veins of the rectum. Moreover, anything that causes irritation of the rectum, such as excessive use of purgatives, dysentery, inflammation of the prostate gland, &c., may cause piles. In all cases, hemorrhage is probably the most frequent; it operates in producing them partly by the pressure of the accumulated and hardened feces upon the veins carrying the blood away from the rectum, and partly by the straining and irritation such feces occasion during the passage of the bowels.

In the treatment of piles it is expedient to relieve the congested state of the lower bowel by one or two doses of sulphate of magnesia, and a cooling vegetable diet, after which the continued use of mild laxatives should be resorted to. A teaspoonful of coffee-water, consisting of a confection of senna, half an ounce of cream of tartar, and half an ounce of sulphur, if taken in the middle of the day, usually acts gently about bedtime, which is far the best time for the bowels of patients of this kind to act, as the parts irritated by the passage of the evacuation become quieter during the night. In long-standing cases, in which there is general relaxation of the mucous membrane, the confection of pepper in doses of a drachm may be given twice daily with advantage, or a scruple of common pitch may be taken at bedtime in the form of pills of gum arabic. A confection of hemlock (Hemlock virginian) are also useful. Amongst the milder forms of local treatment must be mentioned (1) the injection of the rectum with cold water both before and after the motion; (2) washing the anus with yellow soap and water after each evacuation—this should never be omitted by any one who suffers from piles; (3) the application of gall ointment or of other astringents; and (4) the injection of astrigent lotions, as, for instance, of sulphate of iron, in the proportion of a grain to an ounce of water. When the piles are inflamed, balsams to the anus (but not applied directly to the tumours) are sometimes required; but the inflammation generally subsides under the influence of rest in the horizontal position, fomentations, poultices, and low diet. In severe and prolonged cases operations may be necessary between the external piles removal with scissors is usually employed. In certain forms of internal piles the application of castor-oil, especially niter acid, sometimes suffices. Where their removal is required it may be effected either by ligature or by cauterisation.

The treatment of the hemorrhage which frequently accompanies piles requires a few words. If the bleeding is moderate in quantity, and has continued for some time without inducing weakness or any other bad symptom, it is not expedient to interfere with it. When, however, it obviously requires checking, the effect of cold water injected into the rectum, as already recommended, should be tried, and, in case of its failing, astrigent injections should be had recourse to. At the same time the patient should remain in the horizontal position, and take a few of the medicines prescribed for internal hemorrhage, amongst which may be especially mentioned witch-hazel, oil of turpentine, in doses of twenty drops three or four times a day, or ergot of rye in divided doses to the extent of a drachm daily. In rare cases it is necessary to perform a Gonorrhoea, or red-hot wire (through the speculum), or to bring the anus.

Pileus (Lat., ‘a hat’), the upper expanded portion of many fungi (q.v.).

Pilewort. See Ranunculus.

Pilgrim (Ital., pellegrino, Lat. peregrinus, ‘a visitor of foreign lands’). A pilgrim is one who visits, with religious intent, some place reputed to possess especial holiness. The early Christians, like the Jews and the pagan Gentiles, regarded certain places with special religious interest; above all, the Holy Land, and particularly the scenes of the Passion and Resurrection. Our Lord refers the practice of visiting Jerusalem to the discovery of the Holy Cross by St Helen. He himself was a zealous pilgrim; and throughout the 4th, 5th, and 6th centuries pilgrims habitually undertook the long and perilous journey to the Holy Land from almost every part of the world. Other sacred places, too, were held to be fit objects of the same visits of religious veneration. The tombs of the apostles Peter and Paul, and of the martyrs in the catacombs at Rome, are so described by St Jerome. St Basil speaks in the same terms of the tomb of the Forty Martyrs; and the historian Theodoret tells of not only visiting such sanctuaries, but of hanging up therein, as offerings, gold and silver ornaments, and even models of hands, feet, eyes, &c., in commemoration of the cure of diseases supernaturally obtained as the fruit of these pious visits. The Pilgrimage, however, pre-eminent so called, was that of the Holy Land; and, even after Jerusalem had been occupied by the Saracens, the liberty of pilgrimage, on payment of a tax, was formally secured by treaty; and it was from the necessity of protecting pilgrims from outrage that the kings of western Christendom undertook to maintain it. The Crusades may be regarded as a pilgrimage on a great scale; the direct object being to secure for the Latin Christians immunity of pilgrimage. On the other hand, the final abandonment of the Crusades led to a great extension of what may be called domestic pilgrimage, and drew into religious notice and veneration many shrines in Europe, which, after the lapse of time, became celebrated places of pious resort. The chief places of pilgrimage in the West were, in Italy—Rome, Loreto and Assisi; in Spain—Compostella, Guadalupe, Menestir; in France—Fourvière at Lyons (q.v.), St Denis; in Germany—Mariazell, Cologne, Trèves; in Switzerland— Einsiedeln; in England—Walsingham, Canterbury, and many others of minor note; in Scotland—Whithorn, Whithorn (near Dumfries, K. Yorks); Musselburgh, Stowe, Dunedee, Paisley, and Melrose; in Ireland, Lough Derg (q.v.), and many places connected with the life or death of the early Irish saints. The pilgrimage commonly bounded itself only by a temporary vow (differing in this from the vows of the early Christians), terminated at the place of pilgrimage, or at least with the return home, and by which he was bound for the time to chastity and to certain other ascetic observances. The costume consisted of a black or gray girdle, girl with a cincture, from which a shelf and scrip were suspended, a broad hat, ornamented with
scallop-shells, and a long staff. Many abuses arose out of these pilgrimages, the popular notions regarding which may be gathered—although, probably, with a dash of caricature—from Chaucer’s Canterbury Tales, and from Erasmus’s account of the pilgrimage to Walsingham (Peregrinatio religiosis ergo). Pilgrimages have gone much into disuse in France since the Revolution. In later days, however, pilgrims have assembled in large numbers, not only to the ancient sanctuaries of Fourvières, Puy, &c., but also to La Salette, Paray-le-Monial, and since 1858 to Lourdes. There were special pilgrimages by English Catholics to Pontigny (1874), Holy Island (1887), and Lourdes (1888). Knock (q.v.) has become a favourite Calenilar place for the Irish, the English, and the German. In 1874, 15,363 pilgrims were received, and in 1877, 15,110 came. TheDrawing of Knock is by Mr. John Brown (1805) and E. Arber (1897).

**Pilgrimage of Grace**

In their favourite Calenilar place for the Irish, the English, and the German. In 1874, 15,363 pilgrims were received, and in 1877, 15,110 came. The Drawing of Knock is by Mr. John Brown (1805) and E. Arber (1897).

**Pilgrim Fathers**, the first English colony which settled in Massachusetts (q.v.). The company, numbering one hundred men, women, and children, set sail from Plymouth in the Mayflower on 6th September 1620, bound for the banks of the Hudson; but after a long and stormy voyage they landed (21st Dec.) on the bleak shores of Cape Cod, and founded the settlement of Plymouth (q.v.).

See Devereaux’s Pilgrims and the Anglican Church (Boston, 1888); G. F. Holt’s Pilgrims Beyond (Boston, 1888); the History of the Plymouth Plantation, reproduced from the MS.—itself restored to the U.S. in 1897—of William Bradford, the pilgrim who became governor of the colony; and books by John Brown (1805) and E. Arber (1897).

**Pilphhit**

a town in the North-West provinces of India, 50 miles N.E. of Bareilly; pop. 39,799.

**Pillar**, a detached support like a column; but its section may be of any shape, whereas the column is always round. Pillars have been used in all styles of architecture, and their forms and ornaments are usually amongst the most characteristic features of the style. The Greek and Roman pillars (or columns) are the distinguishing elements in the various orders. In Gothic architecture, also, the pillars or piers are of different forms at the various epochs of that style. In the Norman period we have plain massive pillars, square, circular, and octagonal, frequently ornamented with zigzag ornaments, spiral bands, &c., on the surface (fig. 1). As vaulting progressed, the system of breaking the plain surface of the pier, and giving to each portion of the vaulting a separate little column or shaft to support it, was introduced. This was done either by attaching shafts to the pillars, or by cutting nooks in the pillars and setting little shafts in them, thus: a, b, fig. 2. In the Early Pointed style a plain circular or octagonal pillar, with a number of small shafts attached around it, is a favourite arrangement, thus: c, d, fig. 2. In this style the attached shafts are very frequently banded to the main pillar at different heights, and they are sometimes made of a finer material, such as Purbeck marble. In the Decorated style the pillar is of a lozenge form, and not so much ornamented with detached shafts as with pilasters; plain, circular, or octagonal pillars, however, are used in this, as in all the styles. The mouldings and shafts are usually filleted; and some of the mouldings run up into the arch without any cap. In Perpendicular the same idea is further carried out; the mouldings become thinner, and are more frequently run up into the arch without caps. See Flamboyant.

**Pillar-saints**, an English rendering of the Greek stylites, the name of a class of hermit-ascetics, chiefly Syrian, who crucified the flesh by living on the summit of pillars in the open air. The most noted was Simeon called Styliiates (q.v.).
PILLAU

Pillau, a Prussian town and fortress of the third rank on a spit of land at the entrance of the Frisches Haff, 30 miles W. of Königsberg by rail. Pop. 5454.

Pillitz, the ordinary summer residence of the royal family of Saxony, in a beautiful situation on the Elbe, 5 miles S. of Dresden. The palace embraces detached buildings or 'castles,' and is surrounded with beautiful parks and gardens. Here, in August 1791, the Declaration of Pillitz was framed, according to which Austria and Prussia agreed to take common action on behalf of the royal family of France against the Revolutionary

Pillory, an engine for the public punishment of criminals, disseased in Britain since 1837, but previous to that time commonly employed, as it also was in France and Germany. It consisted of a stout plank fixed like a signboard on the top of a pole, the pole being supported on a wooden platform elevated above the ground. Above, and parallel to this plank, another of like dimensions was placed in a similar position with respect to the pole, and fixed to the former by a hinge, being thus capable of being moved upwards from it, or closed upon it, when necessary. A large circular hole was made in the middle of each of the two planks, and two corresponding holes of smaller size were formed, one on each side of it; the large hole was for receiving the neck, and the two smaller the wrists. When a criminal was to be placed in the pillory he was made to mount and stand upon the platform; the upper part of the two sign planks was raised to allow the culprit's neck and wrists to be inserted in their proper grooves, and then brought down into its place, and fastened by a padlock, or in some other way. The pillory seems to have existed in England before the Conquest, in the form of the stretch-neck (an instrument by which the neck only was confined), and was originally intended, according to the 'Statute of the Pillory' (51 Hen. III. chap. 6), for persons guilty of forestalling and regrating, using deceitful weights and measures, perjury, &c. Its variety and colloquiality led to this class of offenders till 1632, when restrictions were put upon the press, and all who printed books without a license were put in the pillory. From this time it became the favourite mode of punishing libellers against the government, and many eminent men were made to wear it, among them Leighton, Liburn and Warton the printers, Pryme, Dr Lastwick, and Daniel Defoe. These sufferers were popular favourites, and the encouragement, applause, and sympathy of the crowd around converted the intended punishment into a triumph; but such men as Titus Oates, and the class of offenders including perjurers, swindlers, polygamists, &c., who were objects of popular hatred and disgust, were pelted with rotten eggs, garbage, mud, sometimes even with more dangerous missiles. In 1757 the preacher Thomas Evans was pilloried for singing a seditions Welsh song; so too, in May 1812 was Eaton, the publisher of Paine's Age of Reason; and in 1814 the celebrated naval hero Lord Cochrane, afterwards Earl of Dundonald, was sentenced to stand an hour in the pillory, but in the latter case the government did not dare to execute the sentence. The punishment was abolished for all offenses save perjury in 1815; and the perjurer Peter James Rosey was the last to stand in the London pillory, in the Old Bailey, for one hour, on 224 June 1830. In France the pillory was long ago called 'carrée' (a word of unknown origin), and in recent times carrée, from the iron collar by which the criminal's neck was attached to the post; and even so late as 1840 a woman who had poisoned her husband was at least sentenced to the pillory at Tulle as part of her punishment.

See Douce's Illustrations of Shakespeare, Griffith's Chronicles of Newgate, Andrews' Punishments in the Olden Times, and Jewitt in the Reliquary for April 1861. See also JOUGS, CANE, STOCKS, and STOOL OF REPEREANCE.

Pills are the most generally convenient and popular of all forms of medicine. They are formed from mixtures of the most convenient shape, and yet not so hard as to be of too difficult solution in the stomach and intestines. This form is especially suitable for (1) all remedies which operate in small doses, as metallic salts; (2) those which are designed to act slowly and gradually, as certain alteratives; (3) those which are too readily soluble when exhibited in other forms; (4) substances whose operation it is desirable to retard until they have reached the lower intestines, as in certain pills for habitual constiveness; (5) bodies whose specific gravities are too inconsiderable to allow their suspension in aqueous vehicles; and (6) solid substances: while it is unsuitable for (1) medicines which require to be given in large doses; (2) dysequivalent salts; (3) fluid or semi-fluid substances, such as oils, balsams, &c., which require a very large proportion of vehicle to make them sufficiently tenacious to form into a mass; (4) substances so insoluble that when exhibited in solid form they pass through the intestinal canal unaltered, as extract of logwood. Many substances, such as vegetable extracts, may be at once formed into pills without any addition; but most substances require the addition of a material termed an excipient for converting it into a pill-mass. The excipients in most common use are bread crumbs, hard soap, extract of liquorice, mucilage, syrup, treacle, honey, castor-oil, and conserve of roses. From the property of preserving pills for a long time in a properly soft state the most valuable excipient is the conserve of red roses; and, perhaps, next to it treacle is the most valuable excipient, as it does not undergo any change by time, but maintains its proper consistence, and preserves the properties of the ingredients of the pill. It is common to place pills in some fine powder to prevent them from sticking to each other, and to conceal their taste. For this purpose liquorice powder, wheat-flour, starch, and magnesia are generally used in Britain, and lecypodium or the aloe, which are continually in use, and activity far longer in small bottles than in the ordinary pasteboard boxes. The ordinary weight of a pill is five grains; if it much exceeds that weight it is too bulky to swallow conveniently if consisting of vegetable matter. It is very common to meet with patients who express their inability to take this form of medicine. If, however, they practise with a small globular mass towards which they feel no repugnance, as a pellet of bread or a currant, placing it on the back of the tongue and gulping it down with water, they will soon get over their objection.

To many people the taste of pills is a great deterrent, and various methods of coating the pills are resorted to for their benefit. Formerly coating with gold or silver leaf or with a little boul resin dissolved in chloroform were the only methods, but more recently the gelatin tablets, and pearled tablets have been prepared in vast quantities and have become very popular. There is, however, always a risk of the deterioration of such pills, owing to the length of time which they may be kept before being sold. See also QUACK DOCTORS.

Pilocarpine. See JABORANDI.
Pilot is a person specially deputed to take charge of a ship while passing through a particular sea, reach, or dangerous channel, or from or into a port. Pilots are of three classes—(1) those licensed to act in districts where the pilotage is compulsory; (2) those licensed to act where the pilotage is not compulsory; (3) unlicensed pilots. British pilots are licensed by the Trinity Houses of London, Hull, Newcastle-on-Tyne, and Leith, and by Pilotage Commissioners in other ports. The British pilotage laws were consolidated by 6 Geo. IV. chap. 125 and in 1853, but extensive changes were made by the Merchant Shipping Act of 1855, part v., and minor changes in 1862, 1872, 1874, and 1889. By the last of these acts the monopoly of employment claimed by licensed pilots has been strengthened. The scale of pilotage fees paid by the ship depends upon the distance piloted and the ship's draught of water. The fees earned are sometimes retained by the pilot earning them, less deductions for collection, superannuation, sick, or widows' funds, and sometimes they are thrown into a joint stock.

In the United States the several states make their own pilotage laws, which generally provide for the appointment of commissioners with power to make all needful rules and regulations.

A British pilot must have the conspicuously painted upon it his number, owner's name, and the port to which it belongs, and must show a large flag of two horizontal stripes, the upper white and the lower red. At night a pilot-boat on its station shows a white light, and in addition shows a flare at intervals not exceeding fifteen minutes. Shipmasters or mates are often licensed to act as pilots for their own vessels.

By British law no owner or master of any ship is answerable to any person whatever for any loss or damage occasioned by the fault of any qualified—i.e., licensed—pilot acting in charge of such ship, within any district where the employment of such pilot is compulsory by law, but this law is not international nor universal. In general, foreign nations are more stringent than Britain in excluding aliens from their pilotage services for military reasons.

Pilot-fish (Neurates duetera), a well-known fish which accompanies sharks and follows ships. It usually keeps to the open sea, and is very widely distributed in tropical and temperate regions. From the Mediterranean it sometimes follows ships to British coasts. In length it is about a foot, in shape like a mackerel, in colour variable, though generally graysish blue with five transverse dark blue bands. The first dorsal fin is represented by a few spines. Its zoological position is beside the horse-mackerels in the family Carangidae.

Many wonderful stories are told about the pilot-fish, which seems to be the Pampus of the ancients. It is said to guide the shark to its prey—nay, more, to show sailors their desired course. It certainly is a very frequent companion of the shark, especially if that fish be swimming alone, but the precise nature of the association is doubtful. The pilot-fish probably follows the shark as it follows a ship for the sake of scraps of food, and perhaps the parasitic crab, &c. With which the skin of the shark is often infested. Moreover, companionship with the shark probably protects the pilot-fish from its enemies.

Pilots. Karl von, head of the new Munich school of painters, was born in that city on 1st October 1826, studied at its academy, and sat at the feet of Schmor and Sehorn and the modern French and Belgians masters. In 1865 he was appointed professor of Painting at the Munich Academy, and in 1874 succeeded Kaulbach as director of the same. He died in his native city on 21st July 1886. All his best pictures belong to the class of historical genre; several of them are the prototypes of art built by the Bavarian kings at their capital, as the Maximilians and the New Pinakothek. Piloty was a pronounced realist; he strove to reproduce nature exactly, even to the minutest details, but did not steer clear of the dangers that attend the effort to carry out the most rigid principles to their most rigorous conclusions. He distorts the relative importance of essentials and subordinate details, and, in spite of his skill as a portraitist, his pictures frequently have a theatrical air. His drawing was strictly objective; he showed the more freedom in the choice of subject and in the employment of colour. Most of his pictures have melancholy subjects and a pathetic effect or sad background; amongst the best of them may be quoted 'Semi beside the Body of Wallenstein,' 'Nero amid the Flames of Rome,' 'Wallenstein's March upon Eger,' 'Galilei in Prison,' 'Columbus,' 'Death of Caesar,' 'Announcement of the Sentence of Death to Mary Stuart,' 'Thusnelda in the Triumph of Germanics,' and 'Death of Alexander the Great.' Piloty was an excellent teacher, his principal endeavour being to develop the individual genius of his pupils, amongst whom were Makart, Defregger, Lenbach, Max, Dietz, and others. See the Art Journal for 1865; Mrs Howitt-Watts' Art-student in Munich (2d ed. 1879); and Rosenberg, Die Münchner Maler schule (1887).

Pilpay. See Bipal.

Pilsen, the second town of Bohemia, situated in a fertile and beautiful valley, 67 miles by rail SW. of Prague. There are numerous active industries, producing building materials, machinery, metal-work, porcelain, spirits, liqueur, leather, &c. In the neighbourhood are mines of iron, alum, vitriol, coal, and sulphuric acid. But the town is most widely known from giving its name to the most approved kind of Bohemian beer, which is brewed to the extent of 9 million gallons a year, and (whether made there or elsewhere) is now largely imported into Britain. The town was stormed by Ziska in the Hussite war and by Count Malsfeld in the Thirty Years' War (1618); it was Wallenstein's headquarters in 1633-34. Pop. (1880) 38,883; (1890) 50,093.

Pimento, also called Allspice or Jamaica Pepper, a well-known spice, the dried fruit of Eugenia Pimento, a small West Indian tree chiefly confined to St. Vincent, which grows to the height of 20 or 30 feet, and has oblong or oval leaves about 4 inches long, of a deep shining green, and numerous axillary and terminal trichotomous panicles of white flowers, followed by small dark purple berries. The pimento-tree is cultivated in some of the West Indian islands. It is a very beautiful tree, with straight white trunk and much-branching head; about the month of April it is covered with an exuberance of flowers, which diffuse a rich aromatic odour. The leaves
and bark partake of the aromatic property for which the fruit is valued. The fruit, when ripe, is filled with a sweet pulp, and the aromatic property which so strongly characterises it in an unripe state has in a great measure disappeared. The gathering of the berries, therefore, takes place as soon as they are full size, when the blossoms are shed and the parch of peppers are gathered by the hand, and dried in the sun on terraced floors, during which process great care is taken, by turning and winnowing, to prevent them from being injured by moisture. Their colour changes in drying from green to red. Bushel boxes of dried pimento are packed in bags for the market. Some planters kiln-dry them. The name Allspice was given to pimento from a supposed resemblance in flavour to a mixture of cinnamon, nutmeg, and cloves.

Pimento is much employed in cookery, and is also used in medicine as a carminative and stimulant to prevent the griping of purgatives, and to disguise the taste of nauseous drugs. It depends for its properties chiefly on a volatile oil, Oil of Pimento, which is obtained from it by distillation with water, and is sometimes used to relieve toothache. The leaves, stems, and berries, when carried on in young shoots of the tree. From 3000 to 4000 bundles (500 to 500 in each bundle) are shipped annually from Jamaica for sticks for umbrellas. The crop of pimento in Jamaica, which alone furnishes the spice to commerce, varies. In 1888 it was 60,550 cwt, and in 1889, 46,179 cwt. The average receipts of the spice in England are about 4,000,000 lb.

Pimpernel (Anagallis), a genus of elegant little annual and perennial plants of the natural order Primulaceae, natives chiefly of temperate climates. They have a wheel-shaped corolla, and the capsule is divided into five, as in the midday, or mimicry. The flowers are not large, but very beautiful. Those of the Scarlet Pimpernel (A. arvensis), common in most parts of Europe and many parts of Asia, and occurring in Britain as weeds in the fields and gardens, are of a fine scarlet colour, with a purple circle at the eye. They usually open about eight in the morning and close about noon. In the common belief, mentioned by Lord Bacon, their opening in the morning presages a fine day; while they certainly close very readily upon the approach of rain—whence the popular names in some places of Poor Man's Weather-glass and Shepherds's Barometer. The Blue Pimpernel (A. caerulea) is far less common in Britain, but very abundant in some parts of Europe. The Bog Pimpernel (A. tenella), frequent in bags in England, but rare in Scotland, is an exquisitely beautiful plant. Several species are cultivated in flower-gardens. Acid properties prevail in this genus, and A. arvensis has been used medicinally in epilepsy, dropsy, and mania. The name Water Pimpernel is given to Samolus valerandi, also called Brookweed, another British plant of the same order, with racemes of small white flowers, growing in wady or gravelly places. It is supposed to be the Samolus which Phiny says the Druids gathered fasting, with the left hand, and without looking at it, ascribing to it magical virtues in the cure and prevention of diseases in cattle. Its geographical distribution extends over Europe and Asia.

Pinar del Rio, a city of Cuba, 95 miles direct W.S.W. of Havana, with which it is connected by rail, and about 14 miles from Colonna, its port, on the south coast. It is the centre of the famous 'Vuelta Abajo' tobacco region, and trades in tobacco. Pop. (1899) 8880; of the province, 173,934.

Pimples. See PAPULES, ACNE, PUSTULES.

Pin. See PINS.

Pina Cloth, a beautiful fabric made of the fibres of the leaves of the pine-apple plant. See FIBROUS SUBSTANCES, BROWELLACE.

Pincbeck, a reddish-yellow alloy of zinc and copper, containing 4 parts of copper to 1 of zinc. It was invented by Christopher Pincbeck, a London clockmaker, who died in 1732, and was much employed at the beginning of the 19th century for making watch-cases and other small articles in imitation of gold. The term is now but little used.

Pindar, Charles Cotesworth, an American statesman, was born at Charleston, South Carolina, 25th February 1746, was sent to England and educated at Westminster and at Christ Church, Oxford, read law at the Middle Temple, and studied for a while at the military academy in Caen. He afterwards sailed as a barrack reader at Charleston. He was Washington's aide-de-camp at the battles of Brandywine and Germantown, and afterwards, as colonel, saw much active service, until 1780, when he was taken prisoner at the surrender of Charleston, and detained till called for in the peace of 1783. A member of the convention that framed the constitution of the United States (1787), he introduced the clause forbidding religious tests as a qualification for office. He declined the secretaryship of war in 1784, and of state in 1785; in 1790 he was sent as minister to France, but the Directory refused to receive him, and he returned to quit the country. It was while on this mission that, when it was intimated that peace might be granted in return for a money payment, he replied, 'Millions for defence, but not a cent for tribute.' He was unsuccessful in 1800 as Federalist candidate for the vice-presidency, and in 1804-8 for the presidency. He died 16th August 1825.

Pindar (Gr. Pindaros), the chief lyric poet of Greece, was born about 522 B.C., of Thesan family at Cynocephalides, near Thebes, the capital of Boeotia, a district in which music and poetry were widely cultivated. His family, the Ageidei, was an old and illustrious one, often mentioned in the heroic legends. His father or his uncle was a flute-player, and Pindar inherited the musical talent of his family. He made music and poetry his profession, and was placed under the tuition of Lasus, a well-known musician and poet, at Athens. Thothes was the bitter foe of that city, Pindar often speaks of Athens with love and admiration, but he is to have been influenced far more deeply by Corinna and Myrtis, two poetesses then famous, with whom he competed for the prize at public contests. Corinna five times gained the victory over him. She assisted the young poet with her advice, judiciously as it would seem. It is said that she urged him to introduce mythical subjects into his poems, and then, when he had composed an ode introducing almost the whole Thelian mythology in the first six verses, she smiled and said: 'We ought to saw with the hand, and not with the whole sack.' He recommenced his career of composition for special occasions at the early age of twenty with a song of victory which still remains (Pyth. X., composed in 502). He soon reached the highest rank in his profession, and composed odes for persons in all parts of the Greek world. He was employed by his kinsman, the Sicilian ruler, Hiero II., and Thero of Agrigentum, by Arseleus of Cyrene and Amyntus of Macedon, as well as by the free cities of Greece. Wherever he went, he was honoured and loved for his own sake as well as for his art. State dinner with one another in doing him honour, and the cities like Athens and Piraeus made him their public guest. Though a frequenter of princely houses and king's palaces, he never lost his independence. In his poems he gives advice and reproof as well as praise to his patrons. He warns
the great Hierof to avoid flatterers, and cantions Areoslaus of Cyrene against undue severity. He resided four years at the court of Hiero. He died about the age of eighty in 443 B.C. Two conquerors—Panamis, king of Sparta during the Peloponnesian war, and later Alexander the Great, who held the court of Hiero, stood together in Thebes standing—spared the house of Pindar.

Pindar was in the prime of life when Salamis and Thermopylae were fought, when Greek energy and enterprise were at their highest, and Greek poetry and philosophy were opening into their rich field. This was to his people not an old rather than the new period of literature. In spite of his admiration for Athens, which he calls 'the pillar of Greece,' the spirit of Athens did not lay hold of him. Intellectually, he stands nearer to the age of Homer than to that of his contemporary Eschylus. Pindar's language is Epic, tinged with Doric. He wrote an immense number of poems, including hymns to the gods, pears, dithyrambs, odes for processions (prosodia), mimic dancing songs (hyperoochenaia), chorical songs of maidens (parthenoeis), convivial songs (sakoi), dirges of fallen heroes, and odes in praise of the victors (encomiai). Of all these poems we possess fragments only, often very beautiful, but his Epinikia or Triumphal Odes have come down to us entire. They are divided into four books, celebrating the victory of the Olympic, Pythian, Nemean, and Isthmian games. The special occasion for which these odes were composed explains their character. A victory won either in the chariot-race, for prowess in wrestling or other exercises, or for skill in music was the subject of another song, to which he also added a victory to the winner and his family, but also on his city, and received a solemn celebration. It began with a procession to the temple, where sacrifice was offered, followed by a banquet, and concluding with a boisterous revel (zomia). Thus the festival was partly religious, partly convivial and jocose. For the occasion an ode was composed, and was sung by a chorus either during the procession or, more frequently, at the banquet. An intense enthusiasm for athletic sports was one of the most distinctive features of Greece, and, as of the Greek national character. The performance of a triumphal ode by a trained choir to the music of lyre and flute, amid an enthusiastic concourse of the victor's townsman, must have been one of the most stirring events of Greek civic life. Pindar not as a mere poet of athletic triumphs, but as connected with the victor's whole life and history. He loves to dwell on the moral side of it, not merely on the bodily prowess which gained it, but on the temperament, love to parents, or piety which secured the favour of the gods who granted success. And this is to him no mere poetic fiction, for he has the sincerest faith in the divine superintendence. But it is too much to say, as Paley does (Trans. Pref. p. viii.), that Pindar shows 'unquestioning creulity in the wildest legends.' Of myths relating things unworthy of the gods he says he cannot understand 'such visions of the divine beings!' (as of the myth of Pelops, Od. i., and another regarding Herakles, Od. ix.). The plan of his poetry is intricate, and the connection of the different parts is often very hard to see. Pindar is deeply skilled in trains of thought, either relating to the victor, his ancestors, the history of his city, or else moral reflection; he breaks off each of these before the application is seen, and it is not till the end of the poem that he weaves the different threads together and explains the allusions. Thus, says Miller, 'the curiosity of the reader is kept on the stretch throughout the entire ode.' The great merit of Pindar's poetry is its vivdness and picturesque power, seen even in single epithets, as when he calls the mountain-mass of Etna, overtopping all heights in the island, 'the forehead of fertile Siciy.' It is this vigour and vividness which suggest Mrs Browning's picture of 'bold, electric Pindar . . . with race-dust on his cheeks,' and urges that some of his odes should be sung as his last goal. The description of the happy lot of the good after the final judgment in the Islands of the Blessed (Od. ii.), the voyage of the Argonauts (Pyth. iv.), and the vivid picture of the eruption of Etna in the First Pythian Illustrate this power. He had a special gift for making his odes speak as in a mirror the intense admiration of the Greeks for bodily prowess, strength, endurance, and beauty. Such gifts rouse in him a feeling of religious veneration; they come from the gods and are sacred. The groundwork of Pindar's poems consists in those legends well known from the Greek religious literature. It will be seen that his life was intimately associated with the observances of Greek religion. In connection with the worship at Delphi he received unique honours. The belief in his divine inspiration existed from the first itself in the legend, which apparently sprang up during his life, that the god Pan was seen and heard in a glade between Citharodon and Helicon singing one of Pindar's hymns. When once asked what sacrifice he intended to offer at Delphi, he answered 'poetry,' and the following hymns are full of religious feeling, not formal but real. His protest against myths dishonouring to the gods shows a truly reverent nature and an enlightened belief. Both in its strength and in its deficiences his poetry reminds us of his claim on his own behalf: 'The name was wise when Homer made by natural genius;' but the poets, his rivals, 'those who have learned,' the versatile talkers, are not as rows calmly chattering against the divine bird of Zens.' Thus the distinction between genius and talent is as old as Pindar's time. This high faith in his own poetic inspiration must be the stronger for self-confidence; it also almost verges on a contempt for art which seems responsible for the frequent intricacy and obscurity of his poetry.

See Höckel (1811-21); Dassen (1830); re-edited by Schneidewin, 1851-5; see also Schneidewin's letter (1853) to the editor of Schneidewin's death (complete); Fellner (1879-83); Bury, Nemean Odes, 1891; translations by Cary in verse (1838), Paley (occasionally powerful, but arbitrary; (1850)), E. Myers (2d ed., 1883). (Muller and Dodin's History of Greek Literature is full of excellent criticism.

Pindar. See WOLCOT.

Pindar’s, or Pindarees, bands of freebooters or mercenary soldiers who, after the overthrow of the Mogul empire of India, grew (1804-17) to be a formidable power in the Central Provinces, their headquarters being at Malwa. Hastings put an end to their depredations, gathered two armies (120,000 men in all) in 1817 and crushed them.

Pind Dadan Khan, a town in the Punjab, stands one mile N. of the Jelum and 110 miles NW. of Lahore. The people (16,724) make brass and copper utensils, pottery, whips, boats, and woolens, and carry on a large trade.

Pine (Pine), a genus of trees of the natural order Coniferales. Pines are distinguished by monocious flowers, and woody cones with numerous two-seeded scales, the scales having an angular truncated apex. The leaves are linear and very narrow, growing in clusters or in pairs, and surrounded by scale-like glands at the base. To this genus belong many noble and useful trees. They mostly grow in mountainous or other exposed situations, and their narrow leaves are admirably

PINE
adapted to evade the force of winds, which produce in the tops of pines a peculiar sound, much noticed by the ancient poets, more soft and continuous than in trees of richer foliage. Most of the pines are more or less social, one kind often covering a considerable tract; some of them clothing the sides and even the summits of mountains with magnificent but sombre forests; some growing in lower situations, on otherwise unproductive sandy grounds, as the Pine Barrens of North America. The pines growing in the most barren soils, or in the coldest climates and most exposed situations, are often very small, and, although very unlike any other shrubs or bushes, are scarcely to be called trees. Pines are widely diffused over the northern hemisphere, being found on mountains within and near the tropics, and in the colder temperate and the arctic regions descending to the level of the sea.

The Scotch Pine, commonly but erroneously known as the Scotch Fir (P. sylvestris), is the only species indigenous to Britain. It has leaves in pairs, about an inch and a half long, the cones about the same length, oblong, and with unarmed scales. On very poor soils and at great elevations it is reduced to a kind of shrub, but in favourable situations it becomes a lofty tree. A plank five feet and a half in diameter has been obtained from a Scottish forest. The Scotch pine is of quick growth, but has been known to attain the age of 400 years. Its head is somewhat conical or rounded, and the lower branches die off as the tree grows, leaving the older trees bare of branches for the greater part of their height; but it is more apt to send off large branches than most of the Conifers. There are still native forests of Scotch pine at Braemar and elsewhere in the Highlands of Scotland; and even in the south of Scotland noble trees are to be seen which, probably, were not planted by man. The Scotch pine is not indigenous to the south of England, but, having been introduced, is spreading rapidly and spontaneously, along with the Pinaster, in some of the heaths and other unfertile tracts. Immense forests of it exist in some countries of Europe, in some of which it is mingled with the Spruce Fir. In the middle and north of Europe and of Asia it is found even in plains near the level of the sea, especially where the soil is somewhat sandy; in the south of Europe it grows only on mountains. Its timber is highly valuable, being very resinous and durable, and is the Red Deal or Red Pine used in house and ship carpentry. There is very great difference, however, in the timber of Scotch pine growing in different soils and situations, rich soils and sheltered situations being unfavourable to the quality of the timber, which becomes white, soft, and comparatively worthless; and there exist several varieties of Scotch pine, some of which yield timber very superior to others. Many plantations in Britain have, unfortunately, been made of inferior kinds. One of the best varieties is that which forms the northern Scottish forests, often designated Braemar Pine by nurserymen. It is remarkable for its very horizontal branches, and is therefore sometimes called P. horizontalis. The Scotch pine is not only valuable for its timber, which is available for some purpose at every stage of its growth, but on account of other products. Common Turpentine is obtained from it, and much Tar, Pitch, Resin, and Lamplack (see these heads). Oil of turpentine is sometimes distilled from the cones, and even from the leaves; the leaves have also been used for the manufacture of Pine-wood (see FABRIOUS SUBSTANCES, Vol. IV, p. 606). The resinous roots are dug out of the ground in many parts of the Highlands of Scotland, and, being divided into small splinters, are used to give light in cottages instead of candles. Fishermen, in some places, make ropes of the inner bark, which is applied to a very different use, when most soft and succulent in spring, by the Kamchatkans and Laplanders, being dried, ground, steeped in water to remove the resinous taste, and used for making a coarse kind of bread.

The Dwarf Pine (P. Pumilio) is found on the Alps and Pyrenees, its trunk often lying on the ground, although sometimes it appears as a bush or low tree. The leaves are in pairs, very like those of the Scotch pine, but a little longer; the cones

**Fig. 2.** Cones of (a) *Pinus montana*; (b) *P. pinea*; and (c) *P. Pinaster*. Cones and needles of (d) *P. crassilata*; and (e) *P. Lambertiana*. All about 1 natural size.

...are also similar. From the young shoots an oil resembling oil of turpentine is obtained by distillation, which is a kind of universal medicine among the peasantry of Hungary, as is also the resin spontaneously exuding from the tree, which is known as Hungarian Balsam. The Black or Austrian Pine, or Black Fir (*P. nigra*), or *P. austriaca*,
another species closely allied to the Scotch pine, but remarkable for its very long leaves. It is a native of Austria. It abounds in resin more than any other European tree. To the same group of pines belongs the Seaside or Taurian Pine (P. /alliata, maritima, or tarriaca), which also abounds in resin; and the Scotch, or Canadian, is a very handsome and pleasant odour. It is found in many parts of the south of Europe. Its timber is of little value; but great part of the turpentine of the Landes and other maritime districts of France is obtained from it. It yields also part of the Eucalyptus Pitch of the southern States, the tree called Juniper, (Juniperus halepensis), a native of the south of Europe, Syria, &c., is a very graceful tree of moderate size, with leaves in pairs and slender. It yields a liquid resin or turpentine, which is extracted from it in Providence and elsewhere, and sold as Venetian Turpentine. The wood is extensively used in the Levant for shipbuilding. The Laricio (P. Laricio) has leaves in pairs, lax, and 4 to 8 inches long, cones 2 to 4 inches long, with the scales slightly pointed. It is often called the Corsican Pine. It grows in the plains of that region, and is valuable both for its timber and for its resinous products. In the island of Corsica it frequently attains the height of 140 feet. It grows well in sandy soils, and has been made particularly useful for preventing the drifting of the sand, and turning to timber the unproductive portions of the shore. The months of the Garonne and the Adour in France, thus also preserving valuable lands which the sand threatened to overwhelm. The Pinaster or Cluster Pine (P. Pinaster) is another of the most important European species. It has cones in whorls of 3, 4, or 5, in length 4 to 6 inches long, with the scales rounded, in pairs, and very long. It is found on the shores of the Mediterranean, and also in the Himalayas and in China. It has been used in France to a great extent, in the same way as the Laricio, for covering waste sandy tracts. The timber is of inferior quality, but great quantities of resin are procured from it. It yields Bordeaux Turpentine. The Pyrenean Pine (P. pyrenaicus) is a majestic tree, a native of the Pyrenees, and producing very fine timber. The Calabrian Pine (P. brutia) somewhat resembles the Pinaster. The Turkish Pine (P. pinea), a tree with a broad umbrella-shaped crown, and a form often seen also in the Scotch fir, forms a characteristic feature of the scenery of the Mediterranean. It is the Pinie of the Germans, the Pignau of the French. The leaves are in pairs, 4 to 5 inches long, the cones very large, ovate, and obtuse. The seeds, which do not ripen till the fourth year, are large, abound in a fixed oil, and when fresh, have a sweet taste resembling that of almonds. They are used in Italy and other countries in the same way as almonds and pistachio nuts for the dessert, in various dishes, also in emulsions, &c., under the names of pinias, pinioles, and pignons. The use of them, however, is almost entirely confined to the countries in which they are produced, as they very soon become rancid. They are sometimes imported into London in the cabin in long vessels, 6 to 8 inches long, but here the cost of importation is much increased. The wood of this tree is very useful and beautiful. It yields resinous products only in small quantity. The Cembra Pine, or Swiss Stone Pine, with its cones in the central parts of Europe and the south of Siberia—a stately tree, with the lower branches more persistent than they are in most pines, and rigid leaves in groups of three to five— also produces edible seeds (Cembra Nuts). The Cembra Pine yields a pellicent, whitish oil, resembling that of turpentine, and known as Carpathian Balsam.

North America produces many species of pine, some of them very beautiful and very valuable. Besides those long known, and which are found in the states and colonies near the Atlantic, a number of the noblest species of this genus have, since the commencement of the 19th century, been discovered in California and the north-western parts of the United States. The Weymouth Pine, discovered in the autumn of 1850, is found from Canada to the Pacific, but does not reach far south in the United States. It is the Yellow Pine of California and Nova Scotia. It delights in dry and sandy soils, and attains a height of 80 to 90 feet, with a diameter of 2 feet at the base, the tree is stately, and is thinned for two or three of its length. The leaves are in pairs, and are congregated towards the extremities of the branches. The timber is highly esteemed for strength and durability, and furnishes excellent planks for shipbuilding. It is also used for masts. Some of the other species mentioned above, such as the Spider Pine, or Gray Pin (P. Banksiana), generally only 3 to 10 feet high, which begins to appear in the northern parts of the United States upon high mountains, and is interesting as an American species, is mentioned by another name. The Yellow Pine (P. variabilis, or P. millos) abounds in the Atlantic states from North Carolina to Virginia. It is a tree 50 to 60 feet high, 15 to 18 inches in diameter at the base, with leaves 4 to 5 inches long, usually in pairs, but sometimes in threes, produced on the younger branches. Its wood is very extensive used for shipbuilding, and is largely exported to Great Britain. At Liverpool it is known as New York Pine. The Jersey Pine, or Scrub Pine (P. nigra), abounds in the lower parts of New Jersey, and thence to the south-west. The trees attain great heights, 1 to 2 inches long, the cones armed with strong spines. The tree is rarely 30 or 40 feet high. Great quantities of tar are made from it in Kentucky. The Pitch Pine (P. rigida) is a native of the northern and middle parts of the United States, often growing in great mazy swamps, and attaining a height of 40 to 80 feet, and a diameter of 2 feet at the base. The leaves are in threes, varying much in length, as the cones do in size. Immense quantities of it are used for fuel. Tar and lampblack are sometimes made from it. The Loblolly or Old Pine (P. abies), grows in dry and sandy soils, and is employed in the southern states, often occupying lands exhausted by cultivation. Vast tracts never cultivated in the southern states are Pine Barrens, in great part covered with this species of pine. It attains a height of 80 to 100 feet, and upwards, and has a wide spreading crown. The leaves are 6 inches long, in threes, sometimes in fours on young branches, the cones 4 inches high, with strong spines. The timber is not of much value. The Long-leaved Pine, or Southern Pine (P. palustris, or P. australis), is perhaps the most important of North American forest trees. It furnishes the greatest part of the tar, resin, pitch, and turpentine used in the United States. The timber is also very valuable, and is much used for shipbuilding. In England and the West Indies it is known as Georgia Pitch Pine. The tree attains a height of 60 to 70 feet, and a diameter of about 16 to 18 inches; the leaves are in threes, and about a foot long, the cones 6 to 8 inches long, and 4 inches in diameter, with small spines. The seeds are sometimes eaten. The White Pine (P. strobus) is a native of New England and the Weymouth Pine, from its having been largely planted by Lord Weymouth, attains a height of 150 feet, and a diameter of 5 feet and upwards. It has lax sub-triangular leaves in groups of five, and pendulous cones 4 to 5 inches long, with thin smooth scaling, and a fresher odour, and is cultivated on the continent of Europe for its beauty. In its native country it abounds chiefly from lat. 47°
to lat. 43°, and southward to the Alleghanies. The timber is not strong, but easily wrought and durable. Of the species belonging to the northern United States, the most magnificent is _P. lambertiana_, which is found on the Rocky Mountains between lat. 40° and lat. 43°, chiefly on sandy soils. It attains a height of 150 to 200 feet, and a diameter of 7 feet and upwards, almost to 20 feet. The trunk is remarkably straight, and the branches for two-thirds of its height; the leaves in fives, the cones upwards of a foot long. The timber is white, soft, and light; and the tree produces great quantities of a pure amber-coloured resin, which, when the wood is partly burned, is changed into a substance of a rich golden colour, used by the Indians as a substitute for sugar. The seeds are eaten either roasted or pounded into coarse cakes. _P. flexilis_ is found on the Rocky Mountains, near the head-waters of the Arkansas, and occurs almost to the limit of perpetual snow. It has a dense crown formed of numerous and remarkably flexible branches. The leaves are in fives. The seeds are used as food by hunters and Indians. _P. ponderosa_, another native of the Rocky Mountains, is a magnificent tree, remarkable for the hardness of its timber, which almost sinks in water. The leaves have ten rays, and the cones 14 inches long. *P. sabiniina, P. coulteri*, and _P. tussigina_ are also noble species from the west of North America.

The Himalayas abound in pines, some of which rival in magnificence those of North-west America. The Bhutan Pine (_P. exelsa_), much resembling the Weymouth Pine in its botanical characters, and attaining a height of 90 to 120 feet, abounds in Bhutan, although it is not found in the neighbouring countries of Sikkim and Nepal. The wood is highly valuable, being durable, close-grained, and so resinous as to be used for flannel, and candles. The Cheer Pine (_P. longifolia_) of India is a tree of remarkable and most graceful appearance, with leaves in threes, very long, very slender, and generally pendulous. It is abundant on the crests of hills in the lower Himalayas, growing at a height of 8,000 feet. The threes are cultivated in some parts of India as an ornamental tree. It is much valued for its resin. The wood is used in India as a substitute for European deal. The Khassa Pine (_P. khassiana_) is peculiar to the Khasia Mountains, and has commercial application. The tree is a large one, the cones of the third kind. _P. gerardiana_, a species with leaves in threes, is a large tree, a native of Nepal. The seeds are fertile. The mountains of India and the north-western parts of America produce numerous other species; Mexico has a number of very fine ones peculiar to itself; the mountains of St Domingo have one; the Canary Islands have one; China and Japan also have some. Most of those which have been named, and a number of others, are now readily to be procured in nurseries in Britain, although some of them only at prices which prevent any attempt at extensive plantation. Some wealthy noblemen and gentlemen devote a portion of their grounds to a collection of different kinds of pine, called a _Pinetum_. A few foreign species have become pretty common in plantations. Most of them thrive quite handsomely in Britain, but this is not the case with the more abundant and beautiful species of the Mexican species. The name pine is often popularly extended, and even in scientific works, to other Conifera; many trees called pine being properly treated at fir.

**PINEAL GLAND.** This term is in general use for the timber of the pine-tribe (see _Conifera_), and is not confined to that of the genus _Pinus_, but embraces the wood of species of _Abies_, _Larix_, _Araucaria_, _Dacrycarpus_, &c. From the Baltic ports come red wood and white wood. The former is yielded by the Scotch Fir (_Pinus sylvestris_), and the latter by the _Pinus strobus_. This wood is best known in America as white pine, but in Great Britain, and in commerce generally it is called yellow pine. Commercially it is the most important timber of Canada and the eastern states of America. The yellow pine of this part of America is the _Pinus mitis_, also a valuable timber-tree. The red pine (_Pinus resinosa_), found from Canada to Pennsylvania; it is intermediate for durability between white pine and pitch pine. The celebrated pitch pine of the eastern states of America is the product of _Pinus rigida_. It is used for ships' masts and yards, and for purposes requiring great strength and durability, in both of which qualities it excels most others of its kind. The kinds above mentioned are those which constitute the greater part of the pine-timber used in ship and house building, carpentry, &c. in Great Britain and the eastern side of America. The _Pinus longaeva_ of the Cordilleran (see _Cordilleran Pine_ (_Pinus Laricio_)) and the Sessile Pine (_Pinus Pinaster_) are greatly used. In Central and Southern Europe, from the pine-timber is chiefly yielded by the _Stone Pine_ (_P. pinea_) and the _Catalan Pine_ (_P. brutia_); that of Spain is from the Pyrenean Pine (_P. uncinata_). In Germany, and especially in Austria, the _Black Pine_ (_P. austrinica_) furnishes the greatest portion; but the fine-grained, soft white pine, or deal, so much used for sounding-boards of musical instruments, is the wood of the Silver Fir (see _Fir_). The trade in this timber is very great, for not only do the Germans use it almost exclusively in their vast toy manufactories and for Lucifer matches, but considerable quantities are exported. The finest is cut in the forests of Bohemia, where large establishments are formed for dressing and preparing the wood for various purposes.

Several other kinds of pine-timber are imported into Europe, but those mentioned form the great staples of the timber-trade. The chief value of this class of timber-woods is in the combination of lightness and strength with softness of texture and ease in workmanship, which makes them most serviceable for small articles. In this respect, in fact, the principal materials of European and American builders, and are used more than all other kinds of wood together. Much confusion prevails as to their common designations, for in Britain alone fir, pine, and deal are terms applied to all and each of them, according to the caprice of the individual. The first two names are used because the material is derived from one or other of those genera; but the last is a misnomer altogether, as the term deal belongs only to pieces of fir or pine timber not to particular sizes: they are 3 inches in thickness, 9 inches broad, and of variable length; if of less width, they are called _bottees_. See _TIMBER_.

**Pineal Gland.** A rounded body about the size of a pea, of a slightly yellowish colour, situated upon the anterior pair of corpora quadrigemina, and connected by a stalk passing upwards to the second, or posterior division of the third ventricle. It contains small cavities in its interior. The function of the gland has long been matter of speculation. It was regarded by Descartes as the seat of the soul. It has been recently discovered to be a part of the nervous system, consisting of a number of elements of which can be distinctly traced in some of the lower vertebrates.
Pine-apple, or Ananas (Ananassa sativa), a plant of the natural order Bromeliaceae, highly esteemed, and much cultivated for its fruit. The fruit is a *sorosis*, formed by the calyces and bracts of a close spike of flowers, becoming succulent and combined. This is the distinctive character of the genus Ananassa. The pine-apple has a number of long, serrated or smooth-edged, sharp-pointed, rigid leaves, springing from the root, in the midst of which a short flower-stem is thrown up, bearing a single spike of flowers, and therefore a single fruit. From the summit of the fruit springs a crown or tuft of small leaves, capable of becoming a new plant; the pine-apple, in cultivation, being propagated entirely by crowns and suckers, as, in a state of high cultivation, perfect seed is almost never produced. The pine-apple is a native of tropical America; it is found wild in sandy maritime districts in the north-east of South America, but it has been very much changed by cultivation. It has also been gradually diffused over tropical and sub-tropical countries, and not only as a cultivated plant, for it is fully naturalised in many parts both of Asia and Africa. It delights in a moist climate, and consequently does not succeed well in the dry climate of the south of Italy, although the warmth is sufficient. The first particular account of the pine-apple was given by Oviedo in 1535. It was in Holland that it first began to be cultivated in hothouses; but it was introduced into England from that country in 1699, and first cultivated by Mr Bentinck, ancestor to the ducal family of Portland; and its cultivation rapidly became general in the gardens of the wealthy. It is only since the peace of 1815 that it has received similar attention in continental Europe. Great care is requisite in the cultivation of the pine-apple, which without it is generally fibrous and coarse, with little sweetness or flavour, and with it one of the most delicate and richly flavoured of fruits. Its size, too, very much depends on cultivation, but there is also considerable difference in the size of the fruit in different varieties, the largest not being always the most luscious and superior in flavour. The size varies from 2½ lb. to 12 lb. in weight. The pine-apples grown in British hothouses are generally much superior to those of the West Indies, because the latter grow almost or altogether without cultivation; but the importation of pine-apples from the West Indies has now been carried on to a considerable extent, and, as it promises to add to the sources of wealth for these colonies, this has led to greater care in cultivation there, and consequent improvement of quality.

Formerly the culture of the pine-apple in Britain was a costly and extremely tedious process. Since very early after its introduction it has always been cultivated in hothouses specially appropriated to be called pine-apple houses, which were heated by smoke-flues, with tanners' bark or oak-leaves and dung for bottom heat. But by the universal adoption of hot water in horticultural heating the labour and cost attendant on those clumsy expedients have been much reduced and better results attained. Along with this there has been brought about a more rational treatment of the plants. Instead of high tropical ground and atmospheric heat being maintained in winter, which resulted in destroying the roots of the plants in the preliminary stages of their growth, and so retarded or deferred their fruiting period, the skillful pine-apple grower now finds that success is best assured by adopting a minimum of 60° of air-warmth and 75° of bottom-heat at that season. By these and other improvements in treatment superior fruit is obtained in half the time formerly considered necessary. The pine-apple is cultivated in pots or planted out in beds. It is more completely under control in pots than planted out, hence the results are always more certain when it is grown in that way. It is propagated by suckers and by the crowns that are formed at the base of the fruit when the cases of varieties which produce the former too sparingly for the requirements of stock, the latter are usually rejected because they do not make so good plants nor fruit so quickly as a rule. The varieties of the pine-apple that are worthy of being cultivated in Britain are few. For producing superior fruit in winter the Smooth Cayenne and Black Jamaicar are two of the best and most reliable, and the Queen, of which there are several sub-varieties, is the most highly esteemed for summer fruiting. Turfy, fibrous, sandy loam that has lain in a stack for nine or twelve months must be used, firm, loamy, bricks, &c. Pop. (1900) 11,496.

**Pine-apple Oil**, see BUTFYRIC ETHER.

**Pine-beetle.** See BARK-BEETLES.

**Pine Bluff,** capital of Jefferson county, Arkansas, is built on a high bluff on the south bank of the Arkansas River, about 120 miles from its mouth, and 43 miles by rail SSE. of Little Rock. It contains large ironworks, ships a good deal of cotton, manufactures much woolen stuff, and has oil, flour, lumber, bricks, &c. Pop. (1900) 8,592.

**Pine, PHILIPPE,** a Parisian physician (1745–1826) who gained for himself undying fame by his reformation of the old barbarous methods of treating the insane. See INSANITY.

**Pineo, ARTHUR WING,** born in London in 1835, studied law, but in 1854 made his début on the stage at Edinburgh, and in 1875 joined the Lyceum company. He is best known as the author of a number of successful plays, including *The Squire* (1881), *The Roquet* (1883), *Sweet Lavender* (1888), *The Second Mrs Tanqueray* (1893), and *The Notorious Mrs Ebanks* (1895).

**Pineole, or PINEGEOl,** a town of North Italy, at the east foot of the Alps, 23 miles by rail NW. of Turin. Originally a town of Savoy, it was regarded as the key of Italy. In its strong citadel, the Man with the Iron Mask, Lanzun, and Fouquet were imprisoned, and in 1674 he gave his favourite grandson his crown of gold hands from 1536 to 1574, again from 1630 to 1696, from 1704 to 1706, and from 1801 to 1814. The town contains a cathedral and a technical school. Cloth, paper, leather, cotton, and silk are manufactured. Pop. 12,093.
Pine-tree Money, silver money coined at Boston, Massachusetts, in the 17th century (from 1652), and so called from the coin's bearing the rule figure of a pine-tree on one side.

Pine-wool. See Fibrous Substances.

Pink (Dianthus), a genus of plants of the natural order Caryophyllaceae, of which there are many (some 290) species, annuals and perennials, with beautiful and often fragrant flowers, chiefly native of Europe and the temperate parts of Asia. The calyx is tubular, 5-toothed, with two or four scales at the base; there are five petals suddenly contracted at the throat of the corolla into a linear claw. There are ten stamens, and one ovary with two styles, the stigma cleft, and one- seeded. The exquisite beauty of the flowers has attracted admiration in all ages; and some of the species have long been much cultivated in gardens, particularly the Garden Pink and Carnation (q.v.), which are often referred to one original, the Clove Pink (D. Caryophyllus), a native of the south of Europe, growing wild on rocks and old walls, and naturalised in some places in the south of England; whilst some botanists refer the garden pinks with more probability in part to the Maiden Pink (D. deltoides), a pretty common British species, and a wild Dianthus pinks to the Feather Pink (D. plumarius), a native of some parts of continental Europe. The varieties of the garden pink and the pheasant-eye pink, which are usually designated the florists' pink, are of much less antiquity than the carnation as garden ornaments. Othier scarcely mention them, while in Parkinson's time they appear only to have been cultivated as other hardy perennials and annuals were, without any special care. Their capabilities as choice florists' flowers were recognised about 1810, and the number of varieties has since then greatly increased to nearly 500. Nearly all of them are species, found in moist places in some parts of Europe, and not unfrequently to be seen in flower-borders. It has very fragrant flowers. Both single and double pinks are generally propagated by sowing, which are short cuttings of the younger shoots. They also sow the seed in suitable propagating layers. A rich loamy soil is the best for pinks. The Maiden Pink is a small, much-branched plant, growing in grassy places, on gravelly and sandy soils; it has rose-coloured flowers spotted with white, and a white eye encircled by a deep purple ring. The Pink (D. purpurea) and the Clustered Pink, or Chilbing Pink (D. prolifer), also natives of England, differ from these in being annuals, and in having clustered flowers. The Bearded Pink, or Sweet William (D. barbatus), a native of the middle of Europe and the south of France, with laceolate leaves, flowers crowded in dense clusters at the top of the stem, annunated bracts, and bearded petals, has long been a favourite garden-flower, still retaining its place alike in palace and cottage gardens. Although perennial, it is sown annually by florists, to secure fine flowers, and the flowers are much admired, single and double, exhibiting much diversity of colour. The Mule Pink, or Fielding's Pink, a choice kind, is supposed to be a hybrid between the Sweet William and the Pheatee. The Indian Pink, or China Pink (D. chinensis), is now also common in flower-gardens. The flowers are very regular, and are supposed as possessing medicinal properties, and was used in nervous maladies. See F. N. Williams, The Pink of Central Europe (1890). — Sea-pink is a common name of Thrift (q.v.).

Pinkerton, John, an acrid little book-maker, was born at Edinburgh, 17th February 1758, and after six years' schooling at Lanark, and five years' irksome apprenticeship to a W.S., in 1780 settled in London as a man of letters, in 1802 in Paris, where he died in indigent circumstances, 10th May 1826. His twenty-four works and compilations include some mundane-architectural and historical, See Essay on Medals (1784); Letters on Literature (1786), marked chiefly by a novel system of inflection and orthography, but were the means of introducing him to Walpole and Gibbon; Ancient Scottish Poems from the Ms. Collections of Sir Richard Maitland; the Panegyric on the Duke of York; Origin and Progress of the Sycophants or Goths (1787), in which he first fell foul of the whole Celtic race; Inquiry into the History of Scotland preceding the Reign of Malcolm III. (1790); Iconography Scotiae (1790-97); History of Scotland from a National Point of View (1797); Walpoleiana (1799); Modern Geography (1802-1807); Voyages and Travels (16 vols. 1808-13); New Modern Atlas (1809-15); and Petroleum, or a Treatise on Rocks (1811). See his Literary Correspondence (3 vols. 1830).

Pink-eye is a name commonly given to an ophthalmic affection which prevails among horses, and is called by veterinarians Epizoic Cellulitis; also Rheumatic Inflammation, or sometimes Mucous Enterosis. The disease, which of late years has assumed a more virulent form, prevails during a continuance of wet weather, especially when it is also cold, and attacks in a number of animals in various parts of a town or district almost simultaneously, thus proving its atmospheric origin; but, although it thus breaks out spontaneously, there is no doubt of its being an infectious disease. The primary symptoms are loss of appetite, dulness, perhaps rigors, with fever, manifested by elevation of the temperature varying from about 104° to 107°, or, in very severe cases, even 108° F., and acceleration of the pulse. In slight cases the pulse may be 65, in very severe ones over 100 beats per minute. These symptoms are succeeded—but not always—by swelling of the eyelids and redness of the eye—hence the term pink-eye—pain in and stiffness of the lids, with tenderness, particularly around the joints. The swellings are at first limited, but soon extend upwards and downwards from the joints affected, and their occurrence gives rise to the term pink-eye. The lids become disordered; there is generally constipation at first, the faces are covered with much mucus, and in many instances there is some degree of colicky or intestinal pain. Some horses have a loud, hoarse cough, at first dry, but often becoming moist; but lung complications are not common. The disease, once established, usually becomes very feeble, though the animal presents no other bad symptom, the pain having left the limbs, the appetite returning, the swellings diminishing, and the secretions regaining the normal condition; whilst an ordinary observer is confident of a rapid recovery, the animal suddenly dies, and a post-mortem examination reveals the presence of ante-mortem clots of blood in the cavities of the heart, and perhaps in the great pulmonary blood-vessels. To the veterinarian the apparently convalescent stage is a most critical period, and he must endeavour, by roasting the heart's affection, to prevent the formation of these conglutn.

As a rule the disease runs its course favourably in from four to ten days, leaving the animal with more or less loss of condition and strength, but both sound and restored by gentle exercise. The treatment which has proved most successful is based on the conclusion that the disease runs a definite course, and that all attempts to check this are calculated to do more harm than good. It is most important that all who have the care of horses should know that it is most dangerous to work a horse when this disease prevails after
he has manifested the slightest loss of appetite; many horses turned to wood after failure of appetite have been brought back a few hours after in a dying condition. The medicines made use of are those which moderate pain if excessive, keep the contents of the stomach and bowels from undergoing putrefactive fermentation, and act as very slight aperients; and, when the heart’s action threatens the condition above described, cardiac stimulants, such as the bicarbonate of ammonia, given in a ball. Alcoholic stimulants, in virtue of their irritating properties and their effect on the nervous system, are very injurious, and should not be employed, except in an emergency, in any other disease where the so-called fibrinous state of the blood is one of the conditions.

**Pinkle.** A battle fought on 10th September 1547 near Muscelburg in Midlothian between 14,000 English under the Protector Somerset and twice that number of Scots. The latter were utterly defeated—more than 10,000, it is said, being killed on the field and in the pursuit, whilst the English loss was barely 200.

**Pink Root.** See Spigella.

**Pinn, a genus of bivalves, not far removed from mussels (Mytilidae). The shell is acutely triangular, beautifully translucent, and in some species measures two feet in length. The attaching byssus by which it is fastened to the substratum (the *byssus nubilis*), is very long and silky, and admits of being woven into fabrics. So the ancients occasionally used it, and, to gratify the curious, byssus-gloves, &c. are still made at Taranto and elsewhere. The animal is sometimes eaten. It lives from low-water mark to sixty fathoms.**

**Pinace.** See Boat.

**Pinipedia.** See Seal.

**Pinock, William (1752–1843), who is famous in the educational world as the originator of the formerly well-known catechisms which bear his name. To Samuel Maunder (q.v.), his brother-in-law, he was chiefly indebted for the production of the catechisms, which finally extended to 12 volumes, or 83 separate parts. Histories of England, Greece, and Rome ran through over a hundred editions. His son, William Henry Pinock, LL.D. (1813–85), vicar of Pinner, studied at Cambridge, and wrote on church law and church history.**

**Pinos, Isla De, an island of the West Indies, southeast of Cuba, of small extent upon the Florida Keys, 1214 sq. m. The coast has many bays. The surface is partially mountains (1600 feet), and has extensive plains; a marsh divides it east and west. It produces cattle, tobacco, lumber, turpentine, pitch, tar, marble, tortoise-shell, silver, quicksilver, iron, &c. Capital, Nueva Corona. Pop. (1899) 3199. It was discovered by Columbus in 1494, and was long a notorious port for pirates.**

**Pins.** The earliest kinds of pins were probably thorns or the small bones of fish and other animals. Among the remains found on the sites of the prehistoric lake-dwellings of Europe there are numbers of bone pins, some of a rude and others of an elegant form. The great majority of the pins in these ‘finds’ are, however, of bronze; but a few of copper and one of iron have also been discovered. It is estimated that 10,000 pins have been collected at the lake-dwellings of Seerohr in Switzerland alone. They seem to have been chiefly used as hair-pins, though no doubt they were also employed to fasten the dress, and for other purposes. The forms of these ancient pins are extremely varied, and in the numerous places where they have ornamented heads the manner and use are curious and beautiful. A few have double stems like modern hair-pins, and three found at Peschiera are exactly the same in form as the ‘safety pins’ which have come largely into use in the present year. Many of these single stemmed ones are baluster shaped—i.e. they are thicker at some places than at others. A good many both of bone and of bronze have a head formed of a loose ring in an eye. Some have bulbous heads (these occasionally being of amber) very like the safety-pins of the present time. For numerous illustrations of these ancient pins, see Munro’s *Lake-dwellings of Europe* (1890).

Among ancient articles for the toilet found in Egypt some pins with gold heads occur, and ancient Roman bronze pins and bone hair-pins, adorned with ornamentation of this kind, have been found at Pompeii. As regards modern pins, it was about 1840 that the solid-headed kind now in common use took the place of the older form of pin, which had a globular head of fine twisted wire made separately and screwed to the shank by compression from a falling block and die. These old pins had the disadvantage of frequently losing their heads. They were made by manual labour in such a way that each pin passed through the hands of fourteen different persons (see Division of Labour).

Solid-headed pins are made of an improved form of a machine which was patented in England by an American, named L. W. Wright, in 1824. But before this machine was perfected enough to do its work properly many thousands of pounds were expended upon it. Pins are made by the modern machine in this way: Pinners draw from a reel of wire a length sufficient to make a pin, which is at the same time straightened by passing between fixed studs. The pin length is seized by lateral jaws, from which a portion of the wire is left projecting. A snap head die next advances and partially shape the head; the jaws or grippers then release it, and the pin is pushed forward again about a twentieth of an inch, when the head gets another squeeze of the die. These movements of the machine are repeated once more to fasten the head, and the wire is then cut to the length of a pin. The headed blanks drop into a receptacle and arrange themselves in the line of a slot formed by two inclined and bevel-edged bars. The opening between the bars is just wide enough to let the shank of the pin fall through, so that by the action of the machine the blanks become suspended by the head in a row along the slot. When the blanks reach the lower end of the inclined bars they are caught, still hanging downwards, between two parts of the machine (one of which has a sliding movement), and passed along, rotating as they move, in front of a cylindrical cutter, with sharp grooves on its surface, so that it acts like a file, and shaped the pins. The annexed figure from the *Engineer* of June 3, 1857, shows this part of the machine, which makes pins at the rate of 160 per minute.

Ordinary pins are made of brass wire, and when these are finished by the machine they are cleaned of grease and other matters by boiling them in weak beer. The pins are next coated with tin, or ‘coloured,’ as it is called. In this process alternate layers of pins and grain-tin are placed in a copper pan, to which is added a small quantity of grain-tin and crude tartar (bitartrate of potash). When heat is applied a solution of tin is produced from which the metal is deposited on the surface of the
pins, giving them their silvery white colour. The tin surface is afterwards brightened by shaking them in a bag or barrel with bran or sawdust. Pins are 'papered' by a self-acting machine not less ingenious than the one by which they are made.

For mourning pins iron wire is used, and these are either ‘blueed’ by heating them in a muffle till the proper tint is obtained, or made black by coating them with a suitable varnish, which is afterwards hardened by stoving the pins.

The finest pins are those made of hair-like wire for insect-collectors. ‘Blanket’ pins are about 3½ inches long, and various sizes between 1½ inch and ⅙ of an inch in length are made for domestic use. Safety pins with the point resting in a loop, now so much used in the nursery and for other purposes, were, as already stated, made in prehistoric times; at least pins of exactly the same form were. The manufacture of pins is largely carried on at Birmingham, and to a lesser extent at London, Warrington, Stroud, and Dublin. They are also extensively manufactured in the United States—chiefly in Connecticut.

**Pinsk**, a town of west Russia, stands in the midst of what were formerly vast marshes (in large part drained since 1875), on a branch of the Priepet, 98 miles by rail E. of Brest-Litovsk, manufacturers leather, and has a large transit trade. Pop. 32,408, two-thirds being Jews.

**Pinzuti, Ciro**, musical composer, was born at Sinalunga, near Siena, on 9th May 1829. He studied music at Bologna (1843), and was a special pupil of Rossini. From 1848 to 1885 he lived in England as teacher of singing, chiefly at London and Newcastle. From 1856 he taught singing at the Royal Academy of Music. As a composer he wrote charming music for songs (more than 300 in all). In celebration of the union of Tuscany with Italy in 1859 he composed a Te Deum, but was not successful as a writer of larger musical compositions. He died at Florence, 10th March 1888.

**Pint**, a measure of capacity used both for liquids and dry goods, and equivalent to the eighth part of a Gallon (q.v.), or 34.6925 cubic inches. The Scotch pint, superseded as a legal measure by the imperial pint, was equivalent to 3.005 imperial pints.

**Pintado.** See Guinea Fowl.

**Pintail** (*Anas acuta*), a genus of ducks, one handsome species of which (*A. acuta*) is a winter visitor to many parts of the British coast. It is a native of all northern regions, is elongated in form, and very rapid in flight. Its flesh is much esteemed.

**Pinto, Fernão Mendes**, Portuguese adventurer, born at Montemor-o-Velho, near Coimbra, about 1510. When twenty-seven years of age he made his way out to India, and remained twenty-one years in the south and south-east of Asia, leading the life of an adventurous sea-man, fighting pirates at one time, trading at another, and again being employed on special missions to Japan or elsewhere, his fortune often fluctuating between great wealth and poverty. He returned home to Portugal in 1558, spent much time in writing an account of his adventures, adding to them embellishments and gross fictions, and died at Almada near Lisbon, probably in 1583. His travels—*Peregrinationes*—were not published until 1614, but have since then been translated into several European languages—into English by F. Cogan in 1663. See a new abridged edition of those travels, with an introduction by A. Vambéry (1891).

**Pinturicchio**, whose proper name was BERNARDINO DI BETTI, was a painter, born at Perugia, in 1454. An assistant to Perugino, he helped him with the frescoes in the Sistine Chapel at Rome, and then spent the best part of eight years (1484—91) in Rome and Naples, decorating the walls of the chapels of Santa Maria del Popolo in Rome. After executing two pieces in the cathedral at Orvieto he decorated the walls of what is now the Vatican library with a series of six frescoes; this occupied him six years (till 1498). On the walls of St Maria in Arno at Florence he illustrated the Life of St Bernardino of Siena. Other frescoes by his brush adorned two churches in Spello, the Petrenzi Palace at Siena, and the cathedral library in the same city, this last series illustrating the life of Pope Pius II. All these works are admirable examples of decorative art. Pinturicchio painted a few panel pictures of high merit, as Christ bearing the Cross, two Madonnas enthroned (at Perugia), Coronation of the Virgin (in the Vatican), and others at Siena, Florence, and Spello. He died at Siena, 11th December 1513.

See Life by Veremighioli (Perugia, 1837), two monographs by Schwarzow (Stutt. 1880 and 1882), and Milanesi's *ed. Florence, 1878* (of Vassari, vol. iii).

**Pinwell, George John** (1842—75), born in London, drew on wood, did book Illustration, and after 1865 became water-colour painter of great eminence.

**Pinzon, the discoverer of Brazil (q.v.).**

**Piorre**, the notorious rookery ('Synanthus piorre', under the leads') of the state-prisons of Venice (q.v.), in which Casanova and many other notable prisoners were confined. The heat in summer and the cold in winter are said to have been intense. Of late it has been asserted that they must have been comparatively pleasant abodes.

**Piombo,** a former principality of Italy, lies along the coast opposite the island of Elba, the greater part of which belonged to it. Its extent was 139 sq. m.; and its population, previous to its incorporation with Italy in 1860, about 25,000. Piombino, originally a lief of the empire, came in the 8th century into the possession of the Appiani, who, after ruling it for nearly 200 years, made way for the Brunswick family, who were expelled by Napoleon in 1801; but after the Congress of Vienna the principality was put under the suzerainty of Tuscany. The town of Piombino (pop. 4000), on a promontory 50 miles N. of Leghorn, has iron-rolling mills.

**Pombo.** See SEBASTIAN DEL.
that may be necessary. One is selected from each company. Instead of a rifle it carries a sawbacked sword, an axe, and two gun-spikes, other necessary tools being distributed among them.

_Cowboy Pioneers_, one from each troop, are instructed at the School of Military Engineering, Chatham, in the best method of rapidly destroying railways and telegraph lines, etc., and carry gun-cotton and the tools necessary for this purpose.

_Piotrkow_ (Ger. _Petrikau_), a town of Russian Poland, 87 miles by rail SW. of Warsaw. Cotton and wool spinning is largely prosecuted. It is one of the oldest Polish towns; here in the 15th an 16th centuries were held the elections to the Great Seals elected. Pop. 24,866. —_The government_ has an area of 4730 sq. m. and a population of 1891,1,200,197, and is the centre of a cotton and woollen industries, of brandy-distilling, and of corn-milling.

_Piozzi_, Mrs. more famous as _Mrs Thrale_, and by that name to be remembered until Dr Samuel Johnson is forgotten. Her maiden name was Hester, _Piozzi_, daughter of a wealthy family at Bodvel in Carmarthen-shire, January 27, 1741. She early gave promise of quick parts and lively disposition, and received an education that extended even to Latin as well as French, Spanish, and Italian. Early introduced into the world of literature, in 1763 she married Henry Thrale, a prosperous Southwark brewer, thirteen years her senior. He was an honest man, and made an indulgent, if somewhat indifferent, husband; but he was uncommunicative and phlegmatic in temperament. Mrs Thrale's acquaintance was wide, and through the kind offices of Mr. Smollett in January 1765, and one of the most interesting friendships in the history of letters at once began. The sage quickly conceived an extraordinary affection for his "mistress," was domesticated in her house at Streatham Place for over sixteen years, and for her sake learned to soften many of the eccentricities of his speech, dress, and behaviour. Of all his friendships this was the one most valuable to him, for _Mrs Thrale's_ warm woman's heart and constant cheerfulness henceforward brightened and gladdened all that had hitherto brought out little happiness. Thrale also had a solid esteem for Johnson, carried him with the family to Brighton, to Wales in 1774, and to France in 1775, and left him £200 as one of his four executors. He was returned to Southwark at a by-election in the end of 1765, and sat continuously until the election of 1769. Boswell first visited Streatham in October 1769, Fanny Burney in August 1778. In 1772 Thrale's affairs became embarrased, but his wife's tact and energy and the timely advances of friends enabled him to ride over the crisis. Thrale died in April 1781, and three years later the brewery was sold for £155,000. _Mrs Thrale_ had borne him twelve children, but her only son died in 1776, and she had but five daughters living at her husband's death. Dr Johnson's health was now declining, and he soon Johnson's acquaintance was broken. _Mrs Thrale_ showed no signs of suffering from the blow. She returned to Streatham for Bath in October 1782, and a few letters on the subject of the marriage passed between Johnson and herself in November 1782. The correspondence shows to more advantage than the sage. But where Johnson loved he loved deeply, and that

with a love that could bear no rival near the throne. "A friendship of twenty years," he writes, "is interwoven with the texture of life. A friend may be often found and has yet an old friend never can be found, and nature has provided that he cannot easily be lost." The marriage, for some time postponed, actually took place at Bath, 23rd July 1784, and the couple, twenty and twenty, have travelled through France, Italy, Germany, and Belgium, returning to England early in 1787. Piozzi proved an offensive husband, managed their finances with prudence, and her daughters were at length reconciled—the eldest, _Dr Johnson's_ _Queenie_, married Leyland, 1784. A second _Piozzi_ married Johnson to Streatham in 1790, but soon after built Brynella on the banks of the Clwyd. Here _Piozzi_ died in 1809, and here his widow remained till 1814, living thereafter at Bath, Clifton, and Penzance. When in 1820 Mrs _Piozzi_ broke her leg while traveling from Penzance to Clifton, and died after ten days of suffering. She was buried beside _Piozzi_ in the little church in Streatham. "Her family," as _Mrs Thrale_ was vivacious, frank, witty, thoroughly feminine, and charming, if somewhat wanting in refinement. She was pretty, if hardly beautiful—her face gave Hogarth his model in _The Lady's Last Stake_, but the best portrait is that by Sir Joshua Reynolds. _Piozzi_ lived in the same house with Mrs _Thrale_ and Horace Walpole all abused her; but she lives secure of immortality in the love of _Samuel Johnson_, and in the happiness she brought into nearly twenty years of a life radically wretched._

Mrs _Piozzi_ had a fatal facility in composition, but two of her books at least live through their subject, and indeed are only less interesting than Boswell himself: _Anecdotes of Dr Samuel Johnson during the last twenty years of his life_ (1786; reprinted in Mrs _Napier's_ _Johnsoniana_, 1881, and _Letters and _Journals_ of _Dr Johnson_ (2 vols. 1789). Her _Observations and Reflections made in a Journey through France, Italy, and Germany_ (2 vols. 1789), _British Synonymy_ (2 vols. 1794), and _Retrospection, or a Collection of the most striking Events, &c._ (2 vols. 1801) are long forgotten. Of her poems the _Three Warnings_ survives—it was first printed in the _Miscellanies of Miss Williams_ (1756), a volume containing a prose-tale of Johnson's, _The Pantomime, the heroine of which, _Floresta_ was a study of _Mrs Thrale_. Her notes to _Wraxall's_ _Historical Memoirs_ were reprinted in the 1884 edition of that work, as well as in _Hayward's Autobiography, Letters, and Literary Remains_ by _Abraham Hayward_, in 1881 (2 vols.). See the Rev. _Ed. Mangan's_ _Piozziiana_ (1833), Boswell's _Life of Johnson_, Madame _D'Arblay's_ Diary, _Mr Hayward's_ _Introduction_, and _J. B. Sibly's_ _Mrs Thrale_ (1881).

_Pip_ is the name by which various diseases in both fowls and poults were once known, but since the affections of birds have been studied, and more accurate knowledge arrived at, this term is no longer in use. See _Roup_.

_Pippa_, a genus of amphibiens, of which the best known is the Surinam toad. See _AMPHIBIA_.

_Pipal_, a species of fig. See _PREPUL_.

_Pipe_, a measure of quantity commonly employed in Portugal, Spain, France, England, and in some other countries, used almost exclusively for wine and oil. In English it is also called a butt, and is divided into two hogsheads. But the capacity varies with the locality as well as with the description of wine the cask contains: a pipe of port is 137
Pipeclay.

Pipeclay, a fine white plastic clay, very like kaolin, but containing a larger percentage of silica. For the manufacture of tobacco-pipes the most desirable clay contains only small traces of limonite and alkaline earths. Clays of this nature are met with in Cornwall, Devon, and Dorset, but the purer varieties of clay used for pottery-making are also employed in the manufacture. Such clays, however, have siliceous materials added to them artificially. Pipeclay is used by soldiers for whitening belts, &c.

Pipe-fish, a family of remarkable fishes in the same (Lophobranch) order as the Sea-horses. The body is elongated like a thin pipe; the jaws are prolonged in a tubular toothless snout; the muscular development is slight; the skin is covered with an armature of hard plates; the gills are in the form of tafts, and the branchial aperture is very small. The eggs are carried about and hatched by the male, usually within a capacious pouch formed from two folds of skin on the ventral surface of the tail-region. One of the commonest British species is the Great Pipe-fish (Syngnathus acus), which is sometimes found in deep water, and sometimes at low tide among the seaweed in rock-pools. The specimens commonly seen are from 1 foot to 18 inches in length. It may be seen slowly moving about, with curious contortions, poking its long snout into every crevice in search of food, and sometimes assuming a vertical position with the head downwards, boring into or stirring the sand.

Pipe-fish (Syngnathus acus).

One of the commonest American pipe-fish is Siphonostomus pecki, which lives among the eelgrass of the coast.

The name Pipe-fish is sometimes given also to the fishes forming the family Fistularidae, or Plume-mouths, of which one of the most remarkable is the Tobacco-pipe-fish (Fistularia tubococera). But these are large marine sticklebacks, and have only a superficial resemblance to the true pipe-fish.

Piperaceae, a natural order of exogenous plants, natives almost exclusively of the hottest parts of the globe, particularly of Asia and America. About 600 species are known, to most of which the name Pepper (q.v.) is sometimes given, although some are also known by other names, particularly those of which the fruit is not used as a spice, but of which some part is employed for some other purpose, as Betel, Cubebos, Matico, and Ava.

Piperine, an Alkaloid (q.v.) found in pepper.

Pipercorns. See Records.

Pipes are made of various materials and for various purposes. Thus, we have draining-pipes for agricultural and sanitary purposes, made of earthenware, wood, and metal (see DRAINAGE, SEWAGE), pipes of various kinds of metals for a great variety of purposes, and Tobacco-pipes (q.v.) of various materials. Earthenware pipes are now made of almost every size, from an inch or two in diameter up to the enormous size of 54 inches. They are usually made of fire-clay, and are glazed like common Pottery (q.v.). Caoutchouc vulcanised and gutta-percha are also extensively used for making pipes. Lenthal pipes are used chiefly for the conveyance of water temporarily, as in the case of fire-engines (see FIRE). Metal pipes are made of iron, lead, tin, or an alloy of tin and lead, copper, brass, &c. Iron pipes, as for water and gas, are usually cast, and the manufacture is one of enormous extent. See Water-supply.

Pipes of ductile metal, such as brass, copper, and tin, are made by first casting an ingot into the shape shown in fig. 1, with a hole through its length of the same diameter as the bore of the pipe is intended to have. Into this is placed an iron rod, called the mandrel (a, fig. 2), which exactly fits, and which projects slightly at the tapered end (b, fig. 2). It is then brought to the drawing-table, and here the small end with its projecting mandrel is put into a funnel-shaped hole, drilled through a steel post (a, fig. 3), so as to allow the point to be gripped on the other side by a pair of pincers, at the end of a strong chain; the machine-power is then applied to the other end of the chain, and the soft metal and its mandrel are drawn through, the former being extended equally over the surface of the latter, which is then removed, and the length of pipe is complete. Some metals require repeated drawing through holes, getting gradually smaller, and have to be softened or annealed at intervals, as the metal hardens under repeated drawing. In this way brass, copper, tin, and pewter pipes are made; and a patent has also been taken out for making steel pipes; but lead pipes are made of great lengths by squeezing the soft metal through a hole in a steel plate in which there is a fixed core or mandrel projecting, which forms and regulates the size of the bore of the pipe. Pipes are also made from copper, brass, and malleable iron by rolling out narrow strips of metal, and then passing them successively through rollers, which are deeply grooved, and which turn up the edges (fig. 4). A mandrel is then laid in it, as in fig. 5, and it is next passed through double-grooved rollers, which turn the edges in, and thus form a complete tube round the mandrel. The edges, however, require hard soldering — i.e., soldering with a fusible brass alloy, or welding, if of iron. All boiler-tubes used to be made in this way; but the method of drawing has lately been so much improved that copper and brass pipes, or tubes, as they are frequently called, are now drawn of considerable thickness and diameter.
Piracy

Pipì, the name given to the ripe pods of *Cesalpinia-pupai* (see *Cesalpinia*), which are used in tanning, and are not unfrequently imported along with Dividivi (q.v.).

Piping Crow, a name somewhat loosely applied in Australia to any bird of the genus Gymnorhina or Barita (q.v.). Another modification of the name is Piping Crow Shrike or Piping Roller; the bird is also called Carrick.

Pipit (Anthus), a genus of small birds forming with the wagtails the family Motacillidae. The pipits have a strong resemblance to the larks in external appearance, and even in many of their habits, such as singing while on the wing; but they moult twice a year, while larks moult only once. With the same general habit except in colour, and like them they are chiefly terrestrial in habit, running along the ground, working in and out among grass or heather in search of the insects, worms and slugs which form their food. The Meadow-pipt (Anthus pratensis), also known as the Tilthark or Moss-chesper, is the species most abundant in Britain. It breeds early in spring, nesting in a hollow on the ground or under a bank, and rears two broods in a season. The Tree-pipt (A. trivialis), though only a summer visitor, is common in many districts, and breeds freely in the south and west of Scotland. The Rock-pipt (A. obscurus) frequents rocky shores and feeds on molluscs and small crustaceans.

Pippi. See Giulio Romano.

Pippin. See Petin.

Pippin, a name given to many varieties of apple, among which are some of the finest in cultivation, as the Golden Pippin, Ribston Pippin, &c.

Piqua, a city of Ohio, on the Miami River (here crossed by two bridges), 28 miles by rail N. of Dayton. It has foundries, oil-refineries, and manufactories of flour, furniture, mattresses, &c. (1900) 12,172.

Pique, a game at cards for two players, played with thirty-two cards, the sixes, fives, fours, threes, and twos being rejected. The game was formerly played a hundred up, a partie being the best of five games; but about 1800 the rubicon game superseded piqué au cent. At the rubicon game six hands are played, each player dealing alternately. The one whose aggregate score is the higher wins the partie. He deducts the loser's score, and adds a hundred to the difference. If the loser fails to score a hundred in the six hands, he is rubiconed, as the score is added instead of being deducted. For a description of the mode of play, handbooks should be consulted.

The earliest known mention of piqué is by Rabélais in the Gameanist list of games (1530-45). Hence it has been concluded that piqué is of French origin. But it is more probable that a similar game, called rongh, was played in Italy at an earlier date, and that this game, with modifications, travelled from Italy to Spain, where it was re-named *piquet* and to France, where it was re-named *piquet*. Piqué seldom, if ever, occurs in English books of the Shakespearian period, but *cent* (cents) frequently does. From this it may be concluded that piqué, under the name of cent, was played before the end of the 16th century, and in the middle of the 17th century, when the word *cent* went out of use, and was replaced by the word *piquet*. It may be noticed in this connection that from the time of the marriage of Mary to Philip of Spain (1554) the English equivalent of the Spanish name of the game was in use, and the marriage temporarily with the marriage of Charles I to the daughter of Henry IV, of France (1625) the French name *piquet* was substituted.

The etymology of piqué has been much speculated on; no satisfactory settlement has been arrived at. In 1661 was published *The Regall and Delightfull Game of Piquet*, translated from the earliest known French book on the subject. This was followed by several others, more or less resembling it, *Wit's Interpreter* (1671), *Cotton's Compleat Gamester* (1676), and *Seymour's Court Gamester* (1719), all containing piqué. The next original work was *Hoyle's Short Treatise on the Game of Piquet* (1744). This included the laws which were the authority until 1873, when the Portland Club issued a code. The general adoption of the rubicon game, shortly after 1800, necessitated a fresh revision; and in 1881 the Portland and Turf Clubs agreed to the code of laws which now governs the game. These laws were published in 1882, together with a treatise on the game, by Cavendish.

Piracy (Lat. pirata; Gr. πιρατας, 'an adventurer,' 'a pirate'); robbery on the high sea, was apparently very much mixed up with early maritime adventure, the sea-rover being frequently pirate as much as trader; thus, the Phoenicians often combined piracy with more legitimate sea-faring enterprises. The Huns, who in the 5th century, had accountèd a reputable or even dignified calling; and the Greeks, especially the Phocæans, long displayed a natural genius for piracy. This aptitude was cherished by the constant warfare between small states, it being difficult sometimes to decide what was piracy and what was private war. Cicero speaks of a time when the Mediterranean was long the headquarters of Mediterranean piracy, until in 67 B.C. Pompey made his memorable expedition against the pirates with great naval and military forces. From the 8th to the 11th century the Norse vikings were the terror of the western coasts and waters (see Norhtemen). The Hanseatic League (q.v.) had its origin in the desire for mutual defence against Baltic and other pirates. At a later date the Moslem savages scourged the Mediterranean, commingling naval war on the large scale with peddling, thievry, and the abduction of slaves: Algiers was a piratical stronghold till well into the 19th century (see corsairs); and in the 17th century the English Channel swarmed with Algerine pirates, who snapped up in one prize £300 worth of linen belonging to the Lord Deputy of Ireland, and being the king's representative, for weeks in an English port while he waited for a ship-of-war to convey him across the Irish Sea. In 1635 they actually entered Cork harbour, and carried off a boat with eight fishermen, ten cows, and three sheep. The Bucaneers (q.v.) preyed mainly on the Spanish commerce with the Spanish American colonies. Lundy Island (q.v.) was long a nest of pirates, English and other. Captain Kidd (q.v.) is in the popular mind the chief representative of the picturesque type of pirates, whose career of reckless bloodshed and rapine under their 'Jolly Roger' or
PIREUS

black flag, alternating with luxurious debauchery, has come to be surrounded with a halo of romance, reflected in E. A. Poe’s *Gold Bug* and R. L. Stevenson’s *Dr Jekyll and Mr Hyde*. The name *Pirate* was John Gow, who in January 1725 boldly anchored in Orcadian waters, and entered into friendly relations with the islanders, till, recognised as an atrocious villain, he was with his crew captured and carried to London to be tried. He and eleven of his companions were confined in a month or two after, and the pirate captain and nine of his men were executed together. So late as 1864 five men were hanged in London for murder and piracy. National prejudices tend to obscure the distinction between Privateering (q. v.) and piracy: Paul Jones was a pirate in England, and the commanders of the Confederate ships *Alabama*, *Seminole*, and *Florida*, which preyed on northern commerce, were in northern eyes practically pirates. Of late the pirates tried by admiralty courts are rather naval mountebanks than pirates in the old sense. The African slave-trade was not considered piracy by the law of nations; but the municipal laws of the United Kingdom and of the United States by statute declared it to be so; and in or after 1841 it was declared to be so by Austria, Prussia, and Russia. The home of professional piracy, happily now in abeyance, is the Malacca Archipelago and the China Seas; Sea-Dyaks and Malays disputing with Chinamen the palm of hardihood as sea-robbers.

Piracy is recognised as an offence against the law of nations. It is a crime not against any particular country, but against all mankind, and may be punished in the competent tribunal of any country where the offender may be found, or into which he may be carried, although committed on board a foreign vessel on the high seas. It is of the essence of piracy that the pirate state has not obtained permission from a sovereign state, or from one belligerent state at war with another. Pirates being the common enemies of all mankind, and all nations having an equal interest in their apprehension and punishment, they may be lawfully captured on the high seas by the armed vessels of any particular state, and brought within its territorial jurisdiction for trial in its tribunals; but it is not permitted to put pirates to death without trial save in battle.

The infringement of the Copyright Acts is often spoken of as literary piracy; and the word is now extended to cover the case in which the publishers of one nation issue unauthorised reprints by authors of another nation—especially the case of American reprints of English works (see BOOK-TRADE, Vol. II. p. 316). Thus, several pirated reprints of the first edition of this Encyclopaedia were issued and were being sold in 1890, in which obsolete facts and statistics twenty years old were reproduced with marvellous fidelity.

PIREUS (Gr. Peiraius), called also PORT UCARAC, the harbour of both ancient and modern Athens (q. v.). Planned by Themistocles and laid out by Hippodamus of Miletus, the Piraeus is built in the glorious days of Pericles; this ruler and Cimon before him built the three ‘long walls’ that connected Athens with its port (5 miles to the south-west), and so ensured a free and safe passage from one to the other at all times. It was both a war harbour and a commercial port, many foreign vessels lived with it. In ancient (built 347-325 B.C.) and fortiﬁcations were destroyed by Sulla in 86 B.C., and from that time the town sank into decay. The modern Piraeus, which has grown up since 1834, is a regularly laid-out but mean-looking town, which contains grain-mills, arsenals, docks, and manufactures of cottons, ﬂour, paper, iron, nails, ears, furniture, &c., and is growing rapidly. A railway (1869), 5 miles long, connects it with Athens. The foreign trade (£4,000,000 annually) is half that of all Greece. The imports are mainly coal and railway plant, &c., from Britain; petroleum from the United States, and sheep and cattle from Russia; and the exports, tobacco, valonia, hides, bones, horns, cheese, wool, &c. A total of 6000 vessels of 21 million tons enter annually, one-half the tonnage being in Greek bottoms. Pop. (1871) 11,009; (1879) 21,655; (1890) 38,500.

Pirano, a seaport of Austria, on a promontory on the south side of the Gulf of Trieste and 12 miles SW. of the town of Trieste. It has two harbours, one an old castle, and manufactures of soap, glass, &c., with neighbouring salt-works. Pop. 9419.

PIRACALIS, See DÜREK.

Piramasen, a town of the Bavarian Palatinate, and formerly the chief town of the county of Hanau-Lichtenberg, 34 miles by rail W. of Landau.

The chief manufactures are shoes and musical instruments. Close by the Prussians under the Duke of Brunswick defeated the French commanded by Moreau on 14th September 1793. Pop. (1855) 14,938; (1895) 24,548.

Pirna, a town of Saxony, stands on the left bank of the Elbe, 11 miles by rail S. of Dresden. Here are a fine 16th-century church; a castle (1573) of the Duke of Saxony; a lunate archery-tower; manufactures of glass, chemicals, tobacco, stoves, &c. Eight thousand men are employed in the sandstone-quarries. Pop. 15,670.

PIROGUE, See PERAGUA.

Piroi, a town of Servia, on the Nisachova, 30 miles E.S.E. of Nisch. It was occupied by Servian troops in 1877, and taken by the Bulgarians in 1885. Pop. 8000.

Pisa, one of the oldest cities of Italy, the rival of Venice and Genoa, which still has its walls standing and a citadel, is situated on the Arno, by rail 49 miles W. of Florence and 13 NE. of Leghorn. It was formerly a great port, though six miles from the sea, but owing to the silt ing up of the river is now of commercial importance. Shrimp and salt-fish are exported, and there are manufactures of glass, chemicals, tobacco, stoves, &c. Eight thousand men are employed in the sandstone-quarries. Pop. 15,670.

PISTOIA, called also PORTO GRAQ, the harbour of both ancient and modern Athens (q. v.). Planned by Themistocles and laid out by Hippodamus of Miletus, the Piraeus is built in the glorious days of Pericles; this ruler and Cimon before him built the three ‘long walls’ that connected Athens with its port (5 miles to the south-west), and so ensured a free and safe passage from one to the other at all times. It was both a war harbour and a commercial port, many foreign vessels lived with it. In ancient (built 347-325 B.C.) and fortiﬁcations were destroyed by Sulla in 86 B.C., and from that time the town sank into decay. supports a dome, crowned with a cupola. The interior, noted for its wonderful echo, contains the grand and elaborate pulpit of Niccola Pisano (1260) and a large marble font. The beginning of the Campo Santo, or ancient national cemetery, was several loads of earth brought from Jerusalem towards 1200. In 1278-83 the ground was surrounded by cloisters by Giovanni Pisano, the walls of which were adorned with fresco-paintings by Orcagna, Benozzo Gozzoli, and others. The city contains

the pattern upon which the sea-laws of nearly all peoples navigating the Mediterranean were modelled. During the same century the Pisans repulsed the Saracens (1114). It was from 1202, attacked them in Africa, in 1090, and routed them utterly off Palermo in 1062. Early in the next century, in 1114-16, they wrested the Balearic Isles from the same enemies. In the second crusade too they played a prominent part, and helped the Turks against the Normans, taking Amalfi in 1135 and again in 1137. But already in the 11th century the rivalry between Pisa and Genoa had broken out. Florence too, a Guelph city, grew into an enemy of the Ghibelline Pisa. Wars many and often were waged between Pisa on the one side and a coalition of cities, headed by Florence and Genoa, on the other, with varying fortune, until in 1284 the Pisan fleet was crushed at Meloria. After this Pisa was compelled to give up Corsica, part of Sardinia, and 160,000 gold pieces to Genoa. At the same time Ugolino (q.v.) della Gherardesca made himself master of the town. Various individual rulers or tyrants followed, until the Pisans finally threw themselves (1399) under the protection of Galeazzo Visconti of Milan. The son of the latter sold the Pisan territory to the next powerful enemy, from whose tyrranical rule they were for a time relieved by Charles VIII. of France, who, in 1494, accepted the protectorate of the city. When the French left Italy the old struggle was renewed; and, after a desperate resistance, the Pisans, in 1560, were compelled by hunger and terror to yield to the Florentine army.

The most influential families, as formerly in 1406, emigrated. From this time Pisa steadily declined, until in the middle of the 18th century it had less than 8000 inhabitants. Its history henceforth coincides with that of Tuscany (q.v.). When the rest of Tuscany it became part of the kingdom of Italy in 1860.

The Council of Pisa met in Pisa on March 25, 1469, and of which the twenty-third and last session was held on 7th August following. Its aim was to end the schism which had divided the Western Church for thirty years, and with this view the leading cardinals, finding that neither of the rival popes, Gregory XII. and Benedict XIII., would keep their promises to abdicate, set aside the claims of both, and themselves convoked a general council which was attended by 24 cardinals, 4 patriarchs, 80 bishops, 102 prelates of bishops, 87 abbots, 200 delegates of abbots, besides many generals of orders, doctors, deputies of universities, and ambassadors. After the rival popes failed to appear in obedience to its summons, the council formally tried the claims of both in turn, and deposed them as schismatics and heretics. The cardinals then formed themselves into conclave and elected Cardinal Philargius, who assumed the name of Alexander V. But the council, instead of getting rid of the enmity and union of the continent in third, and the faithful continued to be distracted in their allegiance for eight years longer, down to the time of the Council of Constance. Bellarmine considers the Council of Pisa as 'neither clearly approved nor clearly rejected'; Hefele says 'neither ecclesiastical nor theological nor theological, nor the theologians have ever numbered it among the ecumenical councils.' See Hefele's Concilien-

Leaning Tower and Cathedral, Pisa.

numeros other churches, some of great age, dating from the 13th century and even earlier; also many fine palaces, private and official residences, including that of the archbishop. The university (1338) has a natural history museum, a botanical garden, a library (1742) of 120,000 volumes, and sixty lecturers and 600 students. The town possesses an academy of fine arts and archives. Amongst distinguished natives may be named the popes Eugenius III. and Nicholas V., the Visconti, Peter the Deacon, Leonardo the mathematician, Giovanni (but not Niccola) Pisano, and Galilei. The industrial activity is now confined to cottons, silks, ribbons, and the working of coral and alabaster. Dromedaries are bred at a royal farm in the neighbourhood. Pop. of commune (1891) 52,057; (1896) 64,700. The province has an area of 1180 sq. m. and (1896) a pop. of 311,742.

History.—Ancient Pisa, originally an Etruscan city, became subject to Rome in the 2d century B.C.; but, on the decline of the western empire, it was compelled to submit in turn to the nations who successively overran Northern Italy. Early in the 11th century Pisa had developed into a powerful republic, possessing a formidable fleet and extensive territories along the Tyrrhenian Sea; it yielded little more than nominal homage to its suzerain lords, the emperors of Germany. Throughout the 11th century Pisa was at the height of its prosperity; to this period belong most of the splendid monuments of art that still adorn the city. It had extensive commercial relations with the East; its 'customs of the sea' (1075) were
Piscataqua

His earliest work is supposed to be the 'Deposition' over one of the doors of the cathedral at Lucca, dated 1237. His reputation is supported by three important works, which are still admired for their excellence—the pulpit of the baptistery at Pisa (1260), the 'Area' or shrine of St Dominic for the village of Siena at (1267), and the pulpit of the cathedral at Siena (1268). He died at Pisa in 1278, and was buried in the Campo-Santo. He was also a great architect and a skilfulengineer. His influence on art was wide, reviving the love of beauty and giving new birth to the painting arts. Arnolfo and Lupo executed numerous works at Rome, Siena, and other cities. His son and heir in reputation, Giovanni Pisano (1250-1330), was not his equal either as sculptor or as architect. Niccolò's pupil Andrea Ponsello, generally called Andrea Pisano (1270-1349), was first a goldsmith, but became famous as a worker in natural bronze and a sculptor in marble. He settled in Florence, and his best work there (one of the baptistery doors and many sculptures on the Campanile) shows strong traces of Giotto's influence. Vitore Pisano, or Pisanello (1390-1455), was born from the younger generation, and the Croce and Cavalcaselle, Painting in Italy (1864); Symonds's Renaissance in Italy (1886); Leader Scott, Early Italian Sculptors (1882).

Piscataqua, a river which constitutes part of the boundary between Maine and New Hampshire, and forms at its mouth the excellent harbour of Portsmouth. See New Hampshire.

Pisciculture. Fish-culture is the art of increasing the supply of food-fishes—first, by breeding and rearing them artificially; secondly, by preserving the gravid fish and the natural spawning and nursery grounds through legislation; thirdly, by creating new breeding grounds through the removal of obstructions or the placing of fences, stakes, tiles, &c. for the collection of ova or of spat; lastly, by increasing the amount of natural food in any practicable manner. In recent years the artificial culture of sea-fish has been attempted on a large scale in several countries. In the United States and in Norway fully-equipped hatcheries for sea-fish and shellfish have been in operation for a number of years. In 1868 the Newfoundland government erected a marine hatchery at Dildo, Trinity Bay; and a similar establishment was completed in 1891 by the Canadian government near Placent, on the Northumberland Strait, Nova Scotia. In 1890 the Newfoundland hatchery turned out fifty thousand fish for seeding and sold to the value of hundreds of millions of young lobsters. In Britain the hatching of sea-fish has not yet been undertaken on a large scale; but very excellent experimental work has been done at Plymouth by Mr J. T. Cunningham, who succeeded in artificially fertilizing the eggs of herring and sole in the early part of 1890; at St Andrews by Professor M'Intosh; and by the Fishery Board for Scotland at Dunbar. Under the second head the Fishery Board for Scotland entered in 1883 on a scale experiment to ascertain what legislation, if any, was required to protect the inshore waters, either as spawning, nursery, or food-producing grounds, and several bylaws have been passed protecting the greater portion of the Scottish inshore waters. These provisions were extended by the Herring-fishery ('Scotland') Amendment Act, 1889.

Ponds for fresh-water fishes have been common from a very remote antiquity. It appears from Isaiah, xix. 10, that they were used in ancient Egypt. In the times of Roman luxury almost every wealthy citizen had fish-ponds. The Chinese have long bestowed more attention on pisciculture than any other nation, and with them it is truly a branch of economy, keeping up the supply of food, fish being used as much as meat by rich and poor at every meal. In China a large proportion of fish for the markets of the interior are reared in ponds. Some of these are generally placed in front of the villages, and many at large reservoirs. At the time of harvest they are caught and sent to market. Carp, perch, tench, and bream are some of the kinds kept in ponds. In some countries of modern Europe this branch of pisciculture is also prosecuted to a very considerable extent, particularly in Germany and Sweden, and of late years in France, in order to increase the supply of fish for the market. In Britain it has only recently been systematically prosecuted. The country-seats of the nobility and gentry have, indeed, been generally provided with fish-ponds, but in most instances rather as ornamental waters than for use. In the northern provinces of Britain, the trout, perch, and pike are almost the only fish kept in ponds; in England they are often stocked with carp and tench, and are turned to much better account than in Scotland. In Germany ponds are carelessly stocked, and are used merely for sport and remunerative. There can be no doubt that in Britain also many a piece of land at present very worthless might easily be converted into a pond, and made to yield large quantities of excellent fish.

The greatest improvement in pisciculture, and a most important branch of it, to which the term is often restricted, is the breeding of fish in artificial breeding-places, from which not only ponds but rivers may be stocked; or the art of fecundating and hatching fish-eggs, and feeding and protecting the young animals till they are of an age to secure their own food and protect themselves from their numerous enemies.

In the middle ages, and especially in the 14th century, fish-ponds were common in the domains of princes and nobles and religious communities; but those were mere ornamental ponds, and the first attempt at artificial fertilisation of fish eggs appears to have been made at the beginning of the 15th century, by Dom Pinchon, a French monk; but his experiments attracted no attention. Between 1725 and 1735 Stephan Ludwig Jacobi of Hohenrettau in Bavaria, who was professor of chemistry, but who was entirely independent of the official; but commercial pisciculture owes its origin to the French, the art having been first practised by Réuy, a poor fisherman who worked the streams of La Bresse in the Vosges. It was the great waste of eggs incidental to the natural system of fish-breeding that led Réuy about 1830 in conjunction with a partner, Géhin, to try to reduce the fish-streams of his native district. His plan, being successful, attracted the notice of many of the French savants, and led to preference for Réuy; the nobility was keen to adopt the plan, and the government. At Hünningen in Alsace, on the Rhine, a gigantic fish-nursery and egg-depot was erected in 1802, chiefly through the energy of M. Coste. Since the cession of Alsace to Germany the operations of the establishment at Hünningen have been conducted on a still larger scale by a German association.

Réuy and Géhin's plan of rearing trout artificially is this: At the time the female is about to spawn she is caught and gently pressed on the abdomen by the hand, when the ova or eggs spurt forth into a vessel containing water. In the same way the milt is taken from the male. The eggs
are well mixed with the milt, and the water changed once or twice. The fecundation being completed, the next thing is to place the eggs for security into a covered vessel. Its early form was that of a flat, round box about eight inches in diameter, with a hinged lid. This was made of zinc, perforated with small holes, and had a layer of fine gravel on the bottom. A considerable number of fecundated eggs were enclosed in the box, which was then placed in the bed of a current of pure water and covered with pebbles, care being taken that the water passed freely through, as it is necessary for the eggs to be slightly agitated. The hatching takes place in from two to four months, the time depending on the nature of the water and other circumstances. For a description of the early changes which the fish undergoes, see Salmon.

After the little fish are fully formed they are kept in the box from eight to fifteen days, and then set at liberty. The later plans for artificially propagating trout or salmon differ principally in mixing the milt and milt in an absolutely dry utensil and in the details of the hatching-boxes, in the use of houses, and in many of the young fry being kept in ponds till they are a year or more old.

The most sustained effort in British pisciculture has been in connection with the salmon fisheries of the river Tay. At Stornonvole, near Perth, since 1833, a series of open-air hatching-boxes, covered with gravel and capable of receiving 50,000 eggs, have been in use; but for years nothing like this number have been hatched, and probably not 20,000 young fish annually have for some time past been turned out of the ponds there. The Tay District Fishery Board in 1883 erected a new hatchery a few miles away at Dupplin on the Earn. It was put up to try the system of glass grill hatching-boxes, designed prior to 1860 by M. Coate of Paris, and presently to be described as in use at Howietoun. On this plan it was estimated to hatch 300,000 ova. But in the autumn of 1883 the Board decided to adopt only partially the grill hatching, and to try along with it the simpler Canadian system of shallow trays of perforated tin-plate, and coated with Japan varnish; in which the eggs, instead of being in separate rows, are packed very closely together, river-water being used. In 1889 it was stated to be capable of hatching four or five hundred thousand fish.

The most extensive fish-rearing establishment in Great Britain is the one belonging to Sir James Maitland, situated at Howietoun, near Stirling. It consists of hatching-houses and, at a distance from them of half a mile, an extensive series of ponds. The principal hatchery is 86 feet long by 40 feet wide, each of its two stories being 10 feet high. Its walls, built of brick and concrete, are nearly 2 feet thick; and the roof is covered with a layer of concrete 3 inches thick, over which there is a thin cover of asphalt. The entire outer shell is thus a bad conductor of heat, so that it is not difficult to keep the water inside from falling below 44° F. Fig. 2 gives a sectional view of the hatchery. It will be seen that each floor has a considerable slope, which admits of the hatching or grill boxes (Fig. 2) being placed in descending series. These are 154 in number, the ordinary size of them being 6 feet 9 inches long, by 1 foot 7 inches broad. In the bottom of each box four wooden frames are neatly fitted, each of which has rather more than 100 glass tubes, about \( \frac{1}{4} \) inch in diameter, placed transversely. Fig. 1 shows a longitudinal section of one of these hatching-boxes, in which the dotted line indicates the position of the glass tubes. Upon these glass grills the fish-eggs lie in parallel rows, looking like small pink beads. Six cisterns or tanks \( \{b, b, b\} \), each 20 feet long and five feet broad, are fitted up in the lower portion of the ground-floor to receive the young fry after they begin to take food. At Howietoun both hatching-boxes and rearing-tanks are constructed of wood charred on the internal surfaces, and painted on the outside, their ends being formed of perforated zinc, which is closed with flannel when any depth of water is required in the tanks. At other hatcheries, however, the tanks and boxes are formed of slate, and sometimes of earthenware, but in such cases they are of smaller size. Often, too, the eggs are placed on perforated zinc or porous earthenware instead of glass grills. While the eggs are being hatched only spring water is used. It is brought underground to the two cisterns \( \{c, c\} \), and from these it is conveyed by lead pipes \( \{p, p, p, p\} \) to each series of hatching-boxes, over the grills of which it flows in a constant but not rapid stream. Each of the hatching-boxes contains about 15,000 eggs, but in the earlier part of the hatching-season (December) eggs are also placed in the 20-feet tanks, so that about four millions of
fish-eggs can be brought to maturity in one season. In 1890-91, 2,310,000 eggs were incubated, 81,500 yearling trout sold and 40,000 yearling trout retained, to grow into two-year-olds, and 19,000 two-year-old trout sold and 6,000 retained.

The ponds at Howtown are extensive and ingrown with reeds for reasons of convenience. Water is supplied to them by a barn issuing from Loch Conter, a lake of considerable size, and largely fed by springs. They are divided into a larger and a smaller group. The former consists of ten ponds, of which the largest measures 290 feet in length by 90 feet in breadth, and 12 feet deep. Next to this is a sub-group of three ponds lying parallel to each other, each 270 feet by 45 feet, and 10 feet deep. These also contain Lochleven trout of different ages, and about 5000 in number in each pond. The remaining twenty-five ponds are each about 100 feet long, and contain respectively American brook trout (Salmo fontinalis), yellow trout (Salmo fario), and more Lochleven trout under three years of age. Their various levels are so arranged that by means of open tracts and dividing-boxes the water is slowly but constantly filtered through the water and best in the series, and sluices are provided so that any single one can be emptied when required. Each pond is also provided with a cleansing pipe.

At Howtown the young fry are fed chiefly on grated eggs and beefsteaks made up into strings like macaroni. The strings and worms are mixed on minced horse-flesh, and older trout on shellfish. But some pisciculturists strongly recommend that additional kinds of food, such as boiled liver, chopped worms, fish-roe, and biscuit-dust, should be given in turns to fry. A large proportion of trout-diet—many, as some experimenters and persons think, of starvation—during their first year, even when kept in ponds regularly supplied with food. The strong repel and devour the weak at feeding-time, but the mortality, in so far as it may be caused by food at all, is probably more due to the kind used, or to the form in which it is given. In the case of rearing-ponds situated near the sea, mussels and shrimps are much used for feeding purposes. At Guildford, Surrey, the trout are allowed to find their own food, but with this system the ponds must be large in proportion to the number of fish contained in them, as well as favourably situated with respect to a sufficiency of natural food. Near St. Viten, Lower Austria, this plan is adopted. There are a number of small ponds or ditches with stagnant water and aquatic plants, which are used as nurseries to propagate the larvae of insects, small crustaceans, and other low forms of animal life on which trout naturally feed. From time to time part of the water swarming with these creatures is admitted to adjoining ponds with pure water in which the fish live. It probably depends on the locality of the particular method of feeding succeeds best in a commercial sense.

In Great Britain it is as yet only members of the Salmonidae family which have been artificially reared on a commercial scale. But quite recently some attention has been given to the cultivation of white trout (Coregonus albus), in which 21,800,000 fry were raised by five members of the Perdie family, besides smaller numbers of other species, making a total of 67,000,000. The common or Atlantic salmon has been introduced into Tasmania, and seems now to be thoroughly acclimatised, numbers of adult fish, besides shoals of the young, occurring in the rivers. One or more species of British trout have also become established in Tasmanian as well as in Australia and New Zealand rivers. At Otago, there is a trout-hatchery. In Victoria the Californian salmon has been found to succeed better than the American white, as it is more adapted for the climate, and the water is not so great. They have all, more or less, a comparatively insipid taste, but this could no doubt be improved by proper attention to their food. Pike being great cannibals, there is more difficulty in stockling ponds with them, even when there is not much difference in their size, than with most other fish. Perch—which have an extraordinary power of increase—spawn readily in confinement, but it is said that the fry are not very easily reared. In America persevering efforts are being made to acclimatisé the mirror carp, which is a favourite fish for the table in Germany. See Pike, and Carp.

Pisciculture is practised in America on a very large scale. The United States Fish Commission have several stations for hatchling eggs of the Salmoideæ, the largest being on the M'Leod River, California, established for the ovum of the California salmon (Salmo clarki). The California commissioner, Professor Spencer Baird, gives the total production: of eggs at this station for the season of 1879 as about 9,500,000; but the number for 1878 was 14,000,000. In 1879, 2,900,000 were hatched at the station to keep up the stock in the Sacramento River, 4,150,000 were taken to the eastern states, and the remainder were sent to Canada, France, Germany, and Holland. The Californian salmon can adapt itself better than the common species to comparatively warm water, so that it will thrive in some rivers where the latter will not; but whether it will prove equally well adapted to the colder waters of Europe is still a matter of uncertainty. This station is now chiefly used for hatching the rainbow trout (Salmo irideus), 28,700 fry being planted in the M'Leod River in 1885. There is another hatching-station at Buckport, Maine, for the Atlantic salmon (Salmo salar), and one for the Grand Lake Stream, Maine, for breeding the Schoodic or landlocked salmon, which is a variety of the Salmo salar. In the United States there are several hatcheries for the propagation of shad, the aggregate yield of which in 1884 was 9,600,000. The hatchery at the station at Caledonia, in that state, has distributed 18,000,000 trout, salmon-trout, carp, pike, and muscalongue in one year. Hatching-stations for the cod and other sea-fish are also being tried. For oyster-culture, see OYSTER.
PISCINA

Francis (1865), Fry (New York, 1896), Goode (in the Trans. Amer. Fish-culture Assoc., New York, 1881), Gorlick (24 ed., Cleveland, Ohio, 1893), Green (on trout, Rochester, N.Y., 1870), Gwy (on stocking, 1884), Jacobson (from a Report of the U.S. Commission, 1880), Sir James Maclead (a history of Howlett, 1887), Giffen (on salmon at the Antipodes, Philadelphia, 1885; Lond. 1889), Roosevelt (Rochester, N.Y., 1879), Slack (on trout, New York, 1872), Stone (on trout, Charleston, 1877), Wilmot (on Canadian fish-culture, Ontario, 1882), Wilson (on salmon at the Antipodes, 1879). Also French works by Coste (1850 and 1858), Géhin and Rémy (1851), Lamiral (1851), Lamé (1860), Millet (1870), Quatrefages (1854), Bavaret Wotté (1874 and 1878), Rémy (1854 and 1856), De Bon (1880); Gobin, *La Pisciculture en Eaux Douces* (1889), *La Pisciculture en Eaux Saltées* (1891); and German works by Max von dem Borne (1879), Haack (1872), and Jacobi (in the *Hauussischeer Magazin* for 1763—believed to be the earliest printed notice of modern fish-culture), Nicklas (1880), Vogt (1875), Benecke, Dalmer, and Von dem Borne (1886); also the annual Bulletins and Reports of the United States Fish Commission, and the Bulletins de la Société d'Acclimatation de France.

Piscina (named from the swimming-pond in the old Roman baths), in Catholic churches, a shallow stone basin with a drain leading directly to the earth, into which the priest washes his hands, and rinses the chalice at the end of the celebration of mass. In England it is almost invariably placed on the south side of the choir, at a convenient height.

Piscis, a walled town of Bohemia, stands on an alluvial of the Moldan, 84 miles by rail S. by W. of Prague, and has iron and brass works, and manufactures of paper, boots, hats, &c. Pop. 10,596.

Plisia, a name that seems to have applied generally to the mountains immediately to the east of the Lower Jordan, identical with, or closely allied to, a part of the mountains of Asamir (Deut. xxxii. 49; xxxiv. 1), one of the summits of which is Mount Nebo (the modern Neba), 2644 feet above the level of the Mediterranean. From this point Moses enjoyed his glimpse of the Promised Land, in early spring. It is not the highest point among the spurs which here run out from the Moabite plateau, but Major Conder points out that it is the nearest ridge to the Israelite camp in the plain of Shittim. He describes the way to the east as shut in but two miles off by the side of the Moabite plateau, and to the south as closed five miles off by a long ridge, but that to the west as including all the Judean watershed, and in clear weather all Samaria and Lower Galilee. The Tiberias and the coast of Gilboa The Sea of Galilee and Hermon are shut out by the lofty range of Pentiel (Jebel Oskh’i) in Gilead, while the western watershed of Judea and Samaria makes it impossible to see the waters of the Mediterranean; but below to the south-west the northern half of the Dead Sea is seen, between the two branches of Engedi, beyond which stretches the dreary desert of Judah. The burial-place of Moses is unknown, but may have been, suggests Conder, in the terrible gorge of the Zerka M’ain, on the south side of the cliff of Peor, or Minyeh, the Callilhoe of the tyrant Herod’s days. Its old Hebrew name appears to have been Nehaliel (‘the valley of God’).

Of the three tribulations from which Bahamid watched the encampment of Israel, Conder makes the first Banath-Baal (Masbubiyekh), a high ridge separated from Nebo by a deep valley; the second, the ridge of Nebo itself; the third, the top of Peor, over against Jeshimon, a cliff called Minyeh.

Pishin, a district of Southern Afghanistan, just north of Quetta, which has been governed by a political agent of the Governor-general of India since 1878. The British occupied it on account of its great strategical importance; it is the meeting-place of several roads, practicable for troops but not for wheeled carriages, leading from Sind and Punjab to Kandahar. The district—area, 300 sq. m.; elevation, 5000 feet—consists of alluvial valleys separated by ranges of hills, the whole sloping south-west, and surrounded by mountain-chains that reach in north and south 11,000 feet. The people, partly settled, partly nomad, grow wheat, barley, rice, grain, milk, honey, water-melons, and musk-melons, and trade in horses to India. Pop. 60,000. A branch of the Indus valley line traverses the principal valley.

Pisidia, one of the ancient divisions of Asia Minor, lay on the south, separated from the sea by the narrow strip of Pamphylia, and having Phrygia on the north, Isauria on the east, and Lycia on the south-west. Traversed by the main chain of the Taurus, it is a mountainous region, with an insup- pitable climate. The people, a race of hardy and lawless mountaineers, were greatly given to predatory expeditions, and do not seem to have paid any regular obedience to the various oriental and other conquering races up to the Roman period. In the Roman supremacy there were several prosperous cities, as Sagalassus, Antioch, Sele, Ternussen. The boundaries of the province varied at different periods.

Pisistratus (Gr. *Pisistratos*), a famoustron of Athens, was born about 600 B.C. At first he co-operated with his kinsman, the famous Solon, and in the war against the Megarians acquired considerable military distinction; but afterwards, when probably his ambitious views had become more matured, he came forward as the leader of one of the three parties into which Attica was then divided—the *Demose* (population the islands), chiefly a labouring population, jealous of the rich, and enger for equality of political privileges. Driving into the market-place of Athens one day, and exhibiting certain self-inflicted wounds, he called upon the people to protect him against his and their enemies; and, a general assembly of the citizens being summoned, a partisan proposed to allow him a bodyguard of fifty men. The measure was carried in spite of the strenuous opposition of Solon. Gradually Pisistratus increased the number, and in 500 B.C., when the Philistines had conquered the Acropolis. The citizens, in general, seem to have tacitly sanctioned this high-handed act. Megacles and the Aleonomidae—the heads of the rich aristocratic party—fled from the city, but returned in 554 and drove Pisistratus into exile in Elbe (552). Supported by Thibes and Argos, he was able in 541 to sail with a strong force, landed in Attica at Marathon, and marched on the capital. His partisans hurried to swell his ranks. At Pallas he encountered his opponents, and completely defeated them, but used his vic- tory with admirable moderation. When he entered the city no further resistance was made, and he resumed the sovereignty at once. He lived for sixteen years afterwards in undisturbed possess- sions of power, dying 527 B.C., and transmitting his
supremacy to his sons, Hipparis and Hipparchus, known as the Pisistratidae. Although the precautionary measures he adopted to establish his authority involved at first a resolute and stringent policy, yet no sooner had he placed himself out of danger than he began to display that wonderful tact, moderation, and sympathetic appreciation of the wishes of the Athenians that have won him the praise of all later writers. Firmly, and not harshly, enforced obedience to the laws of Solon; emptied the city of its poorest citizens, and made them agriculturists, supplying such as had no resources with cattle and seed; secured provisions for old and disabled soldiers; bestowed greater care and solicitude of the religious festivity of the Atticans; encouraged literature more than any Athenian had ever done before—it is to Pisistratus, or to the poets, scholars, and priests about him, that we owe, for example, the first complete edition of Homer; and, like his still more brilliant successor in the following century, Ptolemy, he adorned Athens with many of its most beautiful buildings, such as the Lyceum, temples to the Pythian Apollo and the Olympic Zeus, &c. See works on Pisistratus by Flach (1885) and Töpffer (1886).

Pisolite (Gr. 'pea-stone'), a concretionary limestone, differing from oolite in having the particles as large as peas.

Pistacia, a genus of trees of the natural order Anacardiaceae, having handsome flowers without petals, and a dry drupe with a bony stone. The Pistacia or Pistachio tree (P. vera) is a small tree of about 20 feet high, a native of Persia and Syria, but now cultivated in all the parts of the south of Europe and north of Africa, and in many places naturalised. It has alternate leaves, with about two pair of oval leaflets, and an odd one, flowers in racemes, fruit ovate, and about the size of an olive. The stone or nut splits into two valves when ripe; the kernel, which is of a bright green colour, is very oleaginous, of a delicate flavour, and in its properties resembles more in the natives of sweet almonds. In the south of Europe and in the East Pistachio Nuts are much esteemed; but as they very readily become rancid they are little exported to other countries. They are sometimes called Green Almonds. Oil is expressed from them for culinary and medicinal purposes. If the male tree is allowed to five or six fertile ones. The tree produces flowers and even fruit readily enough in the south of England but the summers are not warm enough to ripen the fruit, and the tree is apt to be destroyed by a severe frost. The Mastictree, or Lentisk (P. lentiscus), yields the gum-resin called Mastic (q.v.). It is a native of the countries around the Mediterranean. The Turpentine-tree (P. terebinthus) yields the Turpentine (q.v.), known in commerce as Cyprus Turpentine, Chian Turpentine, or Sea Turpentine, which is of a consistency somewhat like that of wax. A gummy resin, flowcolour, an agreeable odour, and a mild taste, and in its properties resembles the turpentine of the Confiers, but is free from acidity. It is obtained by making incisions in the trees, and placing stones for the turpentine to flow upon, from which it is scraped in the morning, before it is liquefied again by the heat of the sun. The tree is about 30 or 35 feet in height, and has pineate leaves, of about three pair of leaflets and an odd one, the flowers in compound racemes, the fruit nearly globular. The kernel of the fruit is maganous and pleasant. The Batoum Tree (P. atlantica), a round-headed tree about 40 feet in height, a native of the north of Africa, produces a fruit much used by the Arabs; and a gum-resin of pleasant aromatic smell and agreeable taste, which exudes from its stem and branches, is chewed to clean the teeth and impart a pleasant smell to the breath. The fragrant oil of the kernels of P. ocyanus, so identified with the Chian of Cochin-China, is used there to perfume ointments.

Pistil, that part of the Flower (q.v.) which, after flowering is over, is developed into the fruit. See FRUIT.

Pistoia (anc. Pistoria), a town of Italy, stands 21 miles by rail NW. of Florence, on a spur of the Apennines. Its streets are thoroughly Tuscany, and it is surrounded with walls, pierced by five gates, and has a citadel. The chief buildings are the cathedral of San Jacopo (12th and 13th centuries), containing a magnificent altar of silver (1280-1405) and several good pictures; the church of St Bartholomew, with a fine white marble pulpit by Guido di Cémoro; and St Andrea, with Giovanni Pisano's pulpit (1291); St John, with a font by Giovanni Pisano and terra-cottas by Andrea della Robbia; the 14th-century communal palace, and other palaces. The principal manufactures are iron and steel wares, agricultural implements, paper, oil, and silk. But the town has the credit of having invented fireworks. The town was given them its name in the form pista. Here Catiline was defeated in 62 B.C. The town was conquered by Florence and Lucca in 1306. Pop. 21,500.

Pistol is the smallest description of Firearms (q.v.). See also REVOLVER.

Pistole, a gold coin formerly current in Spain and France. It is said to have been current to about eleven old French livres, though till about 1730 it was merely an irregular piece of gold. Its value varied somewhat at different times and in different countries, usually being between fifteen and sixteen shillings. The gold pistoles once current in parts of Germany were in most cases merely convenient multiples of the ordinary thaler and golden. The Louis d'or was intended to take in France the same place as the pistole in Spain.

Pita-hemp, one of the names of the Agave fibre. See Fibrous Substances.

Pitaka, a division of the Buddhists' sacred literature; the tripitaka meaning the three great divisions of their canonical works, the Abhidharma, the Vinaya, or Discipline, and Sutta (aphorisms in prose), and collectively, therefore, the whole Buddhist code.

Pit and Gallows, a rendering of the grant of capital jurisdiction (eun usus et foro) made to vassals by the crown in feudal times. Malefactors were usually hanged on the gallows (foro); women were hanged in a ditch or well (foeso). See Baron, Drowning.

Pitaval, François Gayot de (1673–1743), compiler of the famous collection of Causes Célèbres (q.v.), served in the army, but became an advocate, and was known as an industrious and painstaking compiler. Of his great work there have been numerous abridgments, continuations, and translations; and his name has become consfused with the collecting of criminal cases that a similar work, published by various editors in Leipzig in 1843 and succeeding years, was called Der Neue Pitaval (2d ed. 36 vols. 1857–72; new series, 1866 et seq.).

Pitcairn, Robert (1792–1855), editor of the invaluable collection of Criminal Trials in Scotland from 1750 to 1824 (4 vols. 1850). He was joint clerk and post in the Register House at Edinburgh. He was an active member of the Bannatyne Club, and secretary of the Calvin Translation Society (founded 1843).

Pitcairne, Archibald, physician and satirist, was born at Edinburgh, 25th December 1632. He studied first theology and then law at the univer-
sity of his native city; but having gone to France in ill-health, made final choice of medicine as his life study, completing a distinguished course at Paris. He practised with success in Edinburgh till 1892, when the fame of his treatise on Harvey's discovery of the circulation of the blood secured him a call to Leyden as professor. Here he remained only a short while, lecturing on his celebrated work published as Elementa Medicae Physico-Mathematica (1718). He returned to Edinburgh to become one of the most famous physicians of his time: producing also Dissertationes Medicas (1701). For he was even more notorious as a Jacobite, an Episcopalian, a satirist, than for the medical things, and, according to his opponents, as an atheist and sceptic at religion. The Assembly is a comedy in ridiculing of the General Assembly of the kirk; and Babel, or the Assembly (1692), is a poem with the same aim. His Latin verses, some of which were republished by Ruddiman in 1725, are creditable. He died 20th October 1713.

Pitcairn Island, a solitary island in the Pacific Ocean, between Australia and South America, in 25° 3′ S. lat. and 130° 8′ W. long., measures 23 miles by 1 mile. It was discovered by Carteret in 1767, and at that time uninhabited, a fact unimpeachable, though it is certain that there had been inhabited at one time. In 1768 it was taken possession of by nine of the mutineers of H.M.S. Bounty (see Bligh), with six Tahitian men and a dozen women, the ring-leader being called Christian. Four years later the native men one was murdered and all the women were exterminated by Alexander Smith, who afterwards assumed the name of John Adams. Thereupon the women, in revenge, murdered all the Tahitian men. According to another account, the white men and the Tahitians made war on each other; the Tahitians killed only two Englishmen and left alive. Certainly it is that at the end of ten years John Adams was left alone, with eight or nine women and several children; and from them the present inhabitants (126 in 1890) are descended. Adams, changed by these tragic adventures, and sobered by his responsibilities, set about the education of his companions in Christian principles. The little colony was unknown to the world until 1808, when it was 'discovered' by Captain Folger of the American sealing ship Topaz; the first British vessel to visit it did not arrive until 1814. The British were visited again in 1825 and 1830, and in 1831, as their numbers had rapidly increased (to 87), they were at their own request removed to Tahiti by the British government. But, disgruntled by the immorality and other undesirable customs of their Tahitian relatives, the most of them came back to Pitcairn Island after about nine months, in a vessel chartered by themselves. The island was annexed to Britain in 1839. Nearly 200 of the islanders were transferred to Norfolk Island in 1856, but a number of others returned. Pitcairn Island enjoys a lovely climate; its mountainous surface reaches 1008 feet in Outlook Ridge; the soil is fertile, and produces yams, cocoyams, sweet potatoes, bananas, &c. The people are degenerating, from intermarriage and their being almost inarticulate. The chief occupations are fishing and whaling.

See Sir J. Barrow, Motions of the Bounty (1831); Lady Belcher, Mutineers of the Bounty (1750); T. B. Murray, Pitcairn Island (1854; new ed. 1885); Ross Amelia Young (a native), The Story of Pitcairn Island (1890).

Pitch, the degree of acuteness of musical sounds. A musical sound is produced by a series of vibrations recurring on the ear at precisely equal intervals, the greater the number of vibrations in a given time the more acute or higher is the pitch (see SOUND). The pitch of musical instruments is adjusted by means of a tuning-fork, consisting of two prongs springing out of a handle, to make the vibrations of a given air more or less uniform (C = 498 to 515 vibrations per second); but since then, owing mainly to the aid of wind-instrument makers to obtain greater brilliance of tone, it has constantly been rising, to the detriment of other sounds. Nearly all modern orchestras have adopted a uniform (C = 531) as the standard. In 1891 the American piano-manufacturers agreed to adopt French pitch. An effort towards uniformity of pitch in Great Britain, made in 1859-69 by the Society of Arts, and a subsequent attempt initiated by the Royal Academy of Music in 1885, had no practical result. Most British orchestras continue to play at the higher pitch known as Parisian pitch, while in music not orchestral, and with vocalists generally, a pitch about the French is used. The main obstacle to the lowering of pitch is the expense of new wind-instruments, it being impossible to lower the old ones so to great an extent. See A. J. Ellis, History of Musical Pitch, reprinted from the Journal of the Society of Arts, 1880, and given in abstract in Nature, vol. xxi.

Pitcher-plant. See Insectivorous Plants.
PITCH

Pithecëus (Gr., 'ape'), a name formerly used by zoologists for various groups of apes and monkeys. See SAKL.

Pithom, one of the store-cities of the children of Israel built for Pharaoh (Exod. i. 11), concluded from the conclusion of M. Naville with the deserted Arabic village Tell El-Maskhuta, on the Fresh-water Canal and railway line from Cairo to Ismailia, about half-way between Ismailia and Tell El-Kebir. See Naville's Store City of Pithom (1883).

Pitman, Sir Isaac, founder of the Pitman system of Shorthand (q.v.), who was knighted in 1894, was born at Trowbridge, Wilts., 4th January 1813. His father, a factory overseer and afterwards cloth manufacturer, was superintendent of the poet Crabbe's Sunday-school. Young Pitman, a studious and religiously disposed youth, was for a time a clerk, and after some preliminary training taught a school at Barton-on-Humber (1832-36) and at Wotton-under-Edge, where he turned his attention to the popularising of shorthand, and issued through Bagster his Stenographic Sound Hand (1837). Copies of his second edition were put into circulation simultaneously with the introduction of the penny post in 1840. Dissuised from Wotton and Bicester (the scene of his early popularising of the Church, he conducted a school at Bath (1839-43). Henceforward his career is the history of the development of shorthand and spelling reform. He wrote, travelled, and lectured in its interest, his working day commonly lasting from 6 A.M. till 10 P.M., and away at the same time for meals and relaxation. In 1842 he brought out the Phyenic Journal, with which the late A. J. Ellis was for a time associated. In 1845 premises were opened in London for the sale of Pitman's publications. In recognition of his exertions he was presented with £250 and a marble timepiece in 1882, and at a phonographic jubilee meeting in 1887 was presented with a marble bust of himself. He died 22d January 1897. In his early days he spent much of his narrow income in the cause. Up till 1890 he had issued from his Phyenic Institute, South, London, his shorthand Phonographic Teacher was selling at the rate of 150,000 annually. From the date of issue 1,370,000 had been sold. There were also eighty-four shorthand associations, and a National Phonographic Society, whilst the subject had been recognised in the Education Code (1890) and the Technical Instruction Act of 1889, so that Pitman's labours of more than half a century have been crowned with success. About 95 per cent. of reporters in England, the colonies, and America use Pitman's system, which has been adapted to the Welsh, French, German, Italian, Spanish, Dutch, Japanese, and Malayasian languages. It is estimated that its practitioners all over the world number above half a million. See T. A. Reed's Biography of Isaac Pitman (1890).

Pitron Bark. See CARIBBER BANK.

Pitrat, Jean Baptiste, was born at Champforsqel, near Autun, August 31, 1812, entered the order of St Benedict, and devoted himself to historical studies in the abbey of Solesmes. In 1888 he was sent by the pope to Russia to study the Slavonic liturgy, was created a cardinal-priest in March 1863, librarian of the Vatican in 1869, and Cardinal-bishop of Frascati in 1879. He died February 3, 1889. His works include Histoire du Sacre de Jésus (1842), Procédé de la Nature, vol. ii, iii., liii, lii., and in the present work the articles ANTHROPOID APES, MAN, SKULL.

PITRA

Pich Lake. See TRINIDAD.

Pitchstone, or Retinite, an acid volcanic glass, dark green, reddish brown, yellow, dark blue, or black, and occasionally showing a streaked or clouded appearance. It has a pitch-like or greasy lustre, and a very conchoidal fracture, and is translucent on thin edges. It is usually rich in microโรites, and often contains crystalline granules and crystals of felspar, pyroxene, hornblende, biotite, and quartz. Now and again it shows pellite and spherulitic structures. When composed of sandstone it is mantled with sand, and abundantly present in the rock it is termed Pitchstone Porphyry. It occurs in the form of dykes and also as lava-flows. The name pitchstone has sometimes been given to the darker varieties of meiolite, a form of opal.

Pith, or MEDULLA, is the central cylinder of tissue in the stems of Dicotyledons and Gymnosperms. In all plants where it is found it is continuous in the young state. In older plants it may be continuous, as in the elder, oak, &c., in the form of transverse discs, as in the walnut, or wanting in the internodes, as in hemlock, &c. In very young stems it is composed of small cells filled with protoplasm and cell-sap, and takes part in the conduction of nutritive substances throughout the plant. The cell-walls usually remain very thin, the protoplasm is soon all used up within the cells, and their further growth ceases. Examined microscopically, pith cells are usually polygonal in transverse section, while they are rectangular in longitudinal section, and not much longer than broad. The ring of wood immediately surrounding the pith consists largely of spiral and annular vessels, and is known as the medullary sheath. The pith is connected with the cortex and bast by the medullary rays, which are composed of cells similar to those of the pith, and which convey sap to the inner parts of the stem. In the early life of most trees the pith serves as a storehouse for starch and other reserve substances; but as the tree increases in age the inner wood is invaded by wood, communication with the cortex and bast is physiologically obstructed, and the pith cells become dry and full of air.

Pithecanthropus erectus ('erect ape-man'), the name given by Dr Eugene Dubois, of the Dutch army medical service, to the animal remains which he discovered on the shore of Java. These consist of the upper part of a cranium, a left femur, and two molar teeth, and were found in 1891-2 on the left bank of the Bengawan river, near Trinil, during explorations conducted for the government of the Dutch Indies. The cranium and teeth were found close together, and the femur a few yards away and a year afterwards; but Dr Dubois believes them to belong to the same skeleton, and to such as could only have belonged to an animal midway between man and the higher apes, and of pleistocene age. The cranium is in length and size between the normal human and the gorilla's skull, and rather closely resembles that of a microcephalous idiot. The find has given rise to much discussion and difference of opinion; many authorities holding that the femur and cranium have not been proved to belong to the same skeleton, and the while the femur is undoubtedly human, the cranium is of a very low human type; others wholly or partly agree with Dr Dubois. The diversity of opinion extends to the teeth, which are large and powerful.

See the discoverer's monograph, Pithecanthropus erectus (Batavia, 1891), in German; the paper read by Dr Dubois to the Royal Dutch Institute, for the Advancement of Natural Science, vol. ii, iii., liii, liii., and in the present work the articles ANTHROPOID APES, MAN, SKULL.
Pitt, William, ‘the younger,’ son of the great Earl of Chatham and of Lady Hester Grenville, was born at Hayes, near Bromley, in Kent, on 28th May 1759. At the time of his birth his father was still in the House of Commons and in the very zenith of his fame, and the future statesman grew up amid admiring and anointing. He was well fitted to foster that political ambition which was to be the guiding and almost the sole impulse of his life. His constitution in boyhood seemed very weak; he was never sent to school, but his education advanced self-motivated and under a father’s eye, and by the age of fourteen he was able to enter Cambridge when only fourteen.

He was then a shy, reserved boy of exceedingly precocious talents, of irreproachable morals, and of regular and studious habits, little drawn to college societies and amusements, and already distinguished by a rare self-control and concentration of purpose. From his earliest youth political life was placed before him as his ideal, and all his studies converged to that end. He became an excellent classical scholar, but he valued the classical writers mainly as a school of language and of taste; and it was observed more particularly in his youth than later that he had a peculiar facility in the styles, noted down every just or forcible expression, and compared the opposite speeches on the same subject, observing how each speaker met or evaded the arguments of his opponent. Like many others he found in Locke a great master of clear and accurate thinking. His father supervised his studies with much care, and it was remembered that he specially recommended to him the sermons of Barrow as models of style and reasoning, and the histories of Polybius and Thucydides as fountains of political wisdom; that he got him a collection by making him declaim the grandest poetry in Shakespeare and the speeches of the fallen angels in the Paradise Lost; and that he exercised him in fluency by accustoming him to translate into flowing English long passages from the classical writers. To this last impartation Pitte largely ascribed that amazing command of choice and accurate English in which he surpassed all his contemporaries.

When little more than a boy he was an attentive and discriminating listener to the debates in Parliament. He became thoroughly familiar with political and philosophical questions, and together with his brother-in-law, Lord Mahon, he supported his father into the House of Lords on the 7th April 1778 on that memorable occasion when Chatham delivered his last speech against the surrender of America, and that oration which was his crowning stroke. Pitt left with a patrimony of less than £300 a year. He was called to the bar in the June of 1780, and went on the Western Circuit, but in September parliament was dissolved, and he at once threw himself into politics. He stood for Cambridge University, but found himself at the bottom of the poll; but Sir James Lowther gave him a seat for his pocket borough of Appleby, and Pitt, in opposition to the ministry, entered the House of Commons on 23rd January 1781.

He came into the House bearing a name which was beyond all others revered by Englishmen, with the advantage of being in no way mixed up with the calamitous American war, and with talents that had already acquired an extraordinary maturity. The reputation of the ministry of Lord Rockingham was tottering to its fall, crushed by the disasters in America, and confronted by an opposition which consisted of the Old Whigs who followed Rockingham, among whom Fox and Burke were conspicuously attached, and of the new Whigs, who were attached to the fortunes of Chatham, and who were chiefly represented by Shelburne, Camden, and Barré. Pitt lost no time in throwing himself
into the fray. He spoke on the 26th February with brilliant success in defence of Burke's Bill for Economical reform, and on several successive occasions he assailed the falling ministry. He demanded an alliance with the Commons, the severe influence of the crown with extreme violence, but he refused to throw in his lot irrevocably with the party of the opposition, and shortly before the fall of North he publicly declared that he could not expect to bear a part in the coming ministry, as he 'would never accept a subordinate position.' The words are said to have escaped from him in the heat of the debate, and the House was startled and a little amused at the arrogance of a young man who was not twenty-three, who was absolutely without official experience, and who had been little more than a private member of parliament, and he would accept no office except in the Cabinet.

But Pitt had attained a position that placed him far above lasting ridicule. Fox spoke of him as already one of the first men in parliament. Burke said of him that he was not a chip of the old block, but a new Adversary. It was said that he had shown logical powers that made men doubt whether he might not prove superior even to Fox; and when upon the resignation of North in March 1782 a ministry was formed under the leadership of Rockingham, combining the two secretaries of state, Pitt calmly refused his pledge and refused several offers, among others the Vice-treasurership of Ireland with a salary of £5000 a year. He gave, however, a general and cordial support to the new ministers, but he at the same time brought forward the question of parliamentary reform on which they were profoundly divided. It was a question which fell naturally to him, for his father had been one of the first to urge it. On the 7th May he moved, in a speech of great brilliancy, for a select committee to inquire into the state of the representation, and was only defeated by 161 to 141. He soon afterwards supported a measure of Sawbridge for shortening the duration of parliament, and a measure of Lord Mahon for preventing bribery at elections.

A close personal and political connection about this time grew up between Pitt and Henry Dundas, whose strong and active mind proved of great importance to the career of Pitt. Dundas had none of the intellectual brilliancy or of the moral dignity of the younger statesman, but he had one of the best political judgments of his time, he had great talents both for business and for debate, and his sanguine notion of himself as the judge of the characters of men—a gift in which Pitt through his whole life was somewhat wanting.

The Rockingham ministry lasted only for three months. The king detested it; it was from the first profoundly divided, and a litter personal and political animosity had broken out between Charles Fox and Lord Shelburne, its two most conspicuous members. On 1st July 1782 Lord Rockingham died, and the question of leadership at once broke up the party. Fox insisted on the leadership of the Duke of Portland, a wealthy and respectable, but perfectly undistinguished nobleman, who was then Lord-lieutenant of Ireland. The king gave the post of First Lord of the Treasury to Shelburne, who had an incomparably higher political position, and who had been a favourite friend and colleague of Chatham, though there were features in his character that excited the envy and distrust of Fox, with a considerable section of the Rockingham Whigs, at once resigned, and Pitt entered the Cabinet as Chancellor of the Exchequer in the reconstructed ministry. Public opinion generally blamed Fox, and some of the consequences of his resignation was that the House of Commons was divided into three distinct parties. There was the party of Fox, the party of North, and the party of the government, and no one of them could command a clear majority. A coalition of some sort was unavoidable. Shelburne proposed an alliance with North, but Pitt positively refused to have any connection with the statesman whom he deemed responsible for the American war. Peace was not yet attained, but the negotiations which had been pursued by the preceding ministry were steadily pushed on. Provisonsal articles of peace between England and the United States were signed in November 1782, and preliminary articles with France and Spain in the following January, while a truce was established with Holland, and the first steps were taken towards a very liberal commercial treaty with those states. Pitt bore a leading part in the debates in parliament, and his reputation steadily rose, but the Shelburne ministry was weak, divided, and short-lived. The peace following a disastrous war necessarily involved sacrifices that were profoundly unpopular, and the character of Shelburne aggravated the evil effects that had already appeared. Several resignations took place, but Pitt stood unshaken by his chief, and endeavoured without success to induce Fox to rejoin the ministry. Fox, however, declared that he would never again serve any ministry with Shelburne for its head, notwithstanding the influence of the king and of the country, he united with the very statesman whose expulsion from public power had been for years the main object of his policy, and whom he had repeatedly threatened with impeachment. North, irritated at the ostracism with which he had been treated, entered into the coalition. Two factious votes of censure directed against the peace were carried through the Commons by majorities of 16 and 17, and on 24th February 1783 Shelburne resigned.

Pitt had displayed the most splendid parliamentary talents in the discussions that preceded the fall of the ministry, and although he could not overthow the compact weight of parliamentary influence opposed to him, he profoundly moved the country and placed his own position beyond dispute. On the fall of the Shelburne ministry, the king had no hesitation in placing the yoke of the coalition, implored the young statesman to accept the leadership, and gave him an absolute authority to name his colleagues. It was a dazzling offer, and Pitt was not yet twenty-four, but he already possessed a judgment and self-command which is the true coin of a combination such brilliancy and such courage, and he saw clearly that the moment of triumph had not yet come. After a long struggle and many abortive efforts the king was obliged to yield, and on the 21 April the coalition ministry was formed with the Duke of Portland as First Lord of the Treasury, and Fox and North as joint Secretaries of State. It commanded a large majority of the votes, and included a great preponderance of the ability in the House of Commons, but the king viewed it with a dejection amounting to loathing, and the nation was profoundly scandalised by the alliance on which it rested. Pitt was offered his old post of Chancellor of the Exchequer, which he peremptorily refused. As leader of the opposition, he brought forward, in the form of resolutions, an elaborate programme of parliamentary reform, for an increase of the country members. He was defeated by 203 to 149, but he at least succeeded in bringing Fox and North into direct collision. He brought forward another important measure for the reform of abuses in the public offices, which passed the Commons, but his measure rejected by the Lords which was carried by the new ministry differed very little from that which they had
censured when in opposition; and very soon the bill of the government for subverting in some important respects the charter of the East India Company and reorganising the government of India, produced another great change in the disposition of power.

The feature of the scheme which chiefly excited indignation and alarm was the creation of an existing legislature of a new supreme body in England, consisting of seven commissioners who were to be immovable except by an address from either house for four years, and who were unlikely that period to have an absolute control of the patronage of India. It was contended that this measure would give the party who were now in power an amount of patronage which would enable them to overbalance the influence of the crown, dominate the parliament, and control succeeding administrations. These objections were brought forward by Pitt with great power, but with extreme exaggeration, and the king and the nation were speedily alarmed. The Indus Bill passed by large majorities through the Commons, but when it came into the House of Lords the king, as he contended, Lord Temple to say that he would consider any man his enemy who voted for the bill. The communication produced an immediate effect. The bill was rejected in the Lords by 95 to 76; the ministry resigned. In the House of Commons the Commons supported them by large majorities; but the king peremptorily dismissed them on 18th December 1783, and next day it was announced that Pitt had been called to the head of affairs as Chancellor of the Exchequer and First Lord of the Treasury.

Pitt had already abundantly displayed his parliametary ability, his judgment, and his discretion. He was now to display in the highest degree his courage. In the eyes of nearly all the best judges in England his position was a hopeless one, and his administration was likely to be even more brief than the three which had preceded it. There was a majority of more than a hundred against him in the Commons, and the parliamentary influence behind it was so great that an immediate dissolution must have been disastrous. He was called to office by the constitution and interference, on the part of the king, and every day which he remained in office under the censure of the House of Commons added to the falseness of his position. Temple, on whom he had greatly relied, threw up the great responsibility which he had accepted, and in the House of Commons Pitt was himself at this time the only cabinet minister, while Dundas was the only considerable minister who supported him against the united attacks of North, Fox, Burke, and Sheridan. But Pitt fought his battle with a skill and a resolution that have never been surpassed in parliamentary history. A long succession of hostile votes was carried, but they failed to drive him from office, and soon unequivocal signs appeared that the country was with him. The magnanimity with which at this critical period he refused to take for himself a great sinecure office which fell vacant added greatly to his popularity. Addresses in his favour poured in from all the leading corporations in the country. The majorities against him grew steadily smaller. At last, on 22nd March 1784, the long-deferred blow was struck. Parliament was dissolved, and an election ensued which swept away nearly 100 members of the opposition, made Pitt one of the most powerful ministers in all English history, and prepared the way for a ministry which lasted, with few months' intermission, for no less than twenty years.

In this great and powerful ministry English political life assumed much of its modern aspect. The House of Commons acquired a new importance in the constitution, the people a new control over its proceedings, and the First Lord of the Treasury complete ascendancy in the government. The system of 'king's friends' controlling the ministry was finally ended, and the first Lord Thurlow, attempted to perpetuate it, he was peremptorily dismissed. The skilful management of the regency question established the right of parliament to provide for the exercise of supreme power during the incapacity of the king. Direct elections for the parliament was the result. Great numbers of sincere places were abolished, and great reforms were introduced into the system of collecting the revenue and issuing public loans. The government of India was reorganised on the system of a double government, which continued with little change till the abolition of the East India Company in 1858. The whole system of taxation and of trade duties was thoroughly revised, and no minister since Walpole had approached Pitt in his complete competence in dealing with trade questions. The finances of the country, which had been extremely disorganised by the American war, became once more flourishing. A commercial treaty, based upon more enlightened commercial doctrines than any English statesman, except Shelburne, had yet adopted, was negotiated with oblivion. England, Prussia, and Holland contributed largely to terminate the wars between Sweden and Denmark and between the emperor and the Turks, though it met with a mortifying failure in its dealings with Russia. Pitt's love of peace was very sincere, but the influence of England in European councils was greatly under his ministry, and he showed much decision and tact in extricating England from a dangerous complicity with the ambitious designs of her Prussian ally. Up to the time of the French Revolution there was no decline in his ascendency, his popularity, and his success.

A few adverse criticisms, however, may be justly made. He cast aside too lightly on the first serious opposition parliamentary reform and the abolition of the slave-trade, and it became evident to good men of all parties that Pitt was a man of very little ability, and was ready to sacrifice great causes with which he had sincerely sympathised and which he might have carried, rather than raise an opposition that might imperil his ascendency. His once famous Sinking Fund is now universally recognised to have been thoroughly unproductive in its principle; and in the latter part of his career it led him to the absurdity of borrowing largely at high interest in order to pay off a debt that had been contracted at low interest. His attempt to establish free trade between England and Ireland failed and for the great uncertainty of his policy towards the Irish Catholics. The great evils which grew up in England in his time in connection with the sudden development of the factory system appear never to have attracted his attention or effort to mitigate them. He created peerages with extreme lavishness and with very little regard to merit, and although his patronage was not positively corrupt, few ministers have
shown themselves more indifferent to the higher interests of literature, science, and art.

When the French Revolution broke out his policy was one of absolute neutrality towards the contending parties, and this neutrality be most fatal almost to the eye of the great war he in understanding the character and the supreme importance of the Revolution. He believed that it was merely a passing disturbance, and that its principal effect would be to deprive France for some years of all serious influence in European affairs, and soon after with the transverse genius of Napoleon, Pitt, whilst he gained the profound swiftness of the war and the efficacy of his sinking fund, led him into the great error of raising his war expenses in the first stages of the war almost wholly by loans, and thus laying the foundation of an enormous increase of debt. His military enterprises were badly planned, badly executed, and he exhausted none of his father's skill in discovering and bringing forward military talent. For some years it is true his ascendency in parliament continued to increase, the great Whig schism of 1784 and the secession of Fox reduced the opposition to utter insignificance of which even he in his domestic measures Pitt was no longer fortunate. Through fear of the revolutionary spirit which had infected some portions of the population, he was led into repressive measures very little in harmony with his earlier career. Corn had risen to famine price, and great distress prevailed, and the government attempted to meet it by very ill-conceived relaxations of the poor-laws—by levying rates for the purpose of increasing wages, and by granting parochial relief in proportion to the number of children in a family, and thus offering a direct premium to have children. In Ireland, where disaffection was steadily growing, and Pitt tried to win the Catholics by measures of conciliation, and especially by the concession of the sufrage; but the opposition of the king, divided councils, and the vacillation of his own mind impaired his policy, and the injudicious recall at a very critical moment of a popular viceroy contributed largely to the savage rebellion of 1798. He then tried to place Irish affairs on a sound basis by a legislative union which was to be followed by Catholic emancipation, the payment of the priests, and the teaching of the deaf, but his last measure was carried by very corrupt means, but the king, who had not been informed of the ultimate intentions of his minister, declared himself inexorably opposed to Catholic emancipation, which he deemed inconsistent with his coronation oath. Pitt resigned his office into the hands of his follower Addington in February 1801; but a month later, on hearing that the agitation of the Catholic question had for a time overthrown the tottering intellect of the king, he declared that he would abandon the Catholic question during the remainder of his life, and on the 19th of May 1804 on the understanding that he would not suffer it to be carried. His last ministry was a melancholy and a humiliating one. The war, which had been suspended by the peace of Amiens, had broken out with renewed vehemence. There was great danger of invasion, and Pitt earnestly desired to combine the most eminent men of all parties in the ministry; but the king forbade the admission of Fox. The principal followers of Fox refused to join without their chief, and Lord Grenville and his followers took the same course. Lord Grenville, who was in the head of the Administra- tion, was now completely alienated. A junction with Addington was effect ed, but it lasted only for a short time, and it added little to the strength of the ministry. Dundas, Pitt's oldest friend and colleague, had been lately made Viscount Melbourne. He was placed at the head of the Adminis- tration; but a charge of misappropriating public funds was raised against him, and in 1805 he was driven ignominiously from office. Pitt's own health was now broken. His spirits had sunk; the spell which had once surrounded him had in a great degree passed away, and although the victory of Trafalgar saved England from all immediate danger of invasion, the disasters of Ulm and Austerlitz threw a dark cloud over his closing scene. He died in his forty-seventh year on 23rd January 1806. The House of Commons by a great majority resolved its funeral and a monument in Westminster Abbey.

He was never married, and he never mixed much in general society; but in all his private relations he was pure, amiable, simple, and attractive. He was a warm friend. His temper was very equable, and he was good-humored and kindly. For years he had much ready wit, and he could easily throw off the cares of office, and even join heartily in the games of boys. He maintained to the last his familiarity with the classics, but his serious interests were exclusively political. He only once crossed the Channel, and his absence was wholly untouched by the great contemporary currents of literature and non-political thought. He was not free from the prevailing vice of hard drinking, and he has been justly blamed for having allowed his great indifference to money to degenerate into a culpable carelessness. In 1801 some of his friends subscribed £12,000 towards the payment of his debts, and in the following year he sold Holwood, his country place. But these measures proved wholly insufficient. With no extravagant tastes, with no family to support, with no expenditure of any kind in London, with no source of revenue except the £10,000 a year, he left £400,000 of debt, which was paid by the nation. In public he was cold and repellent, and there was something theatrical in the unvaried dignity of his demeanour; but few men possessed to a higher degree the power of commanding, directing, and controlling, and he inspired the nation with an unbounded confidence both in his character and in his abilities. England has seen no greater parliamentary leader, few greater masters of financial and commercial legislation, and he was one of the first statesmen to adopt the teaching of Adam Smith, and his influence was very diffuse, if it showed little imagination, or depth or originality of thought, it was at least supremely adapted to all the purposes of debate, and it rarely failed in its effect. He was, in a word, a great peace-minister; but in the latter part of his life an evil fate brought him face to face with problems which he never wholly understood and with difficulties which he was little fitted to encounter.

His political life has been written in much detail by Tomlins and by M'Ivor (1804); but his life and the biography of him which has yet appeared is that of Lord Stanhope. Lord Macaulay has made him the subject of a well-known biographical essay, and Mr Goldwin Smith has written two biographies and three monographs by Mr Walford (1860) and Lord Rosebery (1891). The career of Pitt, however, is indissolubly interwoven with the whole English history of his time, and in that connection it may best be studied.
PITTSBURGH

Pittacus, one of the 'Seven Wise Men' (q.v.) of ancient Greece.

Pittenweem, a small seaport of Fife, a royal (since 1542) and parliamentary burgh (St. Andrews group), 3½ miles N.E. of Ely by rail, with fisheries.

There are ruins of a 12th-century priory. Pop. (1891) 1962.

Pittsburgh, officially spelled PITTSBURGH, the second city of Pennsylvania, is located at the junction of the Alleghany and Monongahela rivers, at the west end of the state, and is separated from the Ohio to the south by a distance of 1.5 miles.

The business portion of Pittsburgh is on a plain less than a mile in width, along the rivers, while the hills, commanding delightful views, are covered with handsome residences. In this region, where the prevailing sunny climates and sandstones have been worn away by the rivers to a depth of 500 or 600 feet, the horizontal layers of coal are exposed, and access afforded to the coal seam on the sides of the hills and at the bottom of the valleys to an extent elsewhere unknown; the great Pittsburgh coal layer, 8 feet thick, like a broad black band encircles the city, 300 feet above the river. This coal, which adds so much to the prosperity of Pittsburgh, is unequalled in quality for metallurgical purposes and is easily accessible, particularly on the Monongahela, where for 100 miles the coal outcrops on its banks and is easily transported by barges down the Ohio to Cincinnati, Louisville, New Orleans, and other river ports. Eighty towboats and thousands of barges, boats, and flat are engaged in the coal trade. In 1894 the coal tonnage of the Ohio river amounted to 50,952,000 tons. The same year nearly 8,000,000 tons passed down the Ohio, which amount, added to that sent away by rail or consumed in the city, fully equals two-thirds of the yearly output of bituminous coal for the entire state. On the Monongahela is the celebrooked coke works, which were first organized in 1868 and produced in 1897, 6,915,052 tons of unequaled coking.

Pittsburgh's manufactures include everything which can be made of iron, from a 58-ton gun to nails and tacks; steel in its various applications; all descriptions of glass and glassware; silver and nickel-plated ware; Japan and Britannia ware; pressed tin, brass, bronze; earthenware, crucibles, fire-pots, bricks; furniture, wagons, and carriages; brushes, bellows, mechanical supplies of all kinds; natural-gas fittings, tools for oil and gas wells, &c.

The Carnegie Steel Company, Limited, with a paid-up capital of $23,000,000, manufactures steel rails, billets, armour-plate, &c. The incandescent lamp has been brought to the greatest state of perfection in this city. The petroleum fields around Pittsburgh produced in the past four years 67,903,478 barrels of the highest grade of oil.

The position of Pittsburgh on the eastern border of the great Mississippi river-basin and her facilities for penetrating to every part by river and rail give her great natural advantages for trade and as a depot for exchange and transport and the produce that is manufactured and consumed by her in a market. Four lines of packet ply on the Monongahela and four on the Ohio. Fourteen distinct railroad routes here. The immense volume of trans-continental business passing through Pittsburgh annually is probably excelled by that of no other city except Chicago. Exclusive of freight in transit, the ascertained tonnage handled in 1897 was by rail 36,679,415 tons, and by river 7,318,366 tons, which is by far the greatest tonnage of any city in the United States if not in the world. Pittsburgh has thirty-one national banks, with 2,500 tellers. The total capital and surplus of $34,275,000. The city possesses a good system of public schools, is the seat of a Catholic college, the medical, law, dental, and pharmaceutical departments of the Western University of Pennsylvania, a college for women. Pittsburgh is the site of the world's largest of its kind; it has the largest number of preparatory schools and academies. The Carnegie Institute, to which Mr Andrew Carnegie has already donated two and a half million dollars, stands at the entrance to Schenley Park, and contains a large music hall, an art gallery, a library, and a museum. In the same park, a short distance from the Carnegie buildings, is the Phipps' Conservatory—a gift of Mr Henry Phipps, originally costing $110,000, filled with flowers and plants from every clime. In Highland Park is the coal-tar building, costing $100,000, the gift of several public-spirited citizens. The principal parks are the Schenley—a gift from Mrs Mary E. Schenley—located in the heart of the city, the Herron Hill Park, which commands an extensive view, and Highland Park, beautifully located on the banks of the Allegheny and Monongahela rivers. The two parks are crossed by fifteen bridges, some of them monuments of engineering skill; the heights within the city are reached by eleven inclined railways for freight and passengers, and all parts of the city and suburbs are easily reached by lines of electric cars.

History.—In the early history of America the site of Pittsburgh was a point of great interest, and was familiarly known as the 'Gateway to the West.' Here traders, settlers, and adventurers, who had worked their way from Philadelphia by a chain of forts, congregated, and here flat-boats were built which carried them down the Ohio to the unknown regions beyond. In 1754 a few English traders built a stockade at the point, but were driven away by the French the following April. The latter afterwards replaced the stockade by a fort, which, in honour of the governor of Canada, they called Duquesne. It was near the present outskirts of the city that Braddock (q.v.) was surprised in 1755; and on October 15, 1758, General Grant and his Highlanders overthrew the French near the court-house now stands when they were surrounded by the Indians and nearly exterminated.

The following month, however, General Forbes took possession of what remained of old Fort Duquesne, the French having fled down the Ohio, leaving the buildings in ruins on May 17, 1759. He then built a large and strong fortification, which, in honour of the elder Pitt (see CHATHAM, EARL OF), then prime-minister, they called Fort Pitt. The fort is
said to have cost the English government £60,000. The settlement became the incorporated city of Pittsburgh. Pop. (1810) 4768; (1840) 21,115; (1850) 86,076 (with Birmingham, 121,799); (1880) 156,389; (1890) 288,017; (1910) 321,765.

Pittsburgh, capital of Pennsylvania, on the Susquehanna River, 8 miles by rail N.E. of Wilkesbarre. It is in the centre of a field of anthracite coal, and has extensive mining interests, besides other industries. It is connected by electric trams with Wilkesbarre, Scranton and other cities; and by several bridges with West Pittston. Pop. (1900) 125,565.

Pituitary Body. A rounded body of the size of a small bean situated in the sella turcica in the sphenoid bone on the floor of the cavity of the skull. It contains small cavities lined by epithelium and it possesses many vessels. It derives its name from its having been once supposed to secrete the fluid which is now known to be yielded by the Schneiderian or pituitary membrane of the nostrils (see Nose). It is composed of two parts, the one a downgrowth from the floor of the third ventricle of the brain, the other an upgrowth from the pharynx, from which it has become completely separated. A disease called acromegaly is by some supposed to result from enlargement of this gland.

Pit Villages are collections of earth-caves, dug in the ground and covered with stones, wooden or wattle lids, or clay or sods of turf, and used by prehistoric races or by races at the lowest stages of barbarism. A good example was unearthed during the latter half of the 19th century near St Mary Bourne, north-east of Andover, in north-western Hampshire. The pits are reached by entrance shafts, sloped downwards. The pits themselves are oval or pear-shaped, varying between 22 and 42 feet in length, and are about 12 or 13 feet wide, and 5 feet high, with the fireplace in the centre. Flint and bone implements and rude pottery have been found in them.

Pityriasis (from the Greek word pityron, "brow" or "brow-shaped") is the name given to one of the squamous or scaly diseases of the skin, in which there is a continual throwing off of bran-like scales of epidermis, which are renewed as fast as they are lost. It is most common on the scalp, when it is known as dandruff, and must be treated with weak alkaline lotions, or, if these fail, with diluted white precipitate ointment, provided there is no inflammation. Pityriasis rubra is a severe disease, affecting the whole or almost the whole body, and closely allied to, if not identical with, a severe form of dry Eczema (q.v.). Pityriasis or Tinea versicolor is due to the presence of a parasitic fungus, the Microsporon fuscum; it occurs in the form of irregular yellowish or brownish patches, confined to the parts of the body covered by the clothes. Microscopic examination of the exfoliated scales shows the spores and filaments of the fungus. The treatment consists in, if possible, removing the cause. The best remedy is the application of a saturated watery solution of sulphurous acid gas, or of one of the sulphites dissolved in diluted vinegar, or of white precipitate ointment.

Pius, the name of nine among the Roman pontiffs, of whom the following only appear to call for particular notice.—Pius II., originally known as Aeneas Sylvius, was a member of the noble family of Piccolomini, and was born in 1405 at Consignano near Siena. His early life was stained with moral irregularities, and, like other humanists of his time, he wrote a very large number of books and treatises. He seems to have written at least one loose novel—Loretia and Euryalus. At twenty-six he was employed as secretary to Domenico da Capranica, Bishop of Fermo, at the Council of Basel. He soon developed a genius for diplomacy, and from 1432-35 was employed in missions to Scotland, England, and France. Returning to Basel he sided with the council in its conflict with the pope, and on the election of the antipope, Felix V., was chosen as his secretary. But, having been sent on an embassy to the Emperor Frederick III., he was without difficulty induced to return to Rome, and, by the empire, on several embassies and other missions of importance on behalf of the emperor. Up to this time he had lived a life of unrestrained self-indulgence, but at the age of forty his passions had burned themselves out, and he was able to take orders and make his profession his whole life's occupation—the only means of obtaining a reward adequate to his ambition. He won over Pope Eugenius IV. by the frankness of his apology and earned his gratitude by his adroitness in bringing back to the papacy the allegiance of the neutral German Church. Almost the last act of his pontificate was to make him with his own hands the bishop of Trieste. It was not, however, till the end of 1456 that Aeneas was free to leave the ungenial atmosphere of Germany, Nicholas V. had employed him without rewarding him, but Callistus III. created him a cardinal. On the death of Callistus in 1458 he was elected pope and took the name of Pius II. He possessed a marvellous power of adapting himself to circumstances, and the prolific and shifty intriguer made a most decorous pope. He was embarrassed by contests against Neapolitan and German affairs, and his reign is chiefly memorable for his efforts to organise an armed confederation of Christian princes to resist the progress of the Turkish arms. He died at Ancona, 14th August 1464, his last moments darkened by the failure of his great scheme. Aeneas Sylvius was one of the scholars of his age. His works were published at Basel (1 vol., fol., 1551), and consist chiefly of histories, or historical dissertations and materials of history. The most interesting of his writings, however, are his letters, which throw a vivid light upon their age. These may be found in the collection of a Dutch minister, or in another, compiled, or rather autograph, published under the name of the copyist Gobellinus, and apparently altered by his secretary Campagna.

See Voigt's Life (3 vols., Berlin, 1850-60); also two papers by Bishop Creighton in Macmillan's Magazine, vol. xiv., and vol. ii. (1882) of his History of the Popes during the Reformation.

Pius IV., Giovanni Angelo Medici, was born of humble parents at Milan in 1499, was educated at Bologna, and under Paul III. rose rapidly to be Archbishop of R aggrav, vice-legate of Bologna, and cardinal (1549). He was elected pope at the close of 1559. His reign is chiefly memorable as that in which the protracted deliberations of the Council of Trent were brought to a close. The famous Creed of Pius IV., or Tridentine Creed, was confirmed by a bull dated 28th January 1564. In 1564 he was placed by the Pope in the new, St Charles Borromeo. His Correspondence with the Emperor Maximilian II. has been edited by Schwarz (Paderborn, 1889).

Pius V., originally named Michele Ghislieri, was born of poor parents, in the village of Boville near Alessandria, in 1504, and at the age of fourteen entered the Dominican order. His merit was
recognised by Paul IV., who named him Bishop of Sutri and Nepi in 1556, and cardinal in the following year. His austere temper prompted him as inquisitor-general for Lombardy to employ the most rigorous measures for repressing the Reformed doctrines. Under Pius IV. he was translated to the see of Piacenza, and was chosen cardinal by his successor, January 8, 1566. As pope he laboured to restore discipline and morality at Rome, reduced the expenditure of his court, pro-
hibited bull-fights and other amusements, sup-
pressed prostitution, and regulated the taverns of the city. He introduced the Inquisition and strove to enforce everywhere the disciplinary decrees of the Council of Trent. The whole spirit of his pontificate is most strikingly exhibited in the decree by which he ordered the yearly publica-
tion of the celebrated bull, De Caena Domini (1568)—an attempt to apply to the 16th century the principles and the legislation of Hildebrand.

His impotent bull releasing Queen Elizabeth's subjects from their allegiance (1570) fell harm-
less even upon patriotic English Catholics in a hasty, and was limited by a subsequent bull. The pontificate of Pius V. was the expiration which he organised, with Spain and Venice, against the Turks, and which resulted in the great naval engagement of the Gulf of Lepanto, on 7th October 1571. Pius died in the following May, 1572, and was canonised by Clement XI. in 1712.

Pius VI., originally named Giovanni Angelo Braschi, was born at Cesena, December 27, 1717.

He was selected by Benedict XIV. as his secretary; and under Clement XIII. he was named to several important appointments, which led finally, under Clement XIV., to his elevation to the cardinalate (1773). On the death of Clement XIV, Cardinal Braschi was chosen to succeed him, February 15, 1775. His internal administration was enlightened and judicious. To him Rome owes the drainage of the Pontine Marsh, the improvement of the port of Ancona, the completion of the church of St Peter's, the foundation of the new Museum of the Vatican, and the general improvement and embellishment of the city. Soon after his accession he formed a Council of State, which was presided over by Joseph of Austria and Leopold of Tuscany, whose reforms had swept away much of the papal supremacy. The pope repaired in person to Vienna, but, though received kindly, failed to restrain the emperor from further curtailing his privileges. Soon after came the outbreak of the French Revolution and the confiscation of all church property in France. The pope banished his thunders in vain, and ere long the storm broke upon his own head. The murder of the French political agent Bessivole in a street scuffle at Rome (1792) gave the Directory an excuse for the attack. In 1796 Bonaparte took possession of the Legations, and afterwards of the March of Ancona, and by a threatened advance upon Rome extorted from Pins, in the treaty of Tolentino (10th February 1797), the surrender of these provinces to the Cisalpine Republic, together with a heavy war contribution. The murder of GeneralDuphot of the French embassy in December was avenged by Berthier marching on Rome and taking possession of the castle of St Angelo. Pins was called on to renounce his measures, and was deposed. His temporal and ecclesiastical powers were declared forfeited, February 20, and carried to Siena, and afterwards to the celebrated Certosa or Carthusian monastery of Florence. On the threatened advance of the Austro-Russian army in the following year he retired to Siena, and was succeeded by Prince Valence on the throne, where, worn out by age and grief, he died, August 28, 1790.

Pius VII., originally Gregorio Luigi Barnaba Chiaromonti, was born at Cesena, 14th August 1742. He entered the Benedictine order at an early age, taught philosophy and theology at Parma and at Rome, became Bishop of Tivoli, and on being created cardinal was translated to the see of Imola. After the death of Pius VI. Cardinal Chiaromonti was chosen his successor (March 14, 1800). Rome, which up to this time had been occupied by the French, was now restored to the papal authority, and in the July of that year Pius VII. entered into his capital; while next year the French troops were definitively withdrawn from the papal territory. He immediately failed to get any modification of the articles, and not six months after his return to Rome the troops of Napoleon seized Ancena, and finally in February 1806 General Moliis entered Rome, and took possession of the castle of St Angelo. Ere long a neore was imposed, which was annexed to the province of Fermo, Urbino, and Macerata to the kingdom of Italy. The usurpation was consummated (May 17, 1809) by a decree annexing Rome and all the remaining papal territory to the French empire. The pope on June 10 retaliated with a bull of excommunication directed against the robbers of the holy sea, yet without formally naming Napoleon. The unhappy pope was next removed to Grenoble, then to Savona, and finally to Fontainebleau. There he was forced into signing a new concordat, recognising the annexation of the Roman states to the empire (January 25, 1813). The fall of Napoleon allowed him to return, and on May 24, 1814 he re-entered Rome. The Congress of Vienna formally restored to him his territory, and the remainder of his reign was devoted, under the direction of Cardinal Consalvi, to the reorganisation of internal administration. Brigandage was sternly suppressed, as well as secret societies, especially that of the Carbonari; while the Jesuits were restored, and concordate concluded with Naples, Prussia, Wurttemberg, and other Catholic states.

Throughout his life Pins VII. was a model of gentleness, simplicity, benevolence, and Christian charity. He died August 20, 1823, after having broken his thigh through a fall.

Pius IX., Giovanni Maria Mastai Ferretti, occupant of the papal chair during one of the most eventful periods in the history of the papacy, was the fourth son of Count Jerome Mastai Ferretti, and was born at Sinigaglia, May 13, 1792. His epileptic attacks rendered him unfit for the Noble Guard, wherupon he turned to the study of theology, and was admitted to the seminarium, in December 1818. For five years he presided over the orphanage of Tata Giovanni, next accompanied the Apostolic delegate Monsignor Muzi to Chili. In 1825 he returned to Rome, was made canon of St. Maria in Trastevere, and was successively, March 14, 1827, a great hospital for destitute children. In 1827 he was made Archbishop of Spoleto by Leo XIII., and transferred to Imola by Gregory XVI. in 1832. In 1840 he became a cardinal, and on the death of Gregory XVI. in 1846 was elected at acclamation to succeed him. He was the leader of the reforming party, and twelve hours after his election Cardinal Garscik, Archbishop of Milan, reached Rome with instructions from Austria to
veto his election. He took the name of Pius IX., and entered at once on a course of reforms, by which he hoped to establish the papal government on a popular but yet firm basis. His first step was to grant an amnesty to all prisoners and exiles for political offences. He next removed most of the disabilities of the Jews, and made Rome a centre of a united railway system. In 1848 he projected a Consulta or council of state, and in March 1848 published his Statuto Fondamentale, a complete scheme for the temporal government of the papal states by means of two chambers, one nominated by the pope, the other (with the power of veto) elected by the people. At first the new pope was the idol of the populace. Mazzini hailed the new policy with enthusiasm, and Carlyle declared that 'the old chimera was rejuvenised!' But the revolutionary fever of 1848 spread too fast for a reforming pope, and the refusal to make war upon the Austrians finally forfeited the affection of the Romans. On November 15, 1848, his first minister, Count Rossi, was murdered in broad daylight, and two days later a threatening mob assembled in the square of the Quirinal. On the 24th the pope escaped to Gaeta, a Neapolitan seaport near the Bay of Naples. A rumour was proclaimed in Rome, the provisional heads of which proceeded with great moderation and wisdom to a complete and radical remodelling of the civil government of the state. Pius from his exile addressed a remonstrance to the various sovereigns. In April 1849 a French invasion of Italy had been sent to crush the revolution. On July 2 General Oudinot took Rome, after a siege of thirty days. The papal government was re-established, but Pius himself did not return until April 12, 1850. From this time his government, swayed by Antonelli, was the oracle of the Catholic church. The pontiff refused to proclaim the second amnesty. The war for the unification of Italy was ended in December, and a considerable part of the papal territory southward in the direction of Rome was annexed to the kingdom of Italy, but Pius persistently refused to cede any portion or to enter into any compromise.

In his ecclesiastical policy he was incessantly active, henceforward closely related with the Jesuits, and ever uncompromising in his ultramontanism, and to a large extent he proceeded to promulgate dogmatic definitions about problems that had been long unsettled by the wisdom of the ages. He re-established the hierarchy in England, he sanctioned the establishment in Ireland of a Catholic university, and condemned the principles upon which the Queen's Colleges in that country were constituted. He concluded with Austria a concordat much more favourable to church authority than the existing ecclesiastical laws had permitted. By the bull 'Ineffabilis Deus' (8th December 1854) he decreed as a doctrine of the faith the infallibility of the Pope, with the assistance of Virgin Mary; his famous encyclical 'Quanta Cura,' and the Syllabus, or list of prevalent errors especially to be reprobated, appeared in December 1864. But the most important event of his pontificate was the convocation of the Vatican Council, at which bishops from all parts of the Catholic world assembled in December 1869. It was adjourned in July 1870, after it had proclaimed the celebrated decree of the Infallibility (q. v.) of the Pope, when on a subject of faith or morals he issues a decree ex cathedra to the universal church. For the last ten years the pope's temporal dominions have been in a continual state of war, having been invaded by French bayonets, and on the withdrawal of the garrison at the outbreak of the war with Germany the soldiers of Victor Emmanuel crossed the frontier, and, after the short delay of a feeble and half-hearted defence, entered the city amid the acclamations of the populace, and so terminated the temporal power of the pope. The result of the plebiscite on October 2 was 40,805 for, and but 46 against, union with Italy, and for the rest of his days the pope lived a voluntary prisoner within the Vatican, having the mortification to see his capital become the centre of a united kingdom. In 1855 he purchased the island of Gorgona, and lived in the Quirinal with the affections of all his subjects. He renewed with all solemnity his oft-repeated protest, and refused the pension of 210,000 voted him by the national parliament. His loss was in some measure compensated by the renewal, as a result of his excommunication, of the abdication of the tribute of Peter's-pence (q. v.). In June 1871 his reign reached the unparalleled duration of twenty-five years, and on June 3, 1877, he celebrated the jubilee of his episcopal consecration. He died a month after Victor Emmanuel (to whom he sent the papal benediction), on 8th February 1878.

Pizarro, Francisco, the conqueror of Peru, was the illegitimate son of a colonel of infantry named Gonzalo Pizarro, and was born at Trujillo in Estremadura, it is believed about 1470 or 1475. He received no education, and was not even taught to read and write, but entered the military service at the age of thirty, under Don Alvaro de Bazan, 'Great Captain' (Conde de Cordova) in Italy. In 1509 we find him at Darien in the expedition of Alonzo de Ojeda. He also served under Vasco Nuñez de Balboa when he crossed the isthmus and discovered the South Sea, led an expedition as far as Rio de la Santa, crossed the isthmus on the Pacific coast, and eventually became a citizen of Panama. In 1522 Don Pascual de Andagoya also reached Biron, and there collected information respecting the great empire of the Incas. Returning to Panama to prosecute the discoveries he became so ill that he was induced by the governor to hand over the enterprise to three partners, Francisco Pizarro, another old soldier named Diego de Almagro (q. v.), and a wealthy ecclesiastic named Hernando Luque. Pizarro was to lead the expedition, Almagro was to keep open communications with the Spaniards, and promised to contribute funds. Their first attempt was a failure, but in 1526 Pizarro and Almagro sailed in two vessels, with Bartolomé Ruiz, a very expert and gallant sailor, as pilot. Pizarro landed his men, Almagro returned to Panama for supplies, and Ruiz made a voyage to the southward, being the first to pass beyond the equator to cross the equator in the Pacific Ocean. Almagro returned, and the expedition proceeded southwards. But they were not yet strong enough to form any settlement, and eventually Almagro was sent back for reinforcements, while Pizarro and part of the force remained far as Biron, having crossed the equator in 1° 57' N., called Gallo. The arrangement caused much discontent. The men complained that they were being left to starve. The governor of Panama refused to give any further contribution to an enterprise which seemed doomed to failure, and two vessels, under Pedro Tafur, were sent to bring the people back from Gallo. Pizarro refused to return. Drawing a line along the sand, he called upon those who remained resolute to achieve success in spite of all difficulties to come over to his side. Thirteen men crossed the line. The natives welcomed Pizarro and his devoted little band removed to another island, called Gorgona, where there was more game and better water. For a long time the governor of Panama refused to allow any help to be sent. At last Ruiz was allowed to sail with one small vessel. He reached Gorgona, and Pizarro embarked, full of
PIZARRO

211

hope. Sailing southward they reached the Peruvian port of Tumbes, and collected full information respecting the empire of the Incas. Returning to Panamá, Pizarro proceeded to Spain to apply for authority to undertake the conquest of Peru. The capitulation between Spain and Peru depended upon the marriage of his sister, Juana, and Pizarro was signed on 26th July 1529. Pizarro was made adelantado and captain-general, while Almagro received the title of marshall. Pizarro took back with him his four brothers, Hernando, Juan, Gonzalo, and Joaquin Martin de Almagro. He sailed from San Lucar on 19th January 1530, and from Panamá on 28th December 1531, with three vessels carrying 183 men and 37 horses. Almagro was to follow with reinforcements. Landing at Tumbes, the Spaniards commenced the march inland in May 1532, and on 15th November entered the city of Cajamarca. The Inca Atahualpa, after defeating his brother and ending a long civil war, was in the neighbourhood, on his way to Cuzco, the capital of the empire. Pizarro captured the native sovereign by treachery, and after extorting an enormous ransom, amounting to 4,693,570 ducats (£3,500,000 of our money), treacherously put him to death on 29th August 1533. The royal share of the treasure was sent to Spain, with tidings of the conquest. Pizarro then marched to Cuzco, and set up the Inca Martín as a nominal sovereign. On 6th January 1533 Pizarro founded the city of Lima, as the capital of his new government. He was created a marquis by the Emperor Charles V., while Almagro was empowered to occupy territory for 260 leagues from the southern boundary of his government. But the southern boundary was not fixed. Almagro declared that Cuzco was within his grant, but was induced to forego his claim, and to undertake the conquest of Chili. The marquis was busy founding cities on the coast, while his brothers were at Cuzco, when a great insurrection of the Indians broke out. Both Cuzco and Lima were closely besieged, and Juan Pizarro was killed. For many months the Spaniards were in great danger, but in the spring of 1537 Almagro returned from Chili, raised the siege of Cuzco, and took possession of the last of the Inca's lands. The Marquis Pizarro had no intention of allowing his rival to retain Cuzco. Too old to take the field himself, he entrusted the command of his forces to his brothers, who defeated Almagro on 26th April 1539, and entered the city soon afterwards. The prosperity of his followers was confiscated. Pizarro remained at Lima, consolidating his power, and despatching various expeditions for discovery and conquest. But Almagro's followers were driven to desperation; they were called in derision 'men of Chili,' and the marquis treated them with contemptuous indifference. One of them, named Juan de Rada, matured a conspiracy for the assassination of the governor. The conspirators attacked his house during the mid-day meal, and murdered the old commander between the first and second course on 20th June 1541. The body of Pizarro was buried in the cathedral by stealth and at night. Francisco Pizarro is one of the most prominent figures in the history of Spanish conquest in the New World. His reputation rests on the determination of a man of inflexible constancy of purpose, equal in the infinite resource. His followers were devoted to his service, and some of his friendships endured until death. The indelible stain on his character is the treacherous execution of the Inca Atahualpa. All the capital punishment he gave to the greatest of his position, and proved himself to be an able and far-seeing administrator. Falling by the hands of assassins, he was defended by devoted friends, and died as bravely as he had lived. Pizarro was never married. By the Inca princess, Inez Huayllas Nusta, a sister of Atahualpa, he had two children—Gonzalo, who died young, and Francisca, who went to Spain with her step-father, Don Francisco Anupuerco, a knight who married Inez after the assassination of the Grand Inca. His uncle Hernando Pizarro was created a marquis at Cuzco, and by him had three sons and a daughter. Hernando, for having beheaded the Marshal Almagro at Cuzco, was imprisoned in the castle of Medina del Campo, from which he was set at liberty, when he remained until 1556. He married his niece during his imprisonment, which could not have been very rigorous. He died at Trujillo, the original home of himself and his brothers, in 1578.

GONZALO PIZARRO, brother of the Marquis Francisco Pizarro, served with his father in Italy when a boy. He accompanied his brother Francisco in the conquest of Peru, and did very good service when the Indians besieged Cuzco, and in the conquest of Chacras. In 1539 Gonzalo Pizarro undertook an expedition to the so-called Land of Cinnamon, the forest-covered region to the eastward of Quito. He left that city with 350 Spaniards and 4000 Indians on Christmas Day, and the hardships and sufferings endured by Gonzalo and his companions have seldom been equalled. Descending the rivers Coca and Napo, Gonzalo enticed the command of a small vessel from the lawful owner, and gave it to one of his lieutenants, who was to go in advance and seek for supplies. But Orellana deserted his starving comrades, discovered the whole course of the river Amazon, and returned to Spain. Out of the 350 Spaniards that left Quito 50 deserted with Orellana, 210 died of hunger and disease, and the miserable remnant returned to Quito with their intrepid leader in June 1542.

When Gonzalo Pizarro heard of the assassination of his brother the marquis he retired to his estates in Chacras. In 1544 the new viceroy, Blas Nuñez Vela, arrived in Peru to enforce the 'New Laws.' The Spaniards were dismayed, and entreated Gonzalo to leave his retirement and protect their interests. He consented, chose an old veteran named Francisco de Carabjal as his lieutenant, and assembled a force of 400 men. Pizarro was killed, and Gonzalo entered Lima in triumph on the 28th of October 1544 at the head of 1200 Spaniards, and several thousand Indians dragging the artillery. He was declared governor of Peru. Blasco Nuñez Vela died while he was at Lima, and Gonzalo was made viceroy and governor general of Peru. He was called Carabjal, and defeated and killed in the battle of Arica on January 18, 1546. Gonzalo Pizarro was undisputed master of Peru. Carabjal retired to Chacras to work the silver-mines.

When news of this revolt reached Spain the licentiate Pedro de la Casca, an astute and very able ecclesiastic, was appointed to proceed to Peru as president of an 'Audencia,' or court of five judges, and to restore order. He sailed in May 1546, and arrived at Panamá in August, where he gained possession of Pizarro's fleet by a combination of means. He arrived at Lima on 25th June 1547. Gonzalo Pizarro, desiring of being able to make head against the president, determined to retreat into Chili. But there was a force, under an officer named Diego Centeno, hanging in the wings of his host, and determined to do it first. Centeno was utterly defeated in the battle of Huarina, near the banks of Lake Titicaca, and the doomed Pizarro was so elated at the victory that he abandoned all idea of retiring into Chili. He advanced to Cuzco, and the President Casca approached him by leisurly marches, encamping on the plain of Saquishana, near Cuzco, in April 1548. On the 9th Pizarro and Carabjal marched out of Cuzco, and both sides made ready for battle. But soon there were symptoms of desertion on
Pizzacato. a phrase used in music for the violin or violoncello, to denote that there the strings are to be twitched with the fingers in the manner of a harp or guitar.

Placebo (Lat., 'I will please'), in the Roman Catholic service of vows for the dead the name of the first antiphon, which begins with the word. In medicine it is an epithet applied to a remedy intended to humour or gratify a patient rather than to exercise any curative effect.

Place-names. See Names.

Placenta, or After-birth, the structure which unites the unborn mammal to the womb of its mother and establishes a nutritive connection between them. It is a peculiar organ of transitory nature, and is a part of the maternal surface, and is not developed in Ornithorhynchus and Echidna, which lay eggs, nor is it more than incipient in the Marsupials, which bring forth their young after a short gestation. In all other mammals it occurs in various forms, partly embryonic in its origin, partly maternal, always active, and always a double type, or a sponge, by means of which the blood of the mother nourishes and purifies that of her unborn young. Vague prophecies of it occur in two cartilaginous fishes and in two lizards, in which there is a connection between the yolk-sac of the embryo and the wall of the ovipore.

In the hedgehog, which is a conveniently central type of mammal, the connection between embryo and mother has the following history. (a) The outer wall of the embryonic sac is moored to the wall of the mother by small cellular outgrowths, known as the preliminary 'villi,' and minute cavities between these are bathed by the blood of the mother. (b) The growing embryo becomes ensheathed by the double folds of the Amnion, the inner parts of which form the 'amnion proper,' while the outer form the 'extra-embryonic wall of the embryo.' Part of the yolk-sac wall fuses with this sub-embryonic membrane; from the united area vascular villi grow out into the wall of the uteri, which is now much modified. Thus is formed a yolk-sac placenta, as exhibited for a time by Insectivores and Bats. But the most important union between mother and offspring is that due to the union of Allantois (q.v.) and sub-embryonic membrane. If there has been a yolk-sac placenta it dwindles before this new and more efficient union. From the united area vascular villi grow out into depressions or crypts in the uterine wall, part of which is modified into a spongy vascular tissue. In Insectivores, Bats, and Rodents the original outer wall of the embryonic sac persists between the placental vill and the maternal blood, and mediate between these by means of a capillary network. The term 'chorion' has been used in so many senses, that it seems advisable to abandon it. It is best applied to the union of sub-embryonic membrane and allantois ('true chorion'), or to the union of sub-embryonic membrane and yolk-sac ('false chorion').

The embryonic part of the placenta necessarily comes away at birth, and sometimes the vascular part of the maternal placenta is also discharged when the young is born. When this is the case, the placenta is called 'deciduate,' or better 'non-chorionic.' Of non-chorionic presentation two kinds are distinguished: Diffuse, when the villi are scattered over the surface of the embryonic sac in Manis among Edentates, in the dugong, in Cetacea, in most Ungulates except Ruminants, in Lemurs; Cotyledonal, when the villi occur in patches (in Ruminants). Of cotyledonal presentation three kinds are distinguished: Zonary, when the villi form a partial or complete girdle round the embryo, in Orycteropus and Dasyus among Edentates, in Elephants and Hyaen, in Carnivora; Discoidal, when the villi occur on a circular cake-like disc (in most Edentates, in Insectivores and Bats, in Rodents: Meta-discoidal, when the villi are at first extended, but are afterwards restricted to a disc (in Monkeys and in Man). Sir William Turner, the 'grand-master of placental research,' allot the lowest place to such diffuse forms of placenta as that of the pig, but others maintain that the discoidal type as illustrated in the Igname vora is the most primitive. In Botany 'placenta' usually means the portion of the Ovary (q.v.) which bears the ovules. See also AMNION, ALLAN- TOIS, FETUS, MAMMAL.

Placenca. See Placenta.

Placentum Regium (called also Placet, Exegetuar, Lettres Patentes) is an act or instrument executed in virtue of the privilege claimed by the government in certain kingdoms to exercise a supervision over the communications of the Roman pontiff with the clergy and people of those kingdoms, and to suspend or prevent the publication of any brief, bull, or other papal instrument which may appear to contravene the laws of the kingdom, or to compromise the religious liberties of the Christians. In England the Statute of Praemunire (q.v.) was an example of this tendency.

Placoid Fishes. an order of fishes, in the classification proposed by Agassiz, characterised by having placoid (Gr. plax, 'a flat plate') scales of hard bone, not imbricated, but placed near together in the skin. They are all Cartilaginous Fishes (q.v.). See SCALES.

Plagal. See PLAIN-SONG.

Plagioclase. See FELS Path.

Plagiostomata. See CARTILAGINOUS FISHES.

Plague, a term used in the middle ages of all fatal epidemics indiscriminately, but now restricted
to a very malignant kind of contagious fever prevailing at certain times and places epidemically, characterized by buboes, or swellings of the lymphatic glands, and sometimes, when the disease was severe, that person had started from Lower Egypt; but from this time frequent epidemics occurred in Europe, culminating in the Black Death (q.v.) in the 14th century. It continued to ravage the north and west of Europe up till the 17th century. The last outbreak in England in 1663-65 caused the 'Great Plague of London,' and spread almost all over the country (see LONDON, Vol. VI. p. 699). Since the end of the 17th century it has only twice visited western Europe; in 1707-14 it spread from Russia and Hungary as far as Sweden, Denmark, Prussia, and Bavaria; and in 1720-22 being introduced from Syria into Marseilles, it destroyed almost half the population there, and spread through Provence. During all this time its most constant seats, so far as is known, were the countries bordering the Eastern Mediterranean—Lower Egypt, Syria, Asia Minor, and Turkey in Europe. By 1800 all these it has meantime disappeared. The last cases known in Egypt occurred in 1844, and in the others in 1841. It was hoped that the disease had become extinct, but since then it has occurred more than once in Arabia, Tripoli, Persia, and Arabia; and in 1873-75, and 1876-77, in China. In 1873-75, and 1876-77, in China. In 1875 the disease occurred in India, and 1876-77, in China. It has been present in India at least since 1815, sometimes in epidemics (e.g. the 'Pati plague,' 1830-38), but most constantly in districts on the southern slopes of the Himalayas; and it is said to be always found in some parts of India. An occurrence of the disease in Hong Kong in 1894 was followed by the fearful visitation at Bombay (q.v.) and adjoining parts of India in 1896-98.

It is the most destructive of all known epidemics. Barely less than 60, sometimes 90 per cent. of those attacked died. The disease carries off half the population of a town or of a district in which it prevails, and it may completely root out whole families, so that no survivor remains. The Black Death of 1348-50 is believed to have destroyed not less than a quarter of the population of Europe. The general symptoms resemble those of other severe fevers: shivering, rise of temperature, ache in head, back, and limbs, sickness, &c. Great weakness succeeds, with mental disturbance leading to coma or delirium. Death often occurs before any characteristic symptoms are developed; but at an early stage dark spots or patches often appear on the skin, produced by subcutaneous hemorrhages (petechiae, ecchymoses), and bleeding may also take place from the various mucous membranes. Bleeding from the lungs, though rare in recent epidemics, was regarded as a characteristic symptom of the Black Death in its most virulent form. About the second or third day the most distinctive features of the disease are developed—viz., one or more buboes or glandular swellings, usually in the neck, armpits, or groins; these generally become hard and prolonged swellings. In a few cases they are absent altogether. Carbuncles do not frequently develop at a later stage of the disease. Good nursing, good nourishment, free stimulation, and early opening of the buboes are helpful. Various treatments with diaphoretic and purgative medicines have been used in the Bombay epidemic of 1896-98. There can be no doubt that it is a highly infectious disease, and that the infection may be conveyed by clothes, bedding, &c., as well as by direct contact with the sick. In all epidemics it has been observed that the unhealthy conditions produced by poverty and filth are extremely favourable to the disease, and that it has been much less prevalent and severe among those in comfortable circumstances and healthy surroundings.

See Hucker's *Epidemics of the Middle Ages* (published by the Sydenham Society, 1844); Hirsch's *Geographical and Historical Pathology* (vol. I., New Sydenham Society, 1853); and the articles BLACK DEATH, ENDEMIC, PLAGUE.

Plague is a frequent trouble of theRomney Marsh, a common flatfish in the same genus as the flounder. It usually inhabits sandy and muddy banks off the European coasts from France to Iceland. Like the flounder, it may pass off estuaries into rivers, and can even thrive in fresh-water ponds. It often lies slightly buried with its eyes exposed and watchful for prey. The food consists of molluscs, crustaceans, and worms, but especially of the first. It spawns in early spring, and is in best condition about the end of May. It was once a common belief that shrimps were the parents of place. The place is rather broader in proportion to its length. The average size is 2 to 3 pounds, but much larger specimens are often caught; the coloured side is predominantly olive-brown with orange spots, but the colour changes rapidly in precise harmony with that of the ground on which the fish rests; six blunt toes extend from the eye to the beginning of the lateral line, which has an almost straight course.

Plain. See Highlands.

Plain, a geographical term which hardly admits of precise definition. It is generally applied to extensive tracts of approximately level or undulating country, which occur at less than 1000 feet above the sea. Broad areas of similar character at higher elevations are usually termed Tablelands (q.v.) or Plateaus. This is the general rule, but when the surface of a plain slopes gradually upwards to heights of several thousand feet, the whole tract is still called a plain. As an example may be cited the great plains east of the Rocky Mountains, which fall imperceptibly away towards the east from an elevation of 6000 feet or so. Among the most characteristic plains are the wheat lands of the greater rivers. But the term is extended to such low-lying regions as the Netherlands, the Midlands of England, the middle Europe, &c.—regions which have no great elevation and present a gentle undulating surface, interrupted now and again by isolated hills, and lines of cliffs and escarpments. From the same point of view the whole interior of North America lying between the Rocky Mountains in the west and the Alleghany and White Mountains in the east, and extending from the Gulf of Mexico to the shores of the Arctic Ocean, may be called a plain. So likewise more than half of Europe is a plain that is continued into Asia, and extends through the vast regions of that continent. Plains necessarily differ much in appearance according to the nature of soil and climate, from the dreary, sandy wastes of North Africa to the luxuriant fertility of the South American savannas, and to the wide rectangular level ground in each of the great continents have acquired various names, such as the Steppes and Tundras of eastern Europe and Asia, the Deserts of Arabia and Africa, the Savannas and Prairies of North America, and the Llanos, Pampos, and Serras of South America.

Plainfield, a city of New Jersey, on Green Brook, 24 miles by rail WSW. of New York, many of whose business men have their homes here.
Clothing, hats, and machinery are manufactured. Plo. (1890) 11,267; (1900) 15,369.

Plain-song. Plain-Chant, Gregorian Giant, or Gregorian Music, is the music used in the Christian church of the West from the earliest times, still in use in all Roman Catholic churches, and extensively revived since the rise of the High Church party in the English Church. Many good musicians, however, consider its interest as antiquarian rather than musical. Its distinguishing points are (1) its recitative-like character, as opposed to what was styled musica mensurata—i.e. barred music, with a marked and regular rhythm, which was the essential point of ancient Greek music, and more or less of nearly all modern music; (2) the modes, or scales, in which it is written, which are more numerous and varied than the modern major and minor; and (3) its being (originally) sung in unison, though much of it is susceptible of treatment in harmony, and is now frequently so heard. It used to be stated also that the notes in it were all of equal length, but this view is now generally repudiated and condemned. It embraces music for all parts of the Roman services, from the Accents (nearly in monotonous) proper to the various readings to the more elaborate melodies of the antiphons and hymns, and the various parts of the mass. The best known and most ancient of all is the music of the eight Tones sung to the Psalms, commonly called the Gregorian Tones. As to the origin of these many different views prevail, some ascribing them to a Greek, some to a Hebrew source, others to the early Christians; there seems some probability, though there is no direct evidence, that they were actually derived from the music of the temple service. As at first plain-song was handed down orally only, and the early systems of notation were very defective, it is impossible to determine how far it may have been corrupted. It was first reduced to system by St. Ambrose (died 397), but much more extensively by St. Gregory the Great, towards the end of the 6th century. There have of course been large additions since. How he noted the music is uncertain; the early notation and rules of plain-song were so complicated that it is said ten years' study were necessary to acquire a mastery of them. Local varieties of the proper modes gradually sprang up, almost every diocese having an office-book peculiar to itself—e.g. the antiphonary and gradual of Sarum, said to be one of the purest. The earliest known existing record of plain-song is the Antiphonarium, or rather Gradual, in the library of the monastery of St. Gall in Switzerland, probably of the 8th or 10th century. Various directories have been published, notably that begun by Palestrina and finished by Guidetti; the latest, issued under sanction of the pope, is the great series published at Ratisbon by Pustet, beginning in 1871 with the Gradual. The music is still always printed in the old square notes on a stave of four lines. At the Reformation the Gregorian music was adapted to the new vernacular services of the English Church by John Marbeck, who published in 1530 The Book of Common Prayer noted; and his arrangement is still in use in cathedral services. Anglican Chants (q.v.) are modelled on the Gregorian psalm tones.

The modes, or scales, of plain-song require some explanation. Their variety has been acknowledged by first-rate authority as affording greater resource of expression than our major and minor modes; and music has been written in them by great modern composers—e.g. the 'Hymn in the Lydian Mode' in Beethoven's Quartet, op. 132. They

were derived from, though it is not certain that they were identical with, the Greek diatonic scales, after which they have been named. The principle of their formation is that each of the seven natural notes of the diatonic scale forms the keynote, or 'final' of a mode, which embraced that note and the five notes below it, carried down an octave, and no flats or sharps are found except an occasional B flat.) This would give us seven modes; but to each of these is attached another, in which the melody lies between the keynote and its octave, but in the other between the fourth below and the fifth above the keynote. But while the mode Dorian (authentic) embraces the notes from D of the bass stave to the D above, and has its keynote on D; the 2d or Hypo-dorian (plagal) has the same keynote, but its compass is from the A below to the A above it; the 3d or Phrygian (authentic) and its corresponding plagal mode, the 4th or Hypo-phrygian, is to be distinguished from them by its keynote on the E of the third space of the bass stave; the 5th or Lydian and 6th or Hypo-lydian have F for final; the 7th or Mixo-lydian and 8th or Hypo-mixo-lydian have G; the 9th or Æolian and 10th or Hypo-æolian end on A; and from these are derived all the other modes. The other modes are numbered variously as 11th and 12th, or 13th and 14th, according to the rejection or inclusion of the two preceding. The Ionian is the mode numbered 1, and the arrangement of the modes was said to have been confined to the 1st, 3d, 5th, and 7th modes (authentic); while the relative plagal modes, 2d, 4th, 6th, and 8th, were added by St. Gregory. In these are written the correspondingly relative modes, in the psalm tones of St. Gregory, with the Gregorian Tone, used only for the psalm In exitu Israel, in the 9th mode. The other modes were finally added in the 8th century under Charlemagne. Each mode has its reciting note, or Dominant—not to be confounded with the modern term in harmony.

Various specimens of plain-song hymn melodies will be found in Hymns Ancient and Modern—e.g. No. 14, the vesper hymn of St. Ambrose, 'O Lux beata Trinitas'; and No. 96, the hymn of Fortunatus, 'Vexilla Regis prodeunt,' which may be studied in a different treatment by Coussin in the "March to Calvary." See his Redemotio.

See the Rev. Thomas Helmoc's Manual, Brief Directory, and Primer of Plain-song; various articles by Mr. W. S. Bockstoce in Grove's Dictionary of Music; and the Magister Choralis, by Rev. W. K. Haberl (trans. by Dr. S. P. Bhaskar). The earliest list of the official Roman Directorium was printed in 1574, also at Ratisbon, by Pustet. See also the article HARMONY.

Planarian. a term practically co-extensive with trematode, applicable to the members of the lowest class (Turbellaria) of worm-like animals. They live in fresh and salt water and sometimes in damp earth. They are unjointed 'worms' with a ciliated skin; the food-canal is often branched, but has no posterior opening; from the simple brain two lateral nerves extend backwards; the body-cavity is undeveloped; there are no respiratory or eirenutary organs; the excretory system consists of branching tubes ending in ciliated cells; all other organs are simple; the life-history and the natural history, simplicity is well illustrated by the fact that some multiply by dividing into two, while a fragment of others may re-grow the whole. In Microstoma linfare a temporary chain of eight or sixteen individuals is sometimes formed by budding. In diet they are carnivorous, but a few are parásites —suggesting the next class of Trematodes. As illustrative genera we may note Planaria, in fresh water; Vortex and Convoluta, with green species (the colour being probably due to partner Algae); Gunda, with hints of segmentation; Microstoma and Stenostoma, the two subclass genera; Graillla and Anoplophilium, parasitic; Bipalium and Geodesmus, on land; Cephaloplane and Ctenoplana, in some ways suggestive of the Colerentor Ctenophora.

Planche, JAMES ROBINSON, playwright, archeologist, and herald, was born in London, 27th February 1796, the son of a watchmaker of Huguenot descent. His earliest dramatic exploit was produced at Drury Lane Theatre in 1818, and others soon followed. In 1823 he designed for Charles Kemble the dresses and appointments for the play of King John, and afterwards for other Shakespearean productions. In 1824 he wrote English words for Berlioz's Damnation of Faust, which was produced at the Olympic, nearly 200 dramatic pieces came from his pen—the most adaptations, but a large number original dramas (e.g. Charles XII) and entertainments. Of the five five numbers were published in 1830. In 1843 he helped to found the British Archaeological Association, and for many years he contributed valuable papers to the proceedings of the Society of Antiquaries. In 1854 he was made Ronce Croix Pursuivant, and in 1866 Somerset Herald; in 1872 he received a civil list pension of £250 a year. He died 29th May 1880.

Among Planche's works, besides two histories of British costumes and a Cyclopaedia of Costumes, are his Introduction to Heraldry (18th ed. 1860); Regal Records, or a Chronicle of the Royal Arms of England (1838); The Pursuivant of Arms (3d ed. 1874); and The Conqueror and his Companions (2 vols. 1874). See his Recollections and Reflections (2 vols. 1872).

Planche, a thin heart-shaped piece of wood mounted on three props, two of which are furnished with castors, and one is a pencil which may be made to trace characters on a sheet of paper by resting the fingers upon the instrument, and thus almost insensibly steering it in any direction required. Its use is as a supposed medium for spiritualistic communication; and it is one of the more sensitive modes for the transmission of information. It is used in the proceedings of the Psychical Society (1888, &c.).

Plane (Platamun), the sole genus of trees of the natural order Platanaceae. The species of plane are few; natives of temperate climates in the northern hemisphere, but also found, though in small palmate leaves and smooth whitish bark, which annually scales off in large pieces.—The Oriental Plane (P. orientalis), a native of Greece and the East, was planted by the Greeks and the Romans as an ornamental tree, and was cultivated for centuries the yhouth of Greece assembled under its shade in the groves of Academus to receive lessons in philosophy. The plane is still planted for shade...
and ornament in the south of Europe. Many fine trees exist in England, but they were at one time much more numerous, great part having died in the end of the 18th century. The spring frosts and the insufficiency of the summer for the proper ripening of the wood render Scotland less suitable for its cultivation, yet there is a tree at Gordon Castle 66 feet high. No tree better endures the atmosphere of a large city, and there are no finer trees within the precincts of London than its plane-trees. Noble specimens are to be seen in Hyde Park and Russell Square, in London, and the avenue of the Thames Embankment is formed with this tree. In the East the plane attains an immense size. One tree in the meadow of Boyndiere, on the banks of the Bosphorus, is 141 feet in circumference at the base, extends its branches 45 feet from the trunk, and is believed to be more than 2000 years old. The wood of the plane, when young, is yellowish white; when old it is brownish, fine grained, takes a high polish, and is esteemed for cabinet-making. A rich alluvial soil and the vicinity of water are most suitable to this tree. The North American Plane, or Buttonwood (P. occidentalis), is a very similar tree. It is the largest deciduous tree of the United States, and abounds on the banks of the great rivers of the middle states. Its timber is not very valuable, and is very liable to decay. A tree of this species on the bank of the Thames, in Chelsea Hospital gardens, is 115 feet high, with a trunk 5 feet in diameter.—The name plane-tree is commonly given in Scotland to what in England is known as the Sycamore (Acer pseudes), which resembles the true planes in its foliage, but is neither a plane nor a true sycamore, being really the Greater Maple. See MAPLE.

**Planetarium.** See Orrery.

**Planetoids, or Asteroids, are now usually known as Minor Planets.** See PLANETS.

**Planets** (Gr. πλανήται, 'a wanderer') are those heavenly bodies (including the earth) which belong to our solar system, and revolve in elliptic orbits round the sun. They are often denominated primary planets, to distinguish them from the satellites or satellites, which are called secondary planets. The name planet is of considerable antiquity, and was applied to these dependent planets to distinguish them from the myriad of luminous bodies which stud the sky, and which present to the naked eye no indication of change or revolution (see STARS). The planets at present known are, in the order of their distance from the sun, Mercury, Venus, the Earth, Mars, the Planetoids (q.v.), Jupiter, Saturn, Uranus, and Neptune. Six of these, Mercury, Venus, the Earth (which was not, however, the first to be reckoned a planet), Mars, Jupiter, and Saturn, were known to the ancients; Uranus was discovered by Sir William Herschel (q.v.) in 1781; and Neptune, after having its position and elements determined theoretically by Leverrier and Adams, was discovered by Professor Challis and Dr. Galle in 1846. (The Planetoids, of which some 300 are now known, have all been discovered since January 1, 1801. Six of the planets, the Earth, Mars, Jupiter, Saturn, Uranus, and Neptune, are attended by one or more satellites; Uranus (generally), Neptune, almost all the Planetoids, and all the satellites except the Moon are invisible to the naked eye. The visible planets can be at once distinguished from the fixed stars by their clear steady light, while the latter have a sparkling or twinkling appearance. The planets, as observed from the Earth, move sometimes from west to east, sometimes from east to west, and for some time remain stationary at the point where progression ends and retrogression commences. This irregularity in their movements was very puzzling to the ancient astronomers, who invented various hypotheses to account for it. See PTOLEMAIC SYSTEM, by The system of Copernicus, by assuming the sun, and not the earth, as the centre of the system, explained with admirable simplicity what seemed before a maze of confusion.

The planetary orbits differ considerably in their degrees of eccentricity, the Planetoids, Mars, and Mercury being most, and the larger planets least eccentric. No two planets move exactly in the same plane, though, as a general rule, the planes of the larger planets nearly coincide with that of the ecliptic. The latter are consequently always to be found within a small strip of the heavens extending on both sides of the ecliptic; while the others have a far wider range, Pallas, one of them, having the angular elevation of its orbit no less than 34° 42' above the ecliptic. According to Kepler's Laws (q.v.), the nearer a planet is to the sun the shorter is the time of its revolution. The arrangement of the planets in the solar system bear no known relation to their relative size or weight, for though Mercury, Venus, and the Earth follow the same order in size and distance from the sun, yet Mars, which is farther from the sun, is much less than the earth or Venus at their respective distances, which are still farther off, are the least of all. Jupiter, which is next in order, is by far the largest,
being about $\frac{1}{2}$ times as large as all the others together; and, as we proceed farther outwards, we find Saturn less than Jupiter, and Uranus than Saturn, though Neptune, the remotest, is somewhat larger than Uranus.

With reference to their distance from the sun, as compared with that of the Earth, the planets are divided into superior and inferior; Mercury and Venus are consequently the only 'inferior' planets, all the others being 'superior.' The inferior planets must always be on the same side of the Earth as the sun is, and can never be above the horizon of any place (not in a very high latitude) at midnight; they are always invisible at their superior and inferior conjunctions, except when, at the latter, a transit (see SUN) takes place. The superior planets are likewise invisible at conjunction, but when in opposition they are seen with the greatest distinctness, being then due south at midnight. The time which elapses from one conjunction to its corresponding conjunction is called the synodic period of a planet, and in the case of the inferior planets must always be greater than the true period of revolution.

![Diagram showing the comparative sizes of Sun and Planets](image)

**Mercury**, the planet which is nearest the sun, is also, with the exception of the Planetoids, the smallest (being only three times the bulk of the moon), and performs its revolution round the sun in the shortest time. Its greatest elongation is never more than 27°-45°, and consequently it is never above the horizon more than two hours after sunset, or the same time before sunrise; on this account, and from its small apparent size (5° to 13°), it is seldom distinctly observable by the naked eye. It shines with a peculiarly vivid white or rose-coloured light, and exhibits no spots. Its year (or sidereal period of revolution round the sun) is 87-360 days.

**Venus**, the next in order of distance and period, is to us the most brilliant of all the planets. Its orbit is more nearly a circle than any of the others, and when at its inferior conjunction it approaches nearer to the Earth than any other planet. Its apparent angular dimensions thence vary from 10° at the superior to 60° at the inferior conjunction. Its greatest elongation varies from 45° to 47° 12', and therefore it can never be above the horizon for much more than three hours after sunset, or the same time before sunrise. While moving from the inferior to the superior conjunction Venus is a morning star, and during the other half of its synodic period an evening star. When this planet is at an elongation of 40° its brilliancy is greatest, far surpassing that of the other planets, and rendering a minute examination through the telescope impossible. At this period it sometimes becomes visible in the daytime, and after sunset is so bright as to throw a distinct shadow; observers have repeatedly attempted to ascertain the nature and characteristics of its surface, but its brightness so dazzles the eyes as to render the correctness of their observations at best doubtful. From the changes in the position of dusky patches on its surface, which have been frequently noticed, it is concluded that it revolves on its axis, and that its equator is inclined to the plane of its orbit at an angle of 75°; but many astronomers doubt these conclusions. Its year is 224-7 days. Professor Schiaparelli has shown reason for believing that both Mercury and Venus always present the same face to the sun. Both Venus and Mercury necessarily exhibit phases like the moon. For transits of Venus, see Sun.

The Earth, the next planet in order, will be found under its own name; it has a single satellite, the Moon (q.v.). Its year is 365-256 days.

**Mars**, the first of the superior planets, is much inferior in size to the two previous, its volume being about 4th of the Earth's, and, after Mercury, its orbit is much more eccentric than those of the other planets. When it is nearest to the Earth (i.e. in opposition) its apparent angular diameter is 30°; when farthest from it (i.e. in conjunction), not more than 4°. Mars revolves on its axis (which is inclined at an angle of 25° 27') in 24 hours 37 minutes, and its year is 687 days long. In 1877, Hall of Washington discovered that it had two satellites, now named Phobos and Deimos. It shines with a fiery red light, and is a brilliant object in the heavens at midnight when near opposition; when seen through the telescope its surface appears to be covered with irregular blotches, some of them of a reddish, others of a greenish colour, while at each pole is a spot of dazzling white. The red spots are surrised to be land; the green, water; but the markings on Mars appear to have changed considerably since they were first observed. The white spots at the poles are with some reason supposed to be snow, since they decrease when most exposed to the sun, and increase under the contrary circumstances. The Phases (q.v.) of Mars range between full, half, full (in conjunction, if visible), and half.

**The Planetoids.**—After Mars in order come the Planetoids (see below), formerly but improperly called Asteroids.

**Jupiter**, the next in order, is the largest of all the planets, its bulk being more than 1400 times that of the Earth, though, from its small density, its mass is only 300 times. After Venus it is the brightest of the planets and the largest in apparent size, its angular diameter varying from 30° to 50°.
When looked at through a telescope it is seen to be considerably flattened at the poles, owing to its rapid revolution on its own axis; and its surface is crossed in a direction parallel to its equator by three or four distinct and strongly-marked belts, and a few others of a varying nature. Spots also appear and remain for some time on its surface, by means of which its revolution on its axis has been ascertained. Separate spots give, however, slightly different periods (some even opposite one another), but a period of 9 hr. 55 min. 21 sec. is generally accurate. Jupiter has five satellites—the fifth discovered by Barnard at Lieck Observatory in 1892. The four discovered by Galileo, easily observable through an ordinary telescope, have rendered immense service in the determination of longitudes at sea, and of the motion and velocity of light. They were proved by Sir William Herschel to revolve on their own axes in the same time that they revolve round their primary. The smallest is about the same size as our Moon, the others are considerably larger. The year of Jupiter is 4332-554 days.

Saturn, next in position, is about 740 times larger in volume, though only about ninety times greater in mass, than the earth. Its apparent diameter when in opposition is 20°3', and there is a considerable flattening towards the poles. Its surface is traversed by dusky belts much less distinctly marked than those of Jupiter, owing doubtless in great part to its inferior brightness; its general colour is a dull white or yellowish, but the shaded portions, when seen distinctly, are of a glaucous colour. The most remarkable peculiarity of Saturn is its ring, or series of concentric rings, each one parallel and in the same plane with the others and with the planet’s equator. The ring become invisible. Saturn has also no less than eight satellites, seven of which revolve round it in orbits little removed from the plane of the ring, while the eighth, which is the second in size, is considerably inclined to it. They were discovered by Herschel in 1787 and 1789, four by Cassini in 1672 and 1684, one by Huygens in 1655, one by Mr. Russell in England and Professor Bond in America in 1848. The satellites are all situated outside of the ring, and the largest of them is nearly equal in size to the planet Mars. The year of Saturn is 10,759-219 days.

Uranus, the next planet in position, was discovered accidentally by the elder Herschel on 13th March 1781, and was named ‘the Georgian Sidus’ or ‘Herschel,’ but these names soon fell into disuse. It is about seventy-two times greater than the earth in volume, and thirteen times in mass; but, though so large, its distance is so much greater in proportion that astronomers have been unable to gain much information concerning it. No spots or belts have hitherto been discovered on its surface, and consequently its time of rotation and the position of its axis are unknown. It is attended by a number of satellites, but so minute do these bodies appear that astronomers hitherto have been unable to agree as to their exact number; Sir William Herschel believed sixteen of them. One of the astronomers believe in the existence of four, five, and eight respectively. That there are at least four is beyond doubt. The year of Uranus is 30,686-920 days.

Neptune is the next and outermost member of the solar system, and, at a distance of nearly 3000 millions of miles from the centre of the system, slowly performs its revolution round the sun, accomplishing the complete circuit in about 165 solar years. It is about ninety times larger than the earth, but from its extreme remoteness is of almost inappreciable magnitude when seen through an ordinary telescope. It is most remarkable for the disturbances it occasioned by the attractive force of this planet which led Leverrier and Adams to a calculation of its size and position, on the supposition of its existence; and the directions which were given by the former to Dr. Galle of Berlin, specifying its exact position in the heavens, led that astronomer to its discovery on 23rd September 1846 (see AstroNomy). Mr. Russell of Liverpool discovered that Neptune is attended by one satellite. The satellites of Uranus and Neptune differ from the other planets, primary and secondary, in the direction of their motion, which is from east to west, and in the case of the former in planes nearly perpendicular to the ecliptic. Both Uranus and Neptune were observed long before the times of Herschel and Leverrier, but they were always supposed to be stars. Neptune is known to have been observed by Flamsteed between 1690 and 1715, and by Lalande in 1735.

In astronomical tables, almanacs, &c., the planets are for convenience denoted by symbols instead of their names, as follows: Mercury, &; Venus, F; Earth, E; Mars, D; the Planetoids, in the order of their discovery, C, O, D, &c.; Jupiter, V; Saturn, D or S; Uranus, U; Neptune, W or K; the Sun, O; the Moon, M.

MINOR PLANETS. The name given to that numerous group of very small planets which is situated in the solar system between Mars and Neptune. The first minor planet, Ceres, was discovered by Pallas in 1801, and with his success romed his brother astronomers to search for more planets. Their search was successful,

Fig. 2.—Saturn, as observed by Trouvelot with the 26-inch Washington Refractor.
PLANTAIN

Jupiter.

when England (1887) to planetoids spikes, a The 1802 and smaller detection (excepting 1846) has passed without adding to the list. The number known at the beginning of 1851 was 13, of 1861 was 62, of 1871 was 112, of 1881 was 219; in 1898 there were 430. This great success of the astronomers of our time is due to the very minute observations which the zodiacal belt has been explored, and the place and apparent size of every star of this region distinctly determined; so that the presence of a wandering body can at once be detected. Among the most successful of the discoverers of planetoids are those of Pallas of Vienna, and C. H. F. Peters (1813-90) of Hamilton College, U.S. The former, since 1872, has discovered more than 80, on one occasion as many as 5 in a week; while the latter, after 1861, discovered 48.

The magnitudes of these celestial bodies have not been determined with any certainty, that they are exceedingly small as compared even with Merenery, the least of the other planets; the diameter of the largest among them being generally believed not to exceed 450 miles, while most of the others are very much smaller than this. They are also different from one another, being from the rest of the planets in other respects; their orbits are of greater eccentricity, are inclined to the ecliptic at a greater angle, and are interlaced in a most intricate manner, crossing each other so frequently as to form a kind of network. The consequence of this is that a planetoid which is nearest the sun at one part of its orbit is, when at another part of its orbit, farther from it than are several of the others, and a mutual eclipsing of the sun at different times is of very frequent occurrence. The mean orbit of the first 231 planetoids coincides, however, within 30" with that of Jupiter. Of the planetoids of which the elements had by 1891 been satisfactorily calculated, Medusa (No. 149) has the shortest period, 1157-69 days, and Hilda (No. 153) the longest, 2960-92 days. The corresponding mean distances from the sun, expressed in parts of the earth's mean distance, are respectively 2.13275 and 3.90223. Till 1875 the extreme known in this respect were Flora and Sylvia respectively. The nearest approach to the sun is made by Phoecea (perihelion distance, 1.787). Freca recedes farthest from him (aphelion distance, 4.002). Polyhymnia's orbit has the greatest eccentricity, amounting to 0.33985; Lomnia's the least, 0.2176. Massalia's orbit makes a smaller angle—only 41° 7'—with the ecliptic than that of any other planet in the solar system, while the inclination of the orbit of Pallas is no less than 33° 42' 41". After the first two or three of these bodies had been discovered the opinion was pronounced that they were but the fragments of some large planet; and this hypothesis received corroboration from the intimate connection which was shown to subsist among them; but of late years it has fallen out of favour with astronomers, who infer that the planetoids are best accounted for by the nebular hypothesis. It has been calculated that the combined mass of all the planetoids cannot exceed one-fourth of the earth's mass.

For a Table of the periods, distances, size, density, &c. of the planets, see SOLAR SYSTEM. See also PHOTOGRAPHY, and SPECTRUM.

Planimeter, a machine for measuring areas on a plane. The best-known form is that of Professor J. Ansler-LaFfion of Schaffhausen, the theory of which will be found discussed in Williamson's Integral Calculus, and in Minchin's Uniplanar Kinematics. It consists of two rods hinged together. The extremity of the one rod is fixed, so that the free extremity of the other is able to trace out any form of curve, and only in size by the dimensions of the apparatus. The theory of the instrument depends upon the fact that, as the free end is made to trace out the boundary of any closed area, the hinged end oscillates to and fro along a curve, but traces out no area. Rigidly attached to the rod whose one end traces out the plane area is a graduated roller fixed with its axis of rotation parallel to the line joining the hinge and the tracing point. As the closed curve is being described the roller rotates because of the lateral movement of the rod; and the difference of the readings before and after the tracing has been accomplished gives a number proportional to the area that has been gone round. To Ansler-LaFfion also is due a more elaborate form of integrator capable of measuring moments of inertia of areas. It greatly facilitates the calculation of the areas of the planetoids, and curves of stability in naval designing.

Plantage, the surname of an Angvin family which in 1154 succeeded in the person of Henry II. to the throne of England on the extinction of the Norman dynasty in the male line, and reigned till 1485, when the battle of Bosworth gave the crown to the family of Tudor. The name was first adopted by Geoffrey, Count of Anjou, husband of Matilda, the daughter of Henry I., from the ledge of a sprig of broom (planta genista) which he wore in his bonnet; and Henry I. is the only king to whom Mr Freeman would allow the name. The Plantagenet kings were Henry II., Richard I., John, Henry III., Edward I.—III., Richard II., Henry IV.—VI., Edward IV.—V., and Richard III. See the separate articles on these names; also, for the great struggle between its two rival branches, the article ROSES (WARS OF THE). Miss Norgate's England under the Anglo-Saxon Kings (3 vols. 1887) is an altogether admirable history of the Plantagenet period as far as the reign of John.

Plantain. For the tropical plantain (Musa), see BANANA. The English plant so called belongs to the Plantaginaceae or Plantaginaceae, and is the natural order of exogenous plants, mostly herbaceous and without stems; the leaves being in rosettes, flat and ribbed, or taper and greater. Greater Plantain (Plantago major), fleshy; the flowers usually in spikes, and generally hemisphered; the calyx persistent; the corolla hypogynous, membranous, persistent, its limb 4-parted; the stamens four, inserted into the corolla, with
long filaments; the ovary free, of a single carpel, 1—4-celled; the cells containing one, two, or many of the seeds, and surrounded by the ovary walls.

The testa of the seeds abounds in mucilage, which is easily extracted by boiling water. There are about 120 known species, diffused over all parts of the globe, but most abundant in temperate and cold countries. The most important genus is Planainago, the species of which often receive the English name Planainago. Five of this genus are found in the United Kingdom, the chief of which are the following: the Greater Planainago, or Waybread (Planainago major), one of the most common of British plants; a perennial, with broad ovate stalked leaves, and the cylindrical spike, generally set in a spout, and clusters of flowers, broad-spreading, white, and scented. It is very widely diffused over the world. Its seeds are a favourite food of birds, and the gathering of the spikes to feed cage-birds is familiar to every one. The leaves are applied to wounds by the peasantry in many districts. They are said also to be a useful application to ulcers and indolent scrofulous tumours.

—The Rubwort Planainago, or Ribgrass (P. lanceo-
lata), is another very common British plant, forming no small part of the herbage of many meadows and pastures, and sometimes sown by farmers, but with doubtful wisdom. Its leaves are lanceolate and taper at both ends; its spikes are short, ovate or cylindrical, and placed on long angular stalks. Its seed is acceptable to cage-birds. This is the plant commonly known as ‘bullies,’ or ‘sedges,’ the striking off the heads (or spikes) of which is such a favourite amusement of children. —The mucilage of the seeds of P. isophylla and of P. psyllium is much used in India in catarrh and other complaints; and P. psyllium—called Eleavor, and its seeds Fleece— is cultivated in France for the sake of this mucilage, which is used by the natives in preference to that obtained from linseed, and is also extensively used by tallow manufacturers for stiffening their goods. The plant has a branched spreading stem, and recurved leaves.

**Plantain-eaters** (Musophagidae), a family of Pie-like birds, of African distribution, arboreal habits, and vegetarian diet. The species of Musophaga, the Indonesian, the Turaco (Turacnas) are light green with carmine wing-feathers. This occurrence of a green pigment (tuncoverdin), as distinguished from a green colour, is unique among birds, and the carmine pigment (turacin) is also interesting because it seems to be partially washed out in the rainy season.

**Plantation** See ARBOCULTURE. "His Majesty's Plantations" was a not unusual term in the 17th and 18th centuries for the British settlements in America, to which it was customary to transport offenders, political and other, till the American Revolution. See PRISONS.

**Transportation.**

**Plant-houses** are garden structures, designed for the propagation and cultivation of the plants of warmer climates than our own. Apart from the style of architecture, a plant-house must be so constructed as to admit a maximum of light to the interior; there must also be ample provision for ventilation, and means for maintaining such atmosphere as is necessary for the plants that are to be cultivated in it. Glass, wood, and iron are the materials of which plant-houses are made. Masonry is not essential in the erection of plant-houses, but it is very generally employed to give stability, durability, and architectural effect. Glazing material: the larger the amount of it that enters into the structure of a plant-house the better adapted will it be for the cultivation of plants; the means for securing the maximum of light is thereby provided, and its regulation is then under the control of the cultivator.

Under the term plant-house is included every kind of horticultural glass erection employed in the culture of flowering and ornamental plants, as distinguished from those which are devoted exclusively to the culture of fruit-trees or other plants that can be grown solely for the sake of their fruit. They are broadly divided into three classes —viz. hothouse or plant-stove, intermediate house, and greenhouse. The structure of each class may be the same in all respects except in the power of the planting apparatus. In the hothouse it must be adapted for the cultivation of one or two plants; in the intermediate house the heat is regulated irrespective of the temperature of the outer air; in the intermediate house the heat of extra-tropical and temperate countries must be provided; and in the greenhouse all that is required of the heating apparatus is the exclusion of frost or the maintenance of a minimum temperature of 40° F. Hothouses are either dry or moist, according to the class of plants to which each may be devoted; the natives of dry tropical regions and those of maritime lake and river districts severally requiring special adaptations in connection with the heating apparatus. Thus there may be tropical orchid-houses, tropical fern-houses, tropical aquatic-houses—the latter being fitted with tanks of heated water, in which Victoria regia, Nymphaeas, and other aquatic plants of the tropics are cultivated; but the more common class of stove is that in which the internal arrangements are made with the view of accommodating a large variety of plants, having considerable diversity of constitutional requirement. The intermediate house may be subdivided in the same way into the cool orchid-house, the cool fernery, &c.; but more commonly it is adapted to the wants of miscellaneous plants, and very often indeed it is used temporarily for tropical plants during their period of rest, when a lower temperature and less humidity than those of the stove are desirable. The greenhouse must be heated or heated-house, when it is heated by means of glass-cases, for the culture of Cape hens (Erica) and kindred plants, or it may be a New Holland house, if its inhabitants are chiefly composed of the interesting natives of New Zealand, Tasmania, and other temperate parts of Australasia.

The conservatory is a plant-house in which a miscellaneous collection of plants, which, having been grown elsewhere, is placed in order to display the beauty of flowers and foliage. It may be either cool or hot, according to the class of plants accommodated in it. Being usually a place of resort, or a lounge accessible from the drawing-room or some other part of a mansion, its architectural features should be in harmony with those of the building of which it forms a part; but due regard should also be had, in deciding upon architectural details, to the providing of ample light, and the means of securing perfect ventilation. The purpose of a plant-house devoted to the purpose of rearing the several classes of plants indicated in the foregoing, either by seeds, cuttings, grafting, or any other mode that may be required in particular cases. It may be heated or cool, and may or may not be heated. Some of the greenhouses are being more restricted in atmosphere. It is fitted with close glass-cases, fixed or portable, for the purpose of preventing exhaustion, by the atmosphere, of cuttings and other subjects temporarily destitute of roots. An essential feature of the conservatory is the management of the atmospheric humidity. A bed or beds filled with sand, cocoa-nut fibre, or any other clean material, in which the pots containing cuttings may be plunged at will, to prevent evaporation from their sides and fluctuations of
PLANTIGRADES PLANTS

temperature in their contents. These beds are usually provided with hot-water pipes, tanks, or flues below, for the purpose of giving bottom heat when required.

Plantigrades. See Bear, Carnivora.

Plantin, CHRISTOPHE, an eminent printer, was born at St Avertin, near Tours, in 1514, and settled as a bookseller at Antwerp in 1549; some six years later he began to print. The books that came from his office are distinguished for their accuracy and beautiful workmanship and finish. His business prospered, and he had often twenty pressmen or more in active operation at once. The most noted of all his publications is the Biblia Polyclogata (8 vols. 1569-73), which was printed under the personal superintendence of Arias Montanus, the court chaplain of Philip II. of Spain. Plantin's editions of the Bible in Latin, Hebrew, and Dutch, and editions of the Greek and Latin classics, are scarcely less celebrated. He died at Antwerp, 1st May, 1589. He had founded printing-establishments in Leyden and Paris, and these, with that in Antwerp, were carried on by the husbands of his daughters. His office in Antwerp remained in the possession of the family of John Moretus, his son-in-law, until it was bought by the city in 1576 for 1,200,000 francs; out of this was created the "Musée Plantin." (1877).

See Life by Max Rooses (in French, Antwerp, 1882); Backer and Uedens, Annales de l'Imprimerie Plantin. (Brussels, 1885); Degorge, La Maison Plantin (4th ed. Paris, 1874); and Correspondence de Plantin (edited by Rooses, Ghent, 2 vols. 1884-86).

Plant-lice. See Aphides.

Plants. It is not possible to frame a complete definition of a plant as opposed to an animal; the most obvious distinction is that a plant is fixed, while an animal moves; and though it is quite true that plants form that kingdom of nature which is called fixed, or hid-between, while the animal life is more vigorous, yet, there are many animals, such as the sea-anemone, which are fixed as a plant; and all plants are sensitive to the sun's rays, and move in response. Nor can we make a formal distinction between them in terms of the food they require, for all animals eat plants, and vice versa. But it is upon simple unorganised materials, the salts and water of the soil, and the carbonic acid and oxygen of the air, and indeed serve as the source of all food for animals, yet there are many parasitic plants which live on the juices of other living creatures. What we do know is, that it is impossible that at the bottom of the ladder of life there are innumerable living creatures which it is a mere formality to call either plants or animals. From such creatures as these it is possible that the two great kingdoms of nature have been evolved step by step in constantly diverging lines. But the diversity of nature of plant and animal life is such that they are mutually helpful to each other; plants having the means of feeding upon the carbonic acid of the air, using the carbon and gas thus formed, and animals, thus forming matter for the life of animals, who in return, by bounteering carbonic acid, help to keep the air in a fit state for plants. This mutual relation of the two kingdoms finds another expression in the aid that insects receive from plants. The insects, after feeding, will oftentimes in their search for honey they become covered with pollen, and carrying it from flower to flower secure cross-fertilisation; while it is probable that the bright colours of flowers have been to a certain extent evolved by nature to seduce the insects who visited them have exerted, by going more often to those of the brighter colour.

For the classification of plants and list of allied subjects, see BOTANY; for their life-processes, see VEGETABLE PHYSIOLOGY; see also the articles AGRICULTURE, BIOLOGY, CULTIVATED PLANTS, FIBROUS SUBSTANCES, FLOWER, GARDENING, and those on the great groups of plants—ALGAE, CONIFERS, CYCADS, Ferns, Fungi, &c.

 Movements of Plants. The movements of plants may be divided into (1) those that take place during growth, including those growths, many of which are common to all plants; and (2) those that may be seen in mature plants—these are rather the exception than the rule. The whole matter is fully treated in the article on Vegetable Physiology (q.v.); here a short and general account will be given.

Growth, in its rate and direction—the direction being really determined by the relative rate of various parts—is influenced by many factors; the effects of temperature, light, gravitation, and moisture are well understood.

Temperature. There is a certain temperature at which growth is most rapid, also a minimum and a maximum at which it ceases; these points are different for different plants.

Light. The formation of chlorophyll and therefore of starch occurs, in nearly all cases, upon light, but that light generally retards growth may be seen by the long stems of plants grown in the dark, and by the bending of plants grown in a window towards the light. In a few cases, as in the older parts of certain stems of the growing parts, this movement is rapid, so as to introduce the so-called centripetal force; the stem will grow towards the centre, that is, in the direction opposite to that of the acting force, and the root away from it, that is, in the direction of the acting force.

Gravitation.—Stems generally grow upwards and roots downwards; that this is an effect of gravitation is proved by the following experiments. Place a seedling in a horizontal position; the growing tip of the stem will turn upwards and that of the root downwards. Rotate a plant slowly in a vertical plane, so as to cause the direction of gravitation to alter constantly; the direction of the growth of the stem is horizontal while the direction of that of the root is vertical, the one moving rapidly, so as to introduce the so-called centrifugal force; the stem will grow towards the centre, that is, in the direction opposite to that of the acting force, and the root away from it, that is, in the direction of the acting force.

Moisture. Stems generally grow in the direction of the greatest moisture. This effect is a stronger one than that of gravitation, for if seeds germinate in a sieve filled with damp sawdust the roots at first grow downwards until they have grown through the sawdust out into the dry air; then the direction of growth changes, and the tips bend round and grow up again into the damp sawdust.

'Spontaneous' Movements of Growing Plants.—There are other movements of growing parts the causes of which are not well understood. Thus, the leaves of a young bud are kept close together, bent over the tip of the stem, by the more rapid growth of their under than of their upper surfaces. When the bud is older the upper surfaces of the leaves begin to grow more quickly than the under surfaces and the leaves unfurl. Such movements are spoken of as mutations. The tips of climbing stems describe a 'circumvolution' due to successive alterations in the rate of growth of the sides of the stem. It is in virtue of these movements that such plants are able to climb by twining round a support. Such movements are further complications (see VEGETABLE PHYSIOLOGY). All these movements are due to unequal growth of the parts of the plants.
The Movements of Mature Plants which we have now to describe are due to alterations in the turgidity of the cells. The existing stimuli of some of these movements is known: it may be contact, light, temperature; in other cases it is obscure, as we have found to be the case with some flowers of gourds. **Contrast.**—The leaves of the Sensible Plant (q.v.) drop when touched or shaken; the stamens of the Berberidaceae, when touched, bend down and come in contact with the stigma. The tentacles of Drosera bend over, and the leaves of Venus' Fly-trap close, when alights upon them (see INSECTIVOROUS PLANTS).

**Light and Temperature.**—Many leaves—e.g., those of Mimosa and Oxalis—move up and down with variations of light and temperature. The sleeping and waking of plants—i.e., the folding of many leaves and flowers at dusk and their opening in the morning—are familiar examples of the effect of variations in external conditions.

**Spontaneous Movements of Mature Plants.**—The leaves of some few plants—e.g., the *Hedyosmum gyrans*—rotate in the dark, while the leaves of *Myriophyllum*, *Trifolium* and *Lupinus* move similarly in the light. These movements are not seen in daylight, probably because they are obscured by the movements due to light. The movements of the leaflets of *Desmodium gyrans* are dealt with at TELEGRAPH PLANT. The plasmodia of *Myxomycetes* creep, bacteria and Diatoms move in a way not yet understood, Volvox swims by means of cilia, the zoospores of *Alga* and the antherozoids of *Mosses* and *Ferns* swim after they have been set free.

**MEDICINAL PLANTS.**—The study of plants with genuine or fancied curative properties is as old as mankind. Even animals seek such medicines, and it must be remembered that our early ancestors were much more familiarly acquainted with fruits and seeds, roots and bulbs than are their more carnivorous descendants. But, while it may be contended that ancient medical treatment was in great part a natural return to more primitive vegetarian diet, it is obvious that men would be quick to profit by a wide and often costly experience of plants with special properties, poisonous and emetic, tonic and narcotic, excitant and sedative. While botanical science is partly responsible for the concentration of its energies on a primitive matter medica, thus, in the writings of Hippocrates (460-377 B.C.) and those to which his name is attached 236 medicinal plants are recorded; the list swells in the works of Aristotle (387-322 B.C.) and Theophrastus (371-286 B.C.), while the 'Materia Medica' of Dioscorides (born in the 1st century A.D.) includes the names and partial descriptions of about six hundred. His work remained authoritative for fifteen centuries, and was continued on the one hand through the herbalists like Gerard and Culpepper in England, and on the other hand through such early botanists as Celsuspinus into the independent—doubtless too independent—science of botany.

In connection with medicinal plants there are many interesting chapters of history with which the student should make himself acquainted—the romantic stories of the old traffic in vegetable poisons; the magicians' use of narcotics and excipients; the mystical doctrine of Signatures (q.v.), according to which plants bore signs indicative of their virtues; the gradual decay of herb gathering and the loss of much valuable information; the record of the old uses of plants in both technical and popular names, such as *Pulmonaria*, *Sanicula*, *Tussilago*, and wound-wort, *serrv-grass*, *goose-weed*; the additions to the British flora by such importations as *belladonna*; the elimination from the modern pharmacopoeia of many vegetable drugs whose value was only fanciful; the relegation of others to the list of simples; the modern discovery or rediscovery of the potencies of *Calabar bean*, *cinchona*, *cochineal*, and many more.

**DISEASES OF PLANTS (Phytopathology).** Scientific investigation of the diseases of plants has not till recently been so widely and systematically followed up as the economic importance of the subject deserves. Our knowledge, therefore, of the causes and of the conditions of disease in the vegetable kingdom is comparatively limited and imperfect. Enough is, however, known to establish the general conclusion that, though there is in many cases a close analogy between the diseases of plants and animals, the causes of disease are very different. Certain bacteria and the allied *Scleromyctes* are recognized as the active agents in the development of disease in animals, parasitic fungi are now regarded as the chief cause of disease in plants. Wet rot in the potato, rot in the bulbs of the hyacinth and the onion, gummosis in the tomato, yellows in the peach, and pink decay in wheat may be cited as the principal diseases of plants at present ascertained to be caused by bacteria.

Parasitic fungi are extremely numerous, and are as varied in their action and peculiar in the parts they affect as they are numerous. Some attack the roots, others the stem and branches, while the flowers and even the several organs of reproduction and the fruit are each liable to be attacked by some particular parasite which induces disease. They are almost always local in their action, and it is very rare to find a case in which the whole organism of a plant is affected in the sense that man and other animals are said to be constitutionally diseased. Instances there are in varieties of cultivated plants of something extremely like constitutional proneness to disease. Certain varieties of *pomegranate* and *tomato* are especially liable to decay in dew, and to become abortive or die of the affection. But such extreme cases are regarded as evidence rather of local or temporary conditions being favourable to an overwhelming distribution of the parasite and the consequent multiplication of the lesions than of the penetration of disease which takes place in the organism of animals on the introduction of a microbe into the blood.

Nor is heredity so generally recognised as a factor in predisposing plants to disease as it is ascertained to be in animals. The tenacity already alluded to in connection with the growth of bacteria is a common evil among plant epidemics. The belief, which is a universal one, that the adoption of a pure and healthy air, and the greater liability of certain varieties of the potato to succumb to disease than others, would indeed appear to be attributable to hereditary predisposition in the individual kind. But it is generally conceded that such peculiarities are indications only of constitutional weakness in the variety, not of any hereditary proneness to disease.

In the suddenness of outbreak and the rapidity with which they spread when they first appear in a country or locality, there is a strong resemblance in some respects to the diseases of animals. And this resemblance is carried further in tracing the subsequent history of notable plant diseases. They appear, like epidemics in animals, to exhaust their extreme virulence after a time. The cases of attack may continue numerous and
Frequent, but the type is less severe, the disease extends, and the fungus disease of 1865 has continued annually in greater or less severity since that time; but from that year, and the two or three years immediately succeeding, it has ceased to be so formidable. Other instances might be mentioned in illustration of this resemblance in connection, for instance, among animals—the vine disease (Oidium), the hollyhock disease (Puccinia malvacearum), the celery disease (P. Apus), all of which made their appearance suddenly with such virulence and widespread rapidity as to threaten extinction of the crop, but, are now sources of neither trouble nor alarm.

The direct action of parasitic fungi in causing disease in plants is through the mycelium or spawn injuring the host plant, either by depriving them of nourishment by impairing their power of assimilation, or by abnormally accelerating or retarding growth. The extent of injury inflicted is extremely variable, in some cases exterminating in degree, and in others, though widespread and general, having little ill effect upon the health of the subject. Adverse climatic and other circumstances—such as unsuitable temperature, excess of dryness or moisture in the air and in the soil, deficiency of light, the presence of deleterious elements in the soil or of noxious gases in the atmosphere—by debilitating the plants render them more liable to attack, especially to the larger of the parasitic fungi.

The effects of disease in plants are extremely various. One of the most common manifestations of the presence of parasitic fungi in the tissues is hypertrophy in the parts affected. This may be either local or general; the roots, the stems, the leaves are all liable to this peculiar disorder. Many of the conifers are particularly subject to hypertrophies in disease. The so-called Cedar-apples of the United States, which occur in great abundance on the branches of Juniperus virginiana, are caused by the spawn of Gynnosporangium macrosporum. They are reniform tumours, and, as has been pointed out by Professor Farlow, originate by the mycelium entering a leaf and growing downward into the bark of the smaller branches. Its presence acts as a source of irritation to the cells. This is followed by the spawn of Metis to which the tree is subject to hypertrophies caused by the spawn of G. clavariiforme. This is frequently to be observed in Britain, and the enlargements are of a very persistent character, and in effect impede the supply of sap to the branches beyond them. Similar tumours occur on the branches of the silver fir, which are caused by the spawn of Pสยdermium clatinum. But the most remarkable example of hypertrophy in connection with the diseases of any of the conifers is that which occurs in the larch disease, which is caused by the spawn of Peziza catalica. The presence of the spawn threads in the cortex, cambium, and woody tissues causes their death; but hypertrophy of the tissues of the surrounding parts is set up. The death and fissuring of the bark of the affected parts follows in due course, the latter eventually dies, and sooner or later the tree succumbs to the disease. There are many other examples of this form of plant disease, nor are they peculiar to ligneous plants, but occur in humble herbaceous parasites, such as the violet, garden strawberry, species of Anemone, ranunculuses, and even in grasses; but space will not permit of more extended notice of particular cases.

Finger-and-toe, 'Anbury,' and 'Chub-root' are the common names given to a disease which attacks the stems of artichokes and to a lesser extent of the important natural order of Cruciferae. It assumes the form of tumours on the roots gener-
by placing the promycoelid spores of the Puccinea (wheat-mildew) on the barberry produced Elyeium berberidis, the mildew which frequently attacks that shrub. Since that time De Bary, Hartig, Plowright, and others have demonstrated that sixty or more species of mildews have a heterocisual habit, and further investigation will doubtless reveal many more.

Cures for plant diseases are as yet empirical rather than scientific. In many cases the subject affected is fatally smitten before evidence of disease is visible. While in what is one of the most common phenomena of plant disease, is the fructification, the final stage, of the parasite. The mycelium, whence the mildew springs, is working its deadly function on the plant in parts which external remedial applications cannot effectively reach.

In many cases of plant disease the affected subject dies without any apparent cause; investigation after death may discover it, but too often also it reveals the fact that our knowledge does not enable us to prescribe a cure. Internal remedies and the means of exhibiting them are yet undiscovered. Some plants are attacked by the mildew—that is, they destroy the pest without injuring the foliage on which it preys—but do not always eradicate the disease. London Purple and Paris Green, both having copper for their base, are very effectual external remedies, but require to be used with caution, as they are dangerous to plant-life. There are many other preparations and compounds obtainable which are more or less effectual in destroying parasitic fungi, but the only safeguard against attack appears to be the maintenance of the plant in perfect health. By this means we will be able to prevent, except it is epidemic or all-pervading, as in the case of the potato disease.

There are separate articles in this work on plant-diseases at Anbury, Enecot,RPannla, Bush, Shurt, and under the names of the plants affected—e.g. Potato; and on the various insect-pests which induce diseases, such as the Aphides and Phylloxera. See also articles on Pesthouse, Rrath, Der Pyrokranken (2d ed. 1886); Frank, Die Krankheiten der Pflanzen (1880); Harig, Lehrbuch der Baume (1882); Costa, Phycotomie Pathologique (1877); J. Pilet, Enzyme (1880); H. Mannert, Ward, The Diseases of Plants (1889); and Professor Plowright in the Gardener's Chronicle for 1891.

PLANT-LORE. Apart altogether from the more or less vague and valueless symbolism, direct or indirect, understood as the Language of Flowers (q.v.), there is an abundant store of traditionary lore associated with all kinds of trees, plants, and flowers. The study of this throws much light on many puzzling survivals in popular folklore, and Mannhardt (1831-80) and Mr. J. G. Frazer have shown its importance for part of the problem of primitive religion. It is not infrequent among Australians and Red Indians to find the Totem (q.v.) taking the form of a plant or tree, and for these reasons some ingenious mythologists have been led to derive from the association between the ancient sacred invidiate wood and the later royal forest—a ludicrous descent from the god to the game-keeper. The oak-worship of the ancient Druids, the sacred fig-tree of Romeus in the centre of Rome, the Ficus religiosa of India, and the sacred groves of the Semitic and pro-Semitic races still surviving at Carthage a century after Augustine are ready examples of tree-worship from sufficiently wide centres of civilization. The primitive mind of the savage readily conceives of a tree as animated by a conscious soul cognate with his own, and he may in his mind form an outward organism or merely its characteristic dwelling-place. Hence trees have their place in the doctrine of fetishism, of idolatry, and the upward development of religion. Buddhists do not include trees among sentient beings possessing inner life, but in their doctrine of the transmigrations of the soul natural in the outward organism of the tree, and Buddha himself was such as often as forty-three times during his transmigrations. The reverence paid to the famous Bo-tree (q.v.) shows how fundamental a fact is tree-worship, which undoubtedly formed a large part of the old indigenous religion amalgamated with the new philosophical faith. But none the less are the sacred trees and grove to be found within the range of Semitic and Aryan influences, and the instinctive revival, even under the shadow of purer rites, of the Cannaanotic Ashera worship proves how deeply they were impressed in the early mind. From all sides we find evidence at once of the great antiquity and uniformity of the worship of trees, whether for the services they render to man, for their venerable antiquity, their form, for particular qualities ascribed to them containing the seeds of fire and fertility, of the life and death of the world, as in the mountain-tops, or for their association with certain phenomena, as plagues and pestilences, or certain events in the history of the homestead. In the growth, life, decay, and death of the plant the primitive man easily sees an analogy to his own, and he may deduce from it the polarity of the death and resurrection of the world; hence the philosophical significance of the widespread rustic rites associated with marriage and with the birth of children. The custom of scattering flowers and the fruits of the field over the footsteps of a newly-married pair conveys an obvious reference to the belief in the transmogrification of plant-life after the death of the individual—the example of animism to which scientific botany has been reduced from a mere tree-soul, both alike regarded as powerful to produce rain or sunshine, to cause fruits to spring and cattle to easily bring forth their young. A still higher generalisation gave a belief in a genius of plant-life or forest-life, or, higher still, a genius of growth or fertility in general. This universal genius of growth was symbolised by a bush or tree, brought in triumph from the forest, gaily decked, and solemnly planted near the homestead or in the village. We have thus seen both the spirit incorporate in the tree, and the spirit mankind with his spirit-world, the spirit of the May, the Old Woman or Corn-mother of German harvest-fields, the Jack in the Green of young London sweeps, and the like. The existence of these Corn-spirits which especially haunted and protected the growing corn we see dimly recognised in characteristic ceremonies of an English harvest home, and in the German custom of leaving the
in which it adopted popular rites of an earlier religion, and subtly rebaptised them as its own. Many remnants of primitive survivals survive in the local English names of plants and flowers, chiefly in connection with the fairies, the devil, and the dead. The Virgin, the rose, and the lily, which have a great wealth of association from one corner of the earth between saints and flowers, as St. Agnes with the Christmas rose, St. Joseph of Arimathaea with the Glastonbury thorn, St. Patrick with the shamrock, the Virgin with the white lily, just as Thor had his oak-tree, Yggdrasil, the Greeks the oak, and the Druids the mistletoe. Again, historical personages and families are frequently associated with particular flowers—it is enough merely to name the orange-lily, the red and white roses, the fleur-de-lis, the planta genista, and the violet. Family and clan crests frequently take this form, as the Sir, holly, juniper; also national badges, as the rose, thistle, shamrock. More curious and interesting, although obscure, are the notions of magical properties connected as persistently with some plant as with others, as with the rue. Most prominent, for instance, among the European folk is the rue, the thorn, and the rowan or mountain-asl; but strange properties are still ascribed to the rosemary, vervain, St. John's-wort, mandrake, asphodel, and to fern-seed; and many flowers lend themselves to the humorous use of iniquities and rites, as for instance in methods of divination. The doctrine of Signatures (q.v.), of such importance in the history of medicine, opens up a special chapter of sympathetic magic, involving the belief that plants bore by nature marks indicating plainly for what diseases they were medicinally useful. The tree of paradise, of Chaldaean and other cosmogonies, the ocarinal oaks of Dodona, those trees of healing spiritually allegorised in the Apocalypse, the trees of Liberty of the French Revolution, and the sacred trees round which an Indian bride and bridegroom walk hand in hand, point unmistakably to a real sympathetic affinity between the human and the vegetable world as did the Dryads, Fauns, and Satyrs of the ancient Hellenic mythology, with their analogues our own elves and fairies of the later Middle Ages. These trees, whose lyre laid its charm on beasts and trees alike, or the Pan at the report of whose death all nature mourned aloud.

See W. Mannhardt, Ropgenmeuhl und Ropgenenhund (Danzig, 1865), Die Korndämmerung (Berl., 1868), Der Baumkultus der Germanen und der Nachbarstämmen (Berl. 1867), Antike Wald- und Feldkulte (Berl. 1877), and the posthumous Mythologische Forschungen (Straßb. 1884); A. de Gubernatis, La Mythologie des Plantes (2 vols. Paris, 1878-82); M. von Stratz, Die Blumen in Sage und Geschichte (Berl. 1875); H. Flammennem, Germanische Erntefeihe im heidn. u. Christl. Cultus (Hanover, 1875); Rev. Hilderic Friend, Flowers and Flower-lore (1884); V. Jahn, Die Deutschen Opferschneuken bei Ackbau und Viehzucht (Breisau, 1870); and J. G. Frazer, The Golden Bough (2 vols. 1890). The last work contains a distinct contribution of the greatest value to a scientific knowledge of the worship of vegetation, but it is not probable that this important theory has been carried too far, and at any rate many of its conclusions remain to be tested by the fresh generalisations of a later day. Its starting-point in the mystical story of the Seraphim in the Apocalyptic book of the Bible, Turner’s picture and the allusion in Macaulay’s Lay of the Battle of Lake Regillus. The lake occupies the site of the ancient sanctuary of Diana Nemorensis. In its grove the priest bore a sacred bough, from which whoever succeeded in breaking off the ‘Golden Bough’ had the right to challenge the priest of the sanctuary to single combat, and, if victorious, to reign in his stead. Mr. Frazer sees in this a survival of the tree-worship of the Druids, as an incarnation of the spirit of the tree, which passed continuously on his being killed into a new and more vigorous incarnation. He finds it also an evidence of
primitive human sacrifice, and identifies the Golden Bough with the mistletoe growing on the oak—the only thing in the world lying hidden in its doom. He has with unequalled learning and ingenuity traced many cognate customs in classical antiquity, as well as parallels in our modern rustic spring and midsummer customs, and finds the same names of vegetables and residues of vegetation under the various forms of the Greek myth of Demeter and Persephone, the Syrian Astarte and Adonis, the Phrygian Cybele and Attis, the Egyptian Isis and Osiris.

Planudes, Maximus. See Anthology.

Planula. See Hydrazoa.

Plaseuca, a decayed town of Spain, in Estremadura, 130 miles W. by S. of Madrid and 43 NE. of Caceres, is surrounded with double walls (1197), has a fine Gothic cathedral (1498), and a pop. of 7000. The monastery of San Yuste, to which Charles V. retired after his abdication, lies 24 miles to the east of Plasencia.

Plasma, a rare siliceous mineral, a variety of quartz or chalcedony, of a dark-green colour, black when unpolished and seen by reflected light, but very transparent when held between the eye and the light. It is very nearly allied to heliotrope or Indian jasper, and has the same compactness, more transparent, and is not susceptible of so brilliant a polish. The name is also used in biology for the simplest form of organised matter in vegetable and animal bodies, out of which the tissues are formed, especially of the blood-plasma. See Blood.

Plasmoplasia. See Cell, Myxomycetes.

Plassey (Pattle), a battlefield on the Bhagirathi River, 50 miles N. of Calcutta. The river has now eaten away the scene of the struggle. Plassey is celebrated in the history of India for the great victory gained by Clive over Suraj ud Dowlah, subahdar of Bengal, 23d June 1757, a victory which really laid the foundation of British supremacy in India. See Clive.

Plaster. See Cast, Gypsum, Building.

Plastering. The art of covering the internal faces of walls, the partitions, and the ceilings of a house or other building with plaster. It is difficult to get plaster to keep completely dry on the inside faces of external walls unless they are first covered with lathing (narrow strips of wood, see Lath). Celluloid and wood are lathed so as to hold or key the plaster. Plastering is sometimes done in two, but most usually in three coats. The first or foundation coat is formed of lime and sand (mortar) mixed with hair. This is called pricking if done upon lath, and rendering if it is spread on a bare brick or stone wall. It is crossed with deep incised lines to key the second coat, which consists of fine lime mixed with some coarse plaster of Paris (see Gypsum) floated on. The first coat should be completely dry before the second is added, but the latter is generally still a little damp when the third coat or set is put on. This last coat is usually composed of a mixture of fine lime, plaster of Paris, and a little size, and is worked so as to produce a very smooth surface. The implements used by the plasterer are chiefly trowels and floating tools, with running moulds for mouldings. Ceiling ornaments and other enrichments are formed of plaster of Paris cast in moulds. Mouldings are run in the same material.

Plaster of Paris. See Gypsum.

Plasters are a class of medicinal agents consisting of adhesive substances, spread upon leather or cloth, so as to stick to the part of the body to which they are applied. The plaster of the British Pharmacopoeia over their adhesiveness either to a combination of oxide of lead with fatty acids, or to the presence of a tenacious resin, or to both. The most important are lead plaster, or diachylin, which enters into the composition of many of the others; resin and pitch plasters; belladonna and opium plasters; mercury and ammoniated mercury and mercury plasters; and cantharides or blistering plaster. Some of the tenaciously adhesive of plasters (not in the Pharmacopoeia) are made with preparations of indiarubber. Court or sticking plaster, for dressing slight wounds, consists of a thin layer of isinglass spread upon silk, and differs from the others mentioned in requiring to be softened with warm water before it will adhere; Goldbeater's Skin (q.v.) is also used for the same purpose. They are employed with two distinct aims—viz. to act mechanically, as by affording artificial support to weak muscular structures, by preventing threatened or actually occurring excoriations, by protecting parts already excoriated from the action of the air, &c. and to act medicinally as counter-irritant, stimulant, diuretic, alternative, anodyne, &c.

Plastilina. See Clay.

Plata. La. See Argentine Republic, La Plata, La Plata (Rio de la Plata).

Plata (Gr. Platian), a city in the western part of Attica, on the borders of Attica, and at the foot of Mount Cithera, 6 miles from Thbes. In 480 B.C. it was destroyed by the Persians, because the inhabitants had taken part with Athens in the battle of Marathon; but in the following year it was the scene of the glorious victory won by the Lacedaemonian Greeks, under Pausanias and Aristides, over the Persian horses commanded by Mardonius. In the third year of the Peloponnesian war (429) it was attacked by a Theban-Lacedaemonian force, and heroically defended itself for more than two years, until it was starved into surrender; the little garrison of about 250 men were put to the sword, and the city was razed to the ground. Such of the Platans as escaped were hospitably received at Athens. By the treaty of Antalcidas (387) their children were allowed to go back again, and rebuild their city, after an exile of forty years; but they were again driven out by their implacable enemies the Thebans; and half a century elapsed before the victory of Philip of Macedon at Chaeronea enabled the Platans to finally return to their homes. After this the city was invested by the Lacedaemonians, 142 B.C. A.D.

Plaques. See Tablelands.

Plate-mark. See Hall-Marks.

Plate-powder, a composition of Rouge (q.v.) and prepared chalk used for cleaning gold and silver plate and plated articles. A gray plate-powder is also sometimes made by levigating quicksilver with twelve times its weight of prepared chalk; it puts a remarkable brilliancy on silver-plate, but is very injurious to it.

Plating signifies the covering of an inferior metal with one of the precious metals, the object being to give the appearance of silver or gold to articles chiefly intended for table use. Previous to the introduction of electro-plating (see Electro-Metallurgy) the method generally pursued was "soldering"—soldering on the borders of a plating-furnace—soldering on to one or both sides of an ingot of the baser metal a thin plate of silver. See also Tin-plate, Galvanised Iron.

Platinotype. See Photography.

Platinum (sym. Pt; atom. wt. 197.4; sp. gr. 21.48 to 21.50) is one of the 'noble metals.' It is found only in the native state, usually occurring in small globules. The plasters of the British Pharmacopoeia owe their adhesiveness to a combination of oxide of lead with fatty acids, or to the presence of a tenacious resin, or to both. The most important are lead plaster, or
except in association with platinum. Sometimes, however, it is found in masses of the size of a pigeon's egg, and pieces weighing ten or even twenty pounds have occasionally been found. It was originally found in the Spanish gold-mines of Darien, but is now chiefly obtained from the Ural Mountains, although it has also been found in Peru, Colombia, San Domingo, California, Oregon, Canada, and Bororo.

There are two modes of obtaining platinum in the form of ingots from the crude native metal, both of which require notice. The earlier method, Occam's, which was used in 1827, consisted in first melting the native platinum by litharge gradually added, and a little glass to act as a flux—to full redness in a reverberatory furnace lined with clay. The sulphur of the galena is oxidised and expelled, and the liquid alloy of lead and platinum is allowed to rest for some time, to allow the lead to precipitate, this is not affected by the preceding operations, to sink to the bottom. The upper portions of the alloy are then decanted, and cast into ingot-moulds, which are submitted to incineration; and the metallic platinum which is left after the impurities is melted and refined in a furnace of lino—_which is employed in consequence of its being a very bad conductor of heat—by means of the oxyhydrogen blowpipe. The platinum obtained in this manner is nearly pure, and very ductile and malleable.

Platinum exhibits a bluish-white metallic lustre; it is exceedingly malleable and ductile, and is very insusceptible, melting only before the oxyhydrogen blowpipe, or in a very powerful blast-furnace, such as that used by Deville and Debay (fusing-point, 1779° C.). It expands less by heat than any other metal, and it is the heaviest of all kinds of metals, with the exception of iridium (sp. gr. = 22.42) and osmium (22.48). It is unaffected by atmospheric action, and does not undergo oxidation in the air at the highest temperatures. It is not acted upon by nitric, hydrochloric, sulphuric, or fluoric acid, or, in short, by any single acid; but in aqua regia it slowly dissolves, and forms a soluble tetrachloride. In consequence of its power of resisting the action of acids it is of great service in experimental and manufacturing chemical processes, platinum spatulas, capsules, crucibles, &c., being employed in every laboratory. Platinum is, however, corroded if heated with the alkalies or alkaline earths, and especially with a mixture of nitrate of potash and hydrated potash, an oxide being formed which combines with the alkaline bases, and constitutes the non-inflammability and the non-oxidisability by atmospheric action, it is in great demand for electrical as well as for chemical apparatus; and the recent introduction of platinotype processes in Photography (q.v.) has caused so great a demand for platinum that its price has come up from about 35s. per oz. in 1880 to 55s. in 1889, and 80s. in 1890.

The form of the metal known as _spongy platinum_ has been already noticed. The metal may, however, be obtained in a state of subdivision much like its native form, by precipitating the acid double chloride of platinum and ammonium—viz. in the state known as _Platinum Black_. In this form it resembles soot. It may be prepared in various ways, of which one of the simplest is to boil a solution of bichloride of platinum, to which an excess of carbonate of soda and a quantity of sugar have been added, until the precipitate formed after a little time becomes perfectly black, and the supernatant liquid colourless. The black powder is then washed with water, washed with water, washed with water, and then dried gently. In its finely comminuted state, either as spongy platinum or platinum black, it possesses a remarkable power of condensing and absorbing gases, one volume of platinum black being able to absorb more than 160 volumes of oxygen. This property is of great importance in the production of certain _oxygenated_ compounds, such as oxygenated petrol (known since 1880 as_ 'divine' _or _oxygenated_ petrol). It was used as an antiseptic and disinfectant in the first world war.

Platinum may be easily alloyed with most of the metals, the alloys being in general much more fusible than pure platinum. Hence care must be taken not to heat the oxides of metals of easy reduction, such as lead and bismuth, in platinum crucibles, as the metal, which is not affected by the crucible, would be destroyed by the fusion of the resulting alloy. An alloy of platinum, iridium, and rhodium is found, by the investigations of Deville and Debay, to be harder and capable of resisting a higher temperature than the pure metal, and hence is admirably adapted for the formation of crucibles, &c.; but it is not now in the market.

There are two oxides of platinum, a protoxide, PtO, and a binoxide, PtO₂. The _sulphides_ and _chlorides_ correspond in number and composition to the oxides. Of these compounds the tetrachloride, PtCl₄, alone requires notice. It is formed by dissolving platinum in aqua regia, and evaporating the solution to dryness; and it is obtained as a deliquescent, reddish-brown mass, which forms an orange-coloured solution in water, from which, on evaporation, it crystallises in prismatic crystals. It is freely soluble in alcohol and ether. A solution of this salt is much used for the recognition and determination of potash and ammonium.

Plato, the great Athenian philosopher, was born during the early years of the Peloponnesian war, most probably in 427 B.C. Diogenes Laertius (q.v.), in his gossipping _Lives of the Philosophers_, and other writers of the Christian era have handed down a considerable amount of detail respecting his life, but most of it is of very doubtful value. An attempt went on, legends gathered round a famous name; and many of the authorities used by Diogenes were in all probability, like Diogenes himself, almost entirely wanting in critical capacity. According to one account Plato was born in Athens itself, according to another in the island of Euboea. He was the son of one Aristocles, and was the nephew of his father Aristo, who was said to be descended from the god Poseidon; whilst the family of his mother, Pericleon, claimed kinship with Solon, and through Solon with Neleus, a son of Poseidon. His namesakes are the double Platos of the Platonic ancestry was not sufficient for the admirers of the 'divine' Plato. Diogenes tells us on the alleged authority of (among others) Speusippus, Plato's own nephew and successor in the academy, that the son of his uncle, the Platonist, was that his real father was Apollo, and that the god appeared in a vision to Aristo, who thereupon kept away from his wife till her child was born. Plato's
birthday was celebrated on the same day (at the end of May) as that of Apollo himself. Bees from Hymettus are said to have fed the infant with their honey. Plato was originally named after his mother, named Theone, and his philosopher-king teacher is said to have called him 'Platón,' because of his broad shoulders, though others say he got this name from the breadth of his forehead. There is a story that he wrestled at the Isthmian games. He cannot well have escaped military service during the hundred years of the Peloponnesian war. In youth he is said to have written poetry, and this we can easily believe: a few epigrams in the 'Anthology' are ascribed to him. With regard to his philosophical education we have the important testimony of Aristotle (Metaph. i. 6), that from his youth he had been familiar with Cratylus, a follower of Heraclitus, and that the other philosophic influences under which he came were those of Socrates and of the 'Italics' schools—i.e. Pythagoreans and Eleatics.

Critias (afterwards one of the 'Thirty Tyrants') was regarded as Plato's and his brother's first disciple. His youth was passed amid the disasters and failures of the Athenian democracy; and the martyrdom of the teacher who had inspired him would not tend to increase his sympathy with that form of government. After the death of Socrates he seems to have stayed some time at Megara, where Eudoxus, who had been one of the Socratic circle but belonged also to the Eleatic school, had established himself. Eudoxes developed the Eleatic philosophy in the direction which Zeno ("the father of logic") had begun. He was the man, after Aristotle's time, who was to be considered logical questions. His school was known as the 'Dialectical' or 'Eristic'—i.e. 'disputatious.' This sojourn at Megara was doubtless an important stage in the development of Plato's thought. Having left his native Megara, he seems to have travelled to Athens in 384 (he is said to have taken part in a Corinthian campaign, or whether he did not return to Athens till ten or twelve years after the death of Socrates. During this period of his life he is said to have undertaken extensive travels, and to have visited Cyrene, Egypt, Italy, and Sicily. The visit to Sicily is almost certain; visits to the Magi and the Persians, the Babylonians, and the Hebrews are undoubtedly fictions of a later age, which supposed that wisdom could only come out of the Orient. The Athenians of the time of Dionysius in Syracuse probably helped to suggest the pictures of the tyrant in the Republic and Gorgias. On his way back from Sicily Plato is said to have been seized by order of Dionysius and said as a slave in Aegina, but to have been ransomed by a certain Areus. The residence of Athens has been variously assigned to the years 389 and 387. Plato now began to teach in the Academy (g.v.), a place of exercise in the western suburb of Athens, planted like a grove, and named from the hero Academus. There and in his own garden, which was adjacent, he gathered round him a band of disciples, teaching them probably, like his master Socrates, mainly by conversation, and embodying the results of his thinking and teaching in his written dialogues. Two more visits to Sicily interrupted the quiet of these later years. Soon after the death of the elder Dionysius (369 B.C.) he was summoned by Dionysius the tyrant of Syracuse to become his philosopher-king, in the hope that he might convert the younger Dionysius to philosophy, and so realise the dream of a philosopher-king. The young despots welcomed him warmly, but soon became weary of serious discussions, quarrelled with Dion, and finally had him put to death. This task was not less task. A third journey to Sicily (about 361) was undertaken in the vain attempt to reconcile Dionysius to Diom. Plato's own life, it is said, was only saved from the tyrant by the intercession of the Pythagorean Archytas. On his return to Athens (360) he again resumed his teaching and writing, till, after a peaceful old age, he died 'in his eighty-first year' at a wedding-feast (347). He was succeeded in the Academy by his brother's son, Speusippus; but his greatest disciple was Aristotle, who must have come under his influence after the return from the second Sicilian voyage.

Of Plato's philosophical writings none apparently have been lost; but along with undoubtedly genuine works there have come down to us others whose authenticity is open to question. Thrasyllus, a scholar of the time of Augustus and Tiberius, concluded the 36 dialogues traditionally ascribed to Plato to be genuine, rejecting a few quite unimportant writings as spurious. This 'canon of Thrasyllus' probably represents the tradition of the Alexandrian library. Aristophanes, one of the Alexandrian librarians (about 264 B.C.), had arranged similar dialogues by Plato according to the groups of three, following the analogy of Attic drama. Plato himself suggests at least two such trilogies—viz. Republic, Timaeus, Critias (unfinished); Sophist, Statesman, Philosopher (never written). Thrasyllus adopted an arrangement in tetralogies, making nine groups of four, only one of which groups (viz. Euthyphro, Apology, Crito, Phaedo) which gives a connected picture of the trial, last days, and death of Socrates) is anything but extremely artificial. Grote accepts all the works in the list of Thrasyllus. To others it appears that the Alexandrian library had every means of obtaining a genuine collection of Plato's writings from his successors in the Academy; but almost all other modern scholars reject the Epistles, some of which may, however, be very early forgeries. And the authenticity of the works that are not commonly admitted—especially in the case of the Translations, the Marcus Aurelius, and the Diodorus—are of a question. Fortunately, the more important works are the least open to question. We have Aristotle's statement that the Laches were written by Plato after the Republic. Beyond that we can only conjecture the order in which the dialogues were written; and the hypotheses of different scholars have varied greatly. We may safely put aside the theory of Schleiermacher (with whom the modern critical study of Plato begins), that Plato quite early in life had formed a complete system of philosophy in his mind, and that the dialogues were published by his disciples in order intended to unfold this system gradually to the world. It would be more true to say that Plato never had any completely formed system, and during a long life of speculation his opinions must have undergone modification. We cannot, indeed, without some difficulty, follow our author's order in his attempts to prove them. The dialogues are divided into series representing exactly his mental development (as K. F. Hermann and others have attempted); but the student may most probably consider them in groups, suggested by the different influences that act upon him, and especially by his changing attitude towards the teaching of Socrates. Each of all would come those short dialogues in which is so far as we can judge by comparing him with
Xenophon, Plato does not go beyond what the actual Socrates might have said. Such are the dialogues which deal with some particular virtue; the Protagoras, Socrates questions the beautiful and modest youth Charmides as to what the virtue of modesty or 'temperance' is. In the Laches he questions the soldier Laches about courage. The most important of this group is the Protagoras, in which Socrates argues against this follows: Xenophon says that it is not identical with knowledge. Some of these slightly dialogues may have been composed before the death of Socrates; Diogenes Laertius tells us that Socrates on hearing Plato read the Lysis (which deals with friendship) said: 'O Herocles! what a lot of lies the young fellow has told about me.' Ancient tradition made the Theaetetus the earliest dialogue; but this almost certainly belongs to a later period, though earlier than the Republic. The Apology, or 'Defence of Socrates on his Trial,' has probably more historical accuracy than any other composition of Plato's (Plato tells us he was present at the trial), and may have been written soon after the death of Socrates. The Euthyphro (concerning piety) and the Crito (Socrates in prison) may belong to the same period. The Phaedo, however, even though a conversation on the immortality of the soul, is probably of later date, as it implies the theory of ideas, and may be assigned to a time after Plato's visit to Sicily—i.e. after he had come more strongly under Pythagorean influences. Some modern scholars, having given greater stress on the 'Mystic influence,' assign the great metaphysical dialogues (Por- menides, Theaetetus, Sophist, Statesman) to the time between 399 and 386, when Plato began his teaching at the Academy. Others, with more probability, consider these dialogues and the Philebus to belong to the school's later period of thought, and this opinion is gaining ground. The Theaetetus, Symposium ('Banquet'), Gorgias, Republic, Phaedo, in which (along with the Theaetetus) Plato's literary skill is at its very highest, may perhaps be all assigned to the period of his life after forty, but on his own showing. In his own comments on his own characters ascribed to Socrates are probably represented with historical and, at least, with dramatic truth; but theories are introduced which betray strong Pythagorean influences. We must also bear in mind the theory as to beauty, that there is not 'sensation' (or 'perception'), as Protagoras and his followers suggest: sensation alone gives us no objective certainty, valid for every one. Nor is it 'opinion.' Opinion may be true, but has no certainty. A man only 'knows' when he has got at the reasons or causes of things, when he sees facts not in an isolated way, but connected by the 'chain of causation' (Mēnēa): he must be dealing with what is permanent and universal. What then is this? Plato's answer comes to be found in the theories of the Ideal or 'Form,' or 'integer' 'form,' or 'shapes,' and so 'kinds.' The analogy of sculpture may help one to understand how the Greeks came to regard 'the form,' in contrast to the 'material,' as the essential element.) This theory, following Aristotle's guidance, we may consider a development of the Socratic 'universal conception,' and also of the Pythagorean doctrine of 'numbers.' By this theory Plato seeks to reconcile the opposing views of the Heracliteans and of the Eleatics (q.v.). According to the Heracliteans, one, the universe is the manifold, the changing, have their place in the universe, the former in the world of ideas, the intelligible world, with which 'science' deals, the latter in the world of sense, with which mere 'opinion' is content. In the Republic Plato elaborates this theory of knowledge: we have a symbolical representation of it in the famous image or 'myth' of 'the Cave.' The majority of mankind are pictured by him as prisoners in a subterranean cavern, chained with their backs to the fire, looking up the rocky wall and mistaking them for realities. The turning round of some of these prisoners to the light, and the timid ascent up the steep slope to the mouth of the cave, and the gradual training of their eyes bewildered in the sunlight to see the real things in the upper world, and finally to look
The Timaeus is the one work which Plato has devoted to the philosophy of nature; and though it has exercised directly and indirectly an enormous influence over science and philosophy, as it has so largely attracted mystical and theosophical commentators, in Plato's own view it occupies a very subordinate position. We are again and again warned by him not to expect strict truth, but only approximations and figurative statements. He knew that the notion of 'emotions,' which plays so great a part in later philosophy is latent in the Timaeus. The Cosmos, or order of the universe, is the 'one only-begotten' image of God, its father and creator (Demiurgus—i.e., artificer). The Creator was good, he could not not make the world as good as himself; but no created or visible thing can be perfect. The material out of which the orderly world is made introduces imperfection into it. (This conception of matter as evil had a potent influence in later times, especially when combined with Oriental ideas—e.g., in Gnosticism, &c.) So, too, the eternal Creator could not make the world eternal like himself, and in making it made Time, the 'moving image of eternity.' To the obscure details of Plato's cosmology and physics it would be unprofitable to refer here. Cosmology is again partly introduced by a group of ideas (the Latin equivalent of Plato's 'ideas'). But the philosopher must not remain in the region of the various special sciences: he has the passion for unity and universality. Plato has a vision of the true science which is above all particular sciences, and is the unity and 'coincidence' of a special science, and this he calls in a special sense 'dialectic,' which does not like mathematical thinking need the help of sensible images, but deals with 'ideas' alone in their relation to one another and to the highest of all, the 'idea of the god.' These ideas are not mere concepts of our minds: they are, in Plato's phrase, 'the most real existences.' The extreme form of mediaeval 'Realism,' according to which universals are prior to and more real than particular things, is a crude version of Plato's doctrine. It is indeed an adaptation of Platonist philosophy to Christian teaching for which Plato's system provides no account, if the ideas are called 'the thoughts of God,' but the phrase is perhaps less misleading than many others which have been used about them. Plato does speak (in Republic, x.) of God having 'made' the ideas, as a human artist makes things by imitation of them, but he is then talking in pictorial language. God in Plato's system is rather the 'idea of the good,' the good-in-itself, which is the cause alike of knowing and of being, as the sun in the visible world is the cause both of light and of life. In the Timaeus the world is said to be fashioned by the Creator or Artificer after the pattern of the ideas; but here also the language is figurative. Plato's 'ideas' must, however, be thought of both as 'real kinds' and as archetypes. Plato's presentation of his theory varies: most probably the theory itself underwent much modification. Parmenides was one of the objections made to it are the same as were afterwards urged by Aristotle—a remarkable instance of a philosopher criticizing himself. The relation of the hierarchy of the ideas to the phenomena of the gods as conceived by Plato has worked out by Plato. Dialectics remains only a ideal science. The true dialectician is he who will see things in their unity (compare Mr Herbert Spencer's definition of philosophy as 'completely unified knowledge'): he will also 'divide things rightly according to principles.' The highest faculty of philosophy is a bringing together and a dividing (synthesis and division). In this we may recognise the germ of Aristotle's 'induction and deduction.'
(‘Righteousness’ would perhaps be a better word) is not the virtue of any special part, but of the whole soul, and is defined as ‘every part doing its own work and not interfering with the others.’ To arrive at the nature of Justice (the professed object of the discussion) the Platonic Socrates has turned from the Supreme to the latter letters—i.e. from the individual to the state, where human nature can be seen ‘writ large.’ Wisdom is the virtue of the rulers, Courage of the warriors, Temperance or Moderation is the harmony resulting from the obsequity of the lower to the higher, and Justice, which is the whole state, that the whole state would require a special ruling caste, and the only true rulers in Plato’s opinion are philosophers. Plato allows that there may be ordinary virtues resulting from custom or right opinion (cf. Meno and Phaedo), but the higher type of conduct must be bound up with the highest type of knowledge. Those alone who have the philosophic nature (which is sometimes described by him as the passionate love of truth) are the proper rulers in a perfect state, and in the philosophic nature all virtues are contained. Socrates, the Areopagite, (the parent of so many ‘Utopias’), besides the paradox of the philosopher-king, the other paradoxes by which Plato startled his contemporaries were (1) that men and women should have the same education and the same pursuits, and (2) that the whole state should be turned into one family with the family abolished. All things were to be in common; and the breeding and rearing of the citizens was to be entirely under the control of the philosopher-rulers. Just as in his theory of knowledge Plato’s ideal is unity, so his political ideal is that the state should be as much as possible one, one as a family is, or rather as one individual is. All are to be ‘members of one body.’ Some of the features in Plato’s ideal state were doubtless suggested to him by the Pythagorean brotherhoods, many of them by the actual institutions of Sparta. In fact, Plato’s ideal state might be described as a combination of philosophy with Spartan military discipline. Without the philosophy we have an inferior form—the Spartan state, or ‘tyranny,’ in which not philosophy but military honour is the ruling principle: and the ruling principle is vacuity. Lower still is democracy, the equality of good and bad alike; and worst of all is tyranny, the rule of the ‘wild beast element in man.’ In the Statesman Plato gives a beautiful analysis of political conditions, recognising both a better and a worse form of democracy, and placing both below aristocracy, but above oligarchy: in the true state the number of the rulers matters not, if only they have ‘the science of ruling.’ In the Laws he elaborates a second-best state, giving up communism as too difficult of attainment, and proposing a complete equalisation of property. In the Laws also he praises ‘mixed government.’

In the earlier part of the Republic Plato discourses on the principles of justice, turning the discussion from the Hesiod to the Greek ‘Bible,’ but Plato objects to much in the poets and in the popular religion as false and immoral. Music and poetry should be simple (here again the complex, the manifold, is of the nature of evil), and should imitate only what is good, hence dramatic art is digressive and objectionable. Towards the end of the dialogue he goes further, and objects to all ‘imitation,’ whether in painting or in words, as being only a copy of the so-called real things, which are themselves only a copy of the truth itself—the true beauty and so drives the poets from his ideal state. Aristotle’s Poetics may be regarded as in part a ‘Defence of Poesy’ against Plato’s criticism. Why, it has often been asked, has Plato, himself so great an artist, dealt so Puritanically and so unsympathetically with art? Partly, perhaps, because the first steps in reflection about art, as about religion, imply a certain withdrawal from the sway of that to which is to be criticised and understood. But the Republic gives only one side of Plato’s thought on art. In the Symposium (in which the bungling Pan-plebeian praise Love in turn) and in the Phaedrus ‘the beautiful’ occupies the same place that ‘the good’ does in the Republic. Plato is after all a true Athenian, and thinks of the good under the form of the beautiful. ‘Beautiful-and-good’ is the Greek equivalent of ‘beautify’ (in which the bananas show its best sense). ‘All that is good is beautiful,’ he says in the Timaeus. The true lover is akin to the philosopher, and loves the beauty of the soul rather than the beauty of the body, and ascends from the love of the many beautiful to the love of absolute beauty. There is indeed a strain of asceticism in Plato’s view of life; but there is none of the Cynic contempt for the beauty of the human form and for the graces of social intercourse. In the Phaedo Socrates speaks of the body as ‘the prison-house of the soul.’ The question is somewhat different from Socrates awaiting his end: and in the Republic the body has to be carefully trained that it may be a fit servant of the soul, and the young are to grow up amid fair sights and sounds.

Plato’s influence on human thought has been even more widely diffused, but is more difficult to measure than that of Aristotle. The various schools of the Old, Middle, and New Academy played their part. Scepticism was assimilated into Stoic, especially the later Stoics, borrowed much from him. Perhaps no school of Greek philosophy was unaffected by him. In Alexandria Jewish thinkers fell under his fascination (see Philo); and Christian theology is largely Platonic. But the Alexandrian Platonists and the Neoplatonists (q.v.) differ from Plato himself in making the Timaeus the centre of his system. The writings ascribed to Hermes Trismegistus and Diogenes the Areopagite belong to the Neoplatonic period. The latter was translated by Eriugena in the 10th century, and Platonism reached the western world in the middle ages through the medium of those mystical writers. The Italian Renaissance and the revolt against Scholastic Aristotelianism revived the study of Plato’s own writings; but the enthusiastic Cambridge Platonism of the 17th century were both after the Neoplatonic manner, and, like the medieval ‘Aristotelianism,’ brought more veneration than understanding to the interpretation of the philosopher. Of all Plato’s disciples (to adapt a famous saying) perhaps only one had understood him—Aristotle—and he did not. His criticisms are often strangely unsympathetic. Yet Aristotle’s whole system gives a more trustworthy clue to Plato’s real philosophical significance than the state of the art from mystical interpreters whose zeal was not always according to knowledge (see first edition).

The first printed edition of the Greek text of Plato is the Aldine (Venice, 1513). Plato is constantly cited according to the pages of the edition printed by H. Stephanus (Paris, 1578). The best and most convenient texts are those of Stallbaum, of Baüer, Orelli and Winckelmann, and of K. F. Hermann. The critical edition by S. Taylor (1845) is not yet complete. Plato was first printed in the Latin translation by Fideno (Flor., 1483), which was the best outcome of the Platonic revival, and is the basis of the ordinary Latin versions. A complete English translation and a new critical text by Taylor, ‘the Platonist’—i.e. Neoplatonist, in 1804 (including nine dialogues translated by Sydenham about 1759). The poet Shelley translated the Symposium (included
Platte, or Nebraska, an alluvium of the Missouri River, is formed by the junction in west central Nebraska of the North and South Forks, which rise among the Rocky Mountains, in Colorado, are respectively some 800 and 550 miles long, and are not navigable. The general course of the Platte is eastward, in a wide shallow valley, over the treeless plains of Nebraska, till it reaches the Missouri after a winding course of about 450 miles. With its forks it drains some 300,000 sq. m., but like them it is not navigable.

Platten-See. See BALATON.

Plattsburg, capital of Clinton county, New York, on Lake Champlain, at the mouth of the Oswegatchie or South Fork; 31 miles N.W. of Montreal. It has planing-mills, machine-shops, and an iron-foundry, and manufactures wagons and sewing-machines. In Plattsburg Bay, on September 11, 1814, a British fleet of sixteen vessels was defeated and partly captured by Commander Thomas Macdonough, with fourteen vessels; while a large land force, under Sir George Prevost, was repulsed by General Macomb, with 1500 men. Pop. 8434.

Plattsburg, capital of Cass county, Nebraska, is on the Missouri, about a mile below the mouth of the Platte, and 21 miles by rail S. of Omaha. It manufactures flour, wagons, engines, reed-organ, &c. Pop. (1890) 4107; (1896) 4904.

Plautus. See ORNITHORHYNCHUS.

Plauen, one of the most important manufacturing towns of Saxony, stands in the south-west corner, on the Elster, 78 miles S. of Leipzig by rail. Its chief industries are the manufacture of cotton goods, muslin, cambric, jacenet, and embroidered fabrics, with a in secondary degree cigars, paper, machinery. Pop. (1875) 28,756; (1896) 46,988.

Plautus, M. Accius (or more correctly T. Maccius), the chief comic poet of Rome, and probably among his own countrymen the most popular Roman author of any age, was born about 250 B.C. at Sarsina, a village in Umbria, a district which must at this time have been thoroughly Latinised. We have no knowledge of his early life and education, but it is probable that he came into Rome while still young, and acquired there his complete mastery of the most i:olatric Latin. Though born in the country, he introduces countrymen chiefly as subjects for ridicule; he always writes as a townsman, familiar with city life, especially among freemen, craftsmen, and the middle classes. In Rome he found employment, education, and, at the stage, of what kind precisely we do not know. In this position he saved money enough to enable him to leave Rome and start in business on his own account in the way of foreign trade; and such early thrift shows strong character and determination to rise in the world. His plays evince close familiarity with seafaring life and adventure, and an intimate knowledge of all the details of buying and selling and keeping accounts—experience probably acquired during this period. We know that he failed in business, and returned to Rome in such poverty that he had to earn his livelihood in the service of a laker by turning a hand-mill, work generally performed by slaves. At this time, shortly before the second Punic war broke out, he was probably about thirty years of age, and while in this humble condition he began to write those plays which he sold to the managers of the public games. The price paid him enabled him to leave the mill, and he spent the rest of his life at Rome. Probably he commenced to write about 224 B.C., and for forty years, until his death in 184, he continued to produce comedies with wonderful fecundity. Most of the plays we have belong to the last ten years of
his life. It is not certain whether Plautus ever obtained the Roman franchise. He was the contemporary of Nemesius and of Ennius.

His plays appear not to have been published during his lifetime, but to have been left in the hands of his friends and admirers. The critics have been prone to correct and omit passages to suit them for the stage. Almost all the prologues were written after his death. About 130 plays were attributed to him in the time of Gellius, who held most of them to be the work of earlier dramatists, revised and improved by himself. They contemned them almost as spurious. Varro in his treatise Questiones Plautianae limited the genuine comedies to twenty-one; and these so-called 'Varronian comedies' are the same which we now possess, only one, the Epidicus, being lost. Plautus' plays were immensely popular on the stage, not only with the people, but with the educated classes, and were acted, as Arnobius tells us, in the time of Diocletian, five centuries later. Plautus borrowed his plots to a large extent from the New Attic Comedy, which dealt with ideal life to the exclusion of politics; he doubtless imitated its general types of character, but he 'adapted' very freely, and infused into his borrowed framework a new and robust life, which was Roman to the very core. His perfect spontaneity, vivacity, and wit attracted all Italy. If his dialogue shows that these are the genuine fruit of his own genius. The scenes of his comedies are always laid in Athens or in some Greek town. Had he depicted the family life of Romans so corrupt, the magistrates would no doubt have interfered; but the Greek personages of his plays speak and act in every respect like Romans; they refer familiarly to places in Italy, to streets, magistrates, and customs at Rome. Not even Shakespeare is more careless about inconsistency of this kind. It is probable that Plautus wrote with great rapidity; some of his finest comedies are written through the action being too hurried to the close. Roman comedy expressed 'a rebound from the severer duties of life'; Plautus' audience were in holiday mood, and did not expect to be admonished or entertained with a display of reflection. His leading characters possess boundless animal spirits, infinite resource in difficulty, and but small conscience. His heroes show that, as Sellar says, Plautus was more familiar with the ways of 'Bitterness' than of Roman ladies. His favourite slave, whom he makes a noble youth, shows himself the slave Tyndar, cheerfully willing to sacrifice all for his young master, shows that Plautus had the power to conceive a really noble character. The charm of Plautus, lying in his genuine humour and powerful grasp of character, even deep down to the roots of his nature; he delights his readers to-day as truly as when he made Roman theatres ring with applause, or when St Jerome solaced himself in his cell by reading the well-loved comedies. His joyous sense in all circumstances of the gladness of life is the mark for all time of his master, he makes his reader look involuntarily at the bright side of things. According to Sellar, the five best plays are Aulularia, Captivi, Menæchmi, Pseudolus, Rudens. Shakespeare has imitated the plot of the Menæchmi, entirely recasting it, in his Comedy of Errors. Molliere's L'Avare is borrowed from the Aulularia.

English translations are by Thornton and Warner (1767-74), and H. T. Riley (1860). Ritchie has shown great acuteness in restoring Plautus' text, which is very corrupt (2d April 1771). The complete edition which he contemplated was continued by his pupils, G. Goets and others (1878 et seq.). See also Sellar, Roman Poets of the Republic.

Playfair, John, mathematician and natural philosopher, was born at Benvie manse, near Dundee, March 10, 1705; he succeeded his father as minister of Liff and Benvie. During his leisure hours he still prosecuted his favourite mathematical and geological studies, and communicated to the Royal Society of London two memoirs, On the Arithmetic of Impossible Quantities and Account of the Lithological Survey of Schiehallion. In 1783 he became joint-professor of Mathematics in Edinburgh University, but exchanged his chair for that of Natural Philosophy in 1805. He became a strenuous supporter of the 'Humean theory' in geology, and, after publishing in 1802 his Illustrations of the Humean Theory of the Earth (see GEOLOGY, Vol. V. p. 148), he made many journeys for the sake of more extensive observations, particularly in 1815, when he visited France, Switzerland, and Italy. The last volume of his works, published in 1819, Playfair was during the last part of his life secretary to the Royal Society of Edinburgh. From 1804 he was a contributor to the Edinburgh Review and to the Transactions of the Royal Society of Edinburgh, and wrote many important articles for the Encyclopaedia Britannica. His separate works are the Elements of Geometry (1795) and Outlines of Natural Philosophy (1812-16).

Plays. See DRAMA, THEATRE. A relic of the censorship of the press survives in Britain in the licensing of stage plays. By an Act of 1843 no plays may be acted for hire till they have been submitted to the Lord Chamberlain, who may refuse to license them in whole or in parts; the official who reads them for this purpose being the 'examiner of stage plays.' A penalty of £50 attaches to the offence of acting an unlicensed or prohibited play; and the theatre in which it is represented forfeits its license. In the United States these laws are generally inoperative; the authorities have power to forbid the representation of plays which they consider to be harmful to morality.

Plea, the answer of the defendant to the plaintiff's demand or charge. Pleas were divided formerly into pleas dilatory (where the party seeks to break down the conclusion of the action without entering into the merits of the case) and peremptory, Demurrers (q.v.), in Abatement (q.v.), special in bar, &c.; now the plea is usually Guilty or Not Guilty (see CRIMINAL LAW). In Scots law, plea means also a written statement of the legal grounds on which the party bases his case. In English civil procedure this is called Pleading; a term applied in criminal law to the accusation of the prosecutor or the answer of the accused. Pleadings have been much simplified by the Judicature Acts (1873-78). In the United States the New York legislature established a uniform procedure which has been adopted by most of the states. 'Plea of the Crown' is an old term for criminal cases. In the Houses of Parliament pleading, as in the superior courts of law, must be conducted at the Bar (q.v.).

Plebeians. See ROME, TRIBUNE.

Plebeiscite, the name given, in the political phraseology of modern France, to a decree of the
nation obtained by an appeal to universal suffrage. Thus, Louis Napoleon was chosen president, and subsequently emperor, by a plebiscite, and in 1870 obtained the sanction of still a third one (75 million votes). The word is borrowed from the Latin, but the plebiscitum of the Romans properly meant only a law passed at the Comitia Tributa,—i.e., assembly of the plebs, or 'commons,' as distinguished from the nobles. The word is often used in Britain for an attempt to secure an expression of opinion on some special point of national interest by all the inhabitants of a district—often by means of return post-cards.

Plectognathi, an order of Bony Fishes (q.v.).

Pledge. See Pawnbroking.

Pleiades, in Greek Mythology, were, according to the most general account, the seven daughters of Atlas and Pleione, the daughter of Oceanus. Their history is differently related by the Greek mythologists: according to some authorities, they committed suicide from grief, either at the death of their father or of their countrymen, or at the fate of their father, Atlas (q.v.); according to others, they were companions of Artemis (Diana), and, being pursued by Orion (q.v.), were rescued from him by the gods by being translated to the sky; all authorities, however, agree that after their death or translation they were placed in the sky among the constellations. They are, from left to right, Electra, Maia, Taygete, Alectryone, Celene, Sterope (the invisible one), and Merope. The group or constellation of the Pleiades, called the 'Seven Stars,' is placed on the shoulder of Taurus, the second sign of the Zodiac, and form, with the pole-star and the twin Castor and Pollux, the three angular points of a figure which is nearly an equilateral triangle. But, if looked at directly, only six stars are visible to the eye, though, if the eye is turned sideways, more can be seen; a good telescope shows fifty or sixty in the area. The photographic chart produced by M. M. Henry in 1888 shows 2320 stars, with nebula internixed.

The name Pleiads is frequently applied to reunions of poets in septenary groups; and this use of the word dates from the time of Poleney Philosophus at Alexandria, who treated seven Greek poets with some special attention and denominating them Pleiads. His example was followed by Charlemagne. But the name Pleiads is specially associated with a group of 16th-century French writers, of whom Ronsard (q.v.) and Du Bellay (q.v.) are the most notable, who endeavoured with marked result to reform the French language and literature after classical models. The other names are Lazzar de Balé, ambassador at the diet of Spires; Jean Dorat, a celebrated Hellenist; Amadis Jamin; EtienneJobelle; and Pontus de Thiern. In place of the two last, other authorities give Scévole de Saint Martin and Marc Antoine Maret (q.v.); and instead of Jamin, Beliace.

Pleiocene. See PIocene.

Pleochroism. In some crystals, such as some specimens of topaz, three distinct colours may be observed on looking through them along three rectangular axes. In intermediate directions intermediate tints may be observed; and this property is that of pleochroism or polychroism. In some other cases a similar range of intermediate tints may be observed, lying between two extreme tints visible along two axes (dichroic crystals—e.g., olite or sapphire d'eau, and some specimens of mica).

Plesiosaurus. See PLESIOSAURUS.

Pleistocene (Gr., 'most recent') or Glacial. See GLACIAL. The glacial epoch is the later of the older accumulations belonging to the Quaternary or Post-Tertiary division. Almost all the molluscs met with in beds of this age are existing species. The system is termed Pleistocene or Glacial according as we have reference to the character of its organic remains or to the physical conditions under which the greater part of the deposits have been formed and is related. These deposits are of very diverse nature and origin, and are subject to endless modifications, but nevertheless they show certain well-marked phases which are persistent over wide areas. Thus, throughout all northern Europe and the hilly and mountainous districts of the central and southern regions of the continent they exhibit the same general character and succession. The deposits of these regions consist for the most part of glacial and fluvioglacial detritus, which betoken the former presence of a great ice-sheets in northern Europe, and of extensive snowfields and glaciars in the mountain districts farther south. For an account of these deposits and glaciation generally, see GLACIAL PERIOD. In the regions outside of the glaciated areas the Pleistocene system is represented principally by fluviatile accumulations, enlaced into valley and mountainous, and deposits in caves. The old river-gravels, &c., are well seen in the valleys of southern England, France, Belgium, central Europe, Spain and Portugal, Italy, &c., where they occur at the surface. But when they are followed into regions in which glacial and fluvioglacial accumulation is well developed they disappear underneath or are dovetailed with them. Cave-deposits are of course met with even in glaciated regions, but in such countries no Pleistocene accumulations overlie the glacial and fluvioglacial detritus of the latest cold stage of the glacial period.

Thus, in general terms, the Pleistocene deposits of northern Europe and the mountainous regions of the central and southern parts of the continent are of glacial origin, while the accumulations outside of those areas are chiefly fluviatile. The latter were for some time believed to be upon the whole younger than the former, but the two series are now generally recognised to be contemporaneous. The occurrence of fossiliferous beds intercalated between sheets of morainic matter (boulder-clay, &c.) proves that the so-called glacial period was interrupted, and there were, though short, interglacial climatic conditions, during which the inland ice of the north retired from all the low grounds, while the great glaciers of the Alps, &c., shrank back to the inner recesses of the mountains. The organic remains obtained from fresh-water interglacial deposits in northern Europe (often termed Loess,) &c., have not only occurred in the river-accumulations of the non-glaciated tracts, and the result is that these accumulations are now admitted to be for the most part of interglacial age also. In short, the peat, river-deposits, tufs, and cave-accumulations are the equivalents in time of the glacial and interglacial deposits.

Life of the Period.—The plants and animals of the Pleistocene betoken great changes of climate—certain species indicating an extremely cold or Arctic climate, whilst others could only have flourished under extremely mild and uniform conditions. While a cold climate prevailed, such plants as Dryas octopetala, Betula nana, Salix polaris, &c., flourished in the plains of Germany, and similar northern and Arctic forms clothed the low grounds of Swithland and the north-east of England, the elder, larch, spruce, juniper, and yew, while in Northern Italy the Cambric pine flourished in the neighbourhood of Juvra, and the Scotch fir on the shores of Lake Varese, positions in which it is needless to say they could not live now. Contemporaneous with these forests flourish many fresh-water shells which are equally indicative of cold and unguinal conditions. And the same tale...
is told by the boreal and Arctic species of molluscs which occur more or less abundantly in the shelly clays of north Germany, Scandinavia, and the British Islands, and by the presence of northern forms in the Pleistocene marine beds of the Mediterranean area. The character of the land animals is quite in keeping with the evidence. Living in the low grounds of central and southern Europe at this time were reindeer, glutton, musk-sheep, Arctic fox, Alpine hare, marmot, snowy vole, mammoth, woolly rhinoceros, &c. The remains of these and several other animals are met with both in glaciated countries and in the caves and fluviatile deposits that occur in regions that never were covered with glacier-ice. The relics and remains of man himself also accompany the same flora and fauna. In strong contrast with such an assemblage of plants and animals is that of which we find abundant traces in interglacial beds and cave- and river-deposits. In northern France grew willows, hazels, ash, dwarf elder, sycamore, spindle-trees, hazels, clematis, sycamore, inachairos, i.e., &c. During the interglacial period, which flowers in winter, proves that the winters must have been very clement, and the other plants are indicative of a genial humid climate. The summers were not so hot and dry as they now are in France, and the dry-land and dry-forest conditions obtained in Germany and the Mediterranean region—although the forms of those different zones were distinguished from each other by the presence of certain forms and the absence of others. The land and fresh-water shells associated with this flora are equally indicative of genial conditions, and similar evidence is supplied by the mammalia. Thus, we find a strange commingling of southern and temperate forms which is quite in keeping with the similar association in one and the same place of various plants which no longer live together. We find hippopotamus, African elephant, hyena, serval, lion, leopard, various extinct species of elephant and rhinoceros, an extinct dwarf hippopotamus and macracterus. Contemporaneous with these were urns, black, brown stag, stag's, muntjac, roe, wild cat, wild boar, brown bear, grizzly bear, cave bear, Irish deer, &c. The relics and remains of Palaeolithic man likewise accompany this flora and fauna.

It is obvious, therefore, that the Pleistocene period was marked by great climatic oscillations. At one time the whole of northern and north-western Europe, down to the 50th parallel N. lat., was covered with a vast mer de glace, while from the Alps and all the considerable mountain-ranges of middle and southern Europe great glaciers descended to the low grounds. From ice-sheet and glaciers mighty rivers flowed all the year round, but in summer they rose in flood and inundated wide tracts, which in time became overspread with sand and loam. It was under such conditions that a boreal and Arctic vegetation clothed the interglacial plains of Europe. Considerable tracts of that region, during the last cold stage of the glacial period, appear to have resembled steppe, and to have been inhabited by jerboas (jumping hare), spermophiles, &c. The same lands, which is quite in keeping with the even, beaver, hazel, rabbit, other mammals, wild cat, wild boar, brown bear, grizzly bear, cave bear, Irish deer, &c. The relics and remains of Palaeolithic man likewise accompany this flora and fauna. 

With the advent of interglacial times such ungenial conditions of climate passed gradually away—the ice-sheet vanishing from the low grounds of north-western Europe, while the mountain-glaciers of central and southern regions dwindled to insignificance. Great migrations of plants and animals accompanied these changing conditions, the Arctic-alpine flora and northern and alpine fauna retreating northwards and retiring to mountain elevations. At the climax of interglacial times an extremely mild and genial climate, recalling that of the Pliocene, prevailed in Europe. The Canary laurel, the figs, and citrus plants, the juniper and other hardy shrubs, &c., grew as far north as Paris, in which region frost in winter was rarely or never experienced. Elephants, hippopotamuses, rhinoceroses, &c., and vast herds of bovine and cervine animals then wandered over all temperate Europe—the British area included. How often such changes of climate were repeated has not yet been ascertained, but interglacial beds occur on at least two horizons—as in France and the alpine lands of central Europe. Hence there would appear to have been at least three glacial epochs and two intervening epochs of genial climatic condition. In northern Europe only one well-marked interglacial epoch is generally admitted by geologists. But the evidence is not conclusive. It is obvious, indeed, that the preservation of interglacial accumulations of organic matter and other relics would have been severely glaciated. With the return of ice-sheet and glaciers, fluviatile and other deposits which had been laid down during interglacial times would be ploughed up and commingled with other morainic material. It is only here and there, therefore, that patches of such deposits have escaped destruction. The relics of interglacial times are most abundantly met with in countries which were beyond the reach of the ice. The closing stage of the Pleistocene was a glacial one; so that in the valleys of central and western Europe, off the oesiferous river-valleys of the last interglacial period are more or less buried under the fluvio-glacial gravels and loams of the latest glacial epochs. The latest Pleistocene deposits in the British area are marine clays containing Arctic and boreal shells. These deposits go up to 100 feet or so in Scotland.

Considerable geographical changes supervened during Pleistocene times. The proofs are seen in certain raised beaches in the maritime districts of north-western Europe, in the marine clays with their Arctic and boreal shell-sand, in the sands and loams of the Mediterranean, &c., of glacial and interglacial age, which are well developed in the British area. Again, the distribution of the mammalian fauna of the Pleistocene points in like manner to considerable changes in the relative level of land and sea. Thus it would appear that in interglacial times Europe was connected, across the Mediterranean, by one or more land passages with north Africa; while at the same time the British area was continental. Indeed, certain evidence leads to the belief that the English Channel was not interglacial sea as what is now the line of 100 fathoms. Towards the close of the last interglacial epoch, however, a considerable submergence of the British area supervened—for undisturbed interglacial shells, &c., have been met with up to depths of several hundred feet. It is noteworthy also that the low grounds of north Germany were likewise submerged just before the invasion of that region by the last great mer de glace. The cause of such changes of level has been much canvassed by geologists, and that the reindeer and its associates flourished in the low grounds of southern France, where they were hunted by Palaeolithic man. With the advent of interglacial times such ungenial conditions of climate

The text continues without any apparent breaks or errors in formatting.
the weight of the great ice-sheets which covered such vast regions in our hemisphere during glacial times may have displaced the earth's centre of gravity, and thus caused a rise of the sea in the north. Others, again, think it probable that under the influence of the great thick crust may have yielded and sunk down more or less gradually. Some, again, have thought that a thick ice-sheet would exercise sufficient attraction upon the sea to cause it to rise upon the land. It must be admitted, however, that some of the observations in this, which take place in Pleistocene times were on much too considerable a scale to be explained by any of the hypotheses referred to. If, for example, the considerable subsidence which happened just before the advent in the British area of the last mer de glace was due to the pressure of an ice sheet covering some region farther north, it is hard to understand how great confluent glaciers afterwards succeeded in covering an area lying several hundred feet below the surface of the sea. Again, if the crust of the earth were so readily deformed under the weight of the ice sheet, it is difficult to account for any of traces of contemporaneous marine action in these low-lying regions of south England and the Continent which were invaded by the great northern ice-sheet? Whatever influence the ice-sheets of the glacial period may have had upon the submerged areas near the coast, the greatest oscillations were the result of considerable earth movements, such as have taken place at many different stages of the world's history.

Pleistocene in other Continents.—In North American deposits of the same character and showing the formation as a great theatre of Europe's encountered—the glacial and interglacial conditions that characterised the latter continent having been equally characteristic of the former. The Pleistocene fauna of North America embraced Mastodon, a true elephant, species of horse, buffalo, moose, peccary, bear, &c., and gigantic extinct forms of sloth, such as Megatherium, Mylodons, and Megalonyx. In South America the Pampa deposits have yielded a large number of remains of the great sloths and armadillos (Glyptodon), besides a great variety of other species. There is abundant evidence to show that snow-fields and glaciers had in Quaternary times a considerable development in the Cordilleras, while in Punga ice seems to have overflowed much of the low grounds. In South Africa the ancient snow-fields and glaciers have left their traces in the mountains of the Drakensberg and Kravernaun. Again, New Zealand and Australia seem to have had a glacial period. Little is known of the mountains of central Asia, but old moraines and erratics have frequently been observed in the Chinese ranges, while, as is well known, the glaciers of the Himalayas had formerly a very great development.

Cause of the Pleistocene Climatic Changes.—Many speculations as to the cause of the climatic changes of Pleistocene times have been indulged in. It must be admitted, however, that none of these explanations is without its difficulties. But the theory that change in, or change of position, accounts for the facts and has gained the widest acceptance is that advanced by the late Dr Croll. According to him, the strongly contrasted climates of the Pleistocene period were the indirect result of the increased eccentricity of the earth's orbit, combined with the precession of the earth's axis. The increased eccentricity that hemisphere which had its winter in aphelion would be subject to severe cold, and its snows would not disappear during the succeeding short summer, the temperature of which would be lowered by its absence. Thus the winters of the hemisphere would be subjected to severe glacial conditions. In the opposite hemisphere the state of things would be very different, for the winter would be short and mild and snow would not accumulate. Under such widely contrasted conditions between the northern and southern hemispheres, the trade-winds, and through them the great convective movements of water, would be fully affected. The winds blowing from the glaciated hemisphere would be much stronger than those coming from the other, and the equatorial oceanic currents would thus be impelled across the equator into that hemisphere whose summer happened in aphelion. If a warm current of warm water would necessarily increase the temperature of that hemisphere, while the other would have its temperature correspondingly lowered. Owing to the procession of the equinox, however, the conditions of the two hemispheres would tend to be reversed every 11,000 years or so; so that during a cycle of great eccentricity each hemisphere would experience an alternation of extremely cold and very genial climatic conditions. The last period of high eccentricity commenced some 240,000 years ago and lasted for about 160,000 years. Some geologists have stated that the glacial period cannot be carried so far back in time. Thus, from an examination of the rate of erosion in the postglacial gorges of some rivers in North America (Falls of Niagara, Falls of St Anthony), some observers conclude that only 7000 or 8000 years have elapsed since the change of the ice age. But in all such measurements and estimates there are elements of uncertainty which render the conclusions based upon them of little value.

Antiquity of Man in Europe.—All the human relics met with in Pleistocene deposits belong to what is known as the Palaeolithic stage. Hitherto no incontestable evidence is forthcoming to show that man was an occupant of Europe before the glacial period. It is quite possible he may have been, but we lack evidence sufficient to prove this. He certainly lived, however, during the glacial and interglacial conditions described above. It is remarkable that no trace of his occupation has been met with in beds of later date than those pertaining to the close of the last interglacial epoch. If we were to judge from negative evidence (which is abundant), we might infer that he vanished from Europe during the last glacial epoch. The oldest human relics hitherto discovered in postglacial beds are Neolithic.

See Croll's Climate and Time (1875). Various objections which have been levelled against his theories have been answered by its author in his Climate and Cosmology (1886). See also G. F. Wright, The Ice Age in North America (1889), and the articles in this work on Geology, Anthropology, Man, Europe, Stone Age.

Plenipotentiary. See Ambassador.

Pleiosaurus (Gr. plesios, 'near to,' sauros, "a lizard"), the type or leading genus of a family (Pleiosauridae) of fossil sea-reptiles, which are characteristic of the Mesozoic systems. The skull of Pleiosaurus is small and depressed, with a shallow mandibular symphysis. The teeth (sink in distinct sockets) are long, slender, and cylindrical, and show fine longitudinal ridges on the enamel. The most striking peculiarity of the vertebrae is the great length of the neck portion, which was composed of 24 to 28 vertebrae, the anterior ones being generally very small. The cervical vertebrae consist of a centrum, neural arch, and two ribs, which are firmly articulated to the centrum of the vertebra, the terminal faces of which are more or less be cumulative. In the dorsal vertebrae the ribs are much elongated, forming a long neural arch; and in the tail they gradually descend again to the sides of the centrum. The tail is
much shorter than in Ichthyosaurus (q.v.). In the abdominal region the extremities of each pair of ribs are connected below by the development of the hemal spine. The sesamoids are of moderate size and widely separated. The two pairs of limbs correspond closely in structure. The humerals and femurs are comparatively short and distally much expanded; the radius and ulna, tibia and fibula are short and flat; the 'hand' and 'foot' are long, the phalanges being increased in number beyond the normal complement. The limbs were covered with integument so as to form simple undivided paddles, as in the turtle. Plesiosaurus was undoubtedly aquatic, and probably haunted the shallow seas and estuaries of Mesozoic times. Its remains have been met with frequently in a fine state of preservation, some almost perfect skeletons having been obtained from the Lias of England. Several genera of Plesiosaauridae have been determined. One of these, Clinocephalosaurus, met with

in the Jurassic and Cretaceous strata of Europe, North and South America, and New Zealand, attained a length of between 30 and 43 feet. Pliosaurs was another genus, with a shorter neck (the vertebrae twelve in number) and a comparatively larger head than Plesiosaurus. In this genus the lower jaw was sometimes nearly 6 feet long. See the Manual of Palaeontology, by Nicholson and Lydekker (1899).

Plesiis-les-Tours. See Tours, Louis XI.

Plethom, Georgios Gemistos, a Greek scholar, was most probably a native of Constantinople, and found employment in the Peloponnesus under the 'despots' Manuel and Theodore Paleologus. He was sent as a deputy to the council held at Florence in 1439, and here, if he did little for the union of the Eastern and Western Churches, he did much to spread a taste for Plato. He returned to Constantinople, and died there about 1455. See vol. i. of F. Schultze's Geschichte der Philosophie der Renaissance (Jena, 1874).

Plethora (Gr., 'fullness') designates a general excess of blood in the system. It may arise either from too much blood being made or from too little being expended. The persons who become plethoric are usually those in thorough health, who eat heartily and digest readily, but who do not take sufficient bodily exercise, and do not duly attend to the action of the excreting organs. With them the process of blood-making is always on the increase, and the vessels become more and more filled, as is seen in the red face, distended veins, and full pulse. The heart is excited and overworked, and hence palpitation, shortness of breath, and probably a sleepy feeling may arise; but these symptoms, instead of acting as a warning, too often cause the abandonment of all exercise, by which the morbid condition is aggravated. The state of plethom thus gradually induced may be extreme without any function being materially failing, and yet the subject is on the verge of some dangerous malady, such as apoplexy, or structural disease of the heart or great vessels, or of the lungs, kidneys, or liver.

Pleurisy, or inflammation of the investing membrane of the lung (pleura), is one of the most serious diseases affecting the chest, but by no means invariably, associated with inflammation of the substance of the lung, commonly known as Pneumonia (q.v.). Pleurisy without pneumonia is much more common than pneumonia without pleurisy. When both are present, but pneumonia preponderates, the correct term for the affection is pleuro-pneumonia, although it is frequently spoken of simply as pneumonia, probably in consequence of the remedies being applied mainly to it, as the more important of the two elements in compound malady.

The pleura being a serous membrane, its inflammation is attended by the same course of events as have been already described in our remarks on the two allied diseases, Pericarditis and Peritonitis. The inflammation is of the adhesive kind, and is accompanied by pain, and by the effusion of serum, of fibrinous exudation, or of pus into the pleural cavity. In the last case it is called empyema. In consequence of the anatomical relations of the pleura—one part of the membrane (the parietal) lining the firm walls of the chest, while the other part (the visceral) envelopes the soft and compressible lung, and these opposite surfaces being freely movable on one another—it follows that very different effects may be produced by its inflammation. For example, the visceral layer may be glued to the parietal layer, so as to prevent all gliding movement between them, and to obliterate the pleural cavity (similarly to what often happens in Pericarditis, q.v.); or the two surfaces which are naturally in contact may be abnormally separated by an effusion of serum between them; or, from a combination of these results, the opposite surfaces of the pleura may be abnormally united at some points, and abnormally separated at others.

The general symptoms of pleurisy are rigors, pain in the side, fever, difficulty and rapidity of breathing, cough, and an impossibility of assuming certain positions; and of these the most marked is the pain or stitch in the side, the Point de côté of the French writers. The pain, often very severe, and often limited to one small spot, is usually at the lower part of the affected side; but is occasionally felt in other parts—as in the shoulders, in the hollow of the arm pit, beneath the collar-bone, along the breast-bone, even in the loins, simulating lumbago; or, in the abdomen, so as to suggest peritonitis or hepatitis. In some cases it is altogether absent. The pain is increased by percussion, by pressure between the ribs, by a deep inspiration, by cough, &c.; and the patient is often observed never to draw more than a short and imperfect inspiration. Cough is not invariably present, although it is an ordinary symptom. It is small, suppressed as far as possible by the patient, and is either dry or accompanied by the expectoration of slight catarrh. If much frothy mucus is brought up it is a sign that Bronchitis (q.v.) is also present, and the appearance of rust-coloured spuma indicates the co-exist-
ence of pneumonia. Although the above-named symptoms, especially when most of them occur together, afford almost certain evidence of the existence of pleurisy, yet to the physician the physical signs are still more valuable, especially those that distinguish between the acute and chronic phases of the disease.

The friction-sound, characteristic of pleurisy in the dry stage in its most marked form, resembles the cracking of leather; the patient is often himself conscious of the grating sensation produced by the rubbing of the pleural surfaces; and this may sometimes be heard by the hand laid on the affected part. If fluid effusion be present the friction-sound is lost; but dullness on percussion replaces the normal resonance over the area which it occupies.

Pleurisy far more commonly arises from exposure to cold than from any other cause, especially if a poisoned condition of the blood, predisposing to inflammation of the serous membrane, is present; thus it often complicates rheumatic fever and Bright's disease; but it may be occasioned by mechanical violence (as by a penetrating wound of the thorax, or the splintered ends of a broken rib, &c.), or by the accidental extension of disease from adjacent parts. The disease may terminate in resolution and complete recovery; or in adhesion, which often only causes slight embarrassment of breathing; or it may end with such a retraction of one side of the chest as to cause the corresponding lung to become barren or totally useless; or it may cause death either directly by actual suffocation, if the effusion is very copious, and is not removed by tapping, or indirectly, by exhaustion. It is seldom that simple pleurisy proves fatal; but empyema in adults is a less rare event.

In the treatment of pleurisy rest in bed, careful nursing, and light diet are essential. In acute cases in the early stage cupping, leeching, or blistering is generally indicated. When effusion has taken place, purgatives, diuretics, and absorbents should be given. But when fluid is present in large amount and is not diminishing from day to day, it is usually desirable to draw it off by tapping. If the thuid be serous this usually greatly hastens recovery. Even when it is purulent (empyema) aspiration, repeated when necessary, is the best treatment. In the case of children with empyema more especially, in adults, free anti-septic opening and drainage of the cavity alone affords any hope of cure.

**Pleurisy Root.** See Butterfly Weed.

**Pleurodynia** is the name sometimes applied to neuralgia of the chest-wall, which may simulate closely the pain of pleurisy.

**Pleuronecrosis.** See Flat-Fish.

**Pleuronecrosis.** The disease of this name in the human subject is not mentioned at PLEURISY; the following article deals with the disease in cattle so called. Pleuronecrosis Contagi- osa is a contagious febrile disease peculiar to horned cattle, supposed to have originated in central Europe and thence to have been conveyed to all parts of the world. It cannot be certainly traced further back than 1769, when it was known in eastern France as Morie. Not till 1802 was it seen in Germany, 1824 in Russia, 1841 in Great Britain and Ireland, 1843 in the United States, 1853 in Australia, and 1864 in New Zealand. It is a disease which produces a large number of cases, though the system by the lungs, and which, after an incubative period of from two or three weeks to as many months, induces extensive inflammatory exudations in the substance of the lungs and surfaces of the pleura, finally resulting in consolidation of some portions of the lungs, occlusion of the air-tubes, plugging of the blood-vessels, and, generally, adhesion of the pleural surfaces.

It is now clearly demonstrated that pleuro-pneumo- nia never occurs independently of infection, that it is not fostered by overcrowding, exposure, wet, damp, dirty hovels: these influences may predispose an animal to succumb more readily, or, in other words, to become more susceptible, to a disease produced by the specific organism to which undoubtedly the disease is due, as stated by the writer in 1886. He stated that the organism was a micrococci. It has since been discovered that there are three kinds of micrococci—viz. 1st, pneumococcus guttae cerei, whose colony consists of little hard, yellow, or reddish-orange drops of wax; 2d, pneumococcus lichen- oides, which grows in a thin white layer; and 3d, pneumococcus flavescens, whose colonies are elongated or round in shape, and assume a beautiful orange tint. In addition to these cocci a bacillus is found, called by Arling the pneumococulis liquefaciens, and supposed by that observer to be the pathogenic organism causing the disease.

There is much variety in the manifestation of the disease. In some instances, especially during its first stages, it runs a rapid course, destroying life in the course of a few days; in other cases, and these are the most numerous, its onset, course, and termination occupy a period of from two to eight weeks, or even longer; some animals recovering after the shorter periods, whilst others linger and at last die. In either case, the disease is characterized by the presence of an exhausting diarrhoea, imperfect aeration of the blood, hydrothorax or water in the chest, and the depressing influence of degenerated animal materials absorbed into the blood, and anaemia. The more prominent symptoms are slight rigors or shivering, elevation of temperature, an appetite, secretion of milk diminished, an occasional cough is heard which is dry and hard in character, rumination becomes irregular, the bowels rather constipated, and the urine is scanty and high-coloured. In cases that do not begin to recover in this stage the signs of putrefaction increase more or less rapidly; the cough becomes more persistent, the respiratory movements increase in frequency, when the animal stands the elbows are turned out, and whilst recumbent the weight of the body is thrown upon the sternum, the breathing is dyspneic, the diaphragm, in anatomical conformity of this bone, the animal can most readily expand the chest. The breathing is often but not always accompanied by a moan or grunt resembling the bleating of a goat.

Experience has led the great majority of professional men to the conclusion that the disease is not influenced by medicinal remedies; it runs a course. If the dose of the contagium is small, or the animal able to withstand a larger one, it terminates spontaneously in apparent recovery; but an animal which has thus apparently recovered still contains the germs and products of the disease, and remains a source of danger to others for an indefinite period, probably during the remainder of its existence. If, on the other hand, the dose of the specific cause be strong or the animal weak, death follows in cases in which, owing to the anatomical conformity of this bone, the animal can most readily expand the chest. The breathing is often but not always accompanied by a moan or grunt resembling the bleating of a goat.

**Inoculation.**—Experience and successful inoculators have shown the practicability of inoculating with carefully selected lymph—and the non-success of the operation has been proved to be due to a careless selection of the inoculating fluid, and ignorance on the part of the operator—exerts a preservative influence and invests the economy of animals subject to its influence with an immunity which protects them from the contagion during a period not yet determined. Lymph for inoculation should be
removed as soon as possible after the slaughter of an animal not too severely affected with pleuro.

It should be a very light straw colour, the palette the better, and free from all blood and frothy mucus. It is the usual practice to collect the sweat by means of a covered cistern, collected with a porcelain spoon rendered aseptic, and conveyed into vials containing pieces of worsted thread a few inches long, which, as well as the bottles, have been aseptised. One of these worsted threads is inserted, by means of a needle made for the purpose, under the skin of the tip of the tail of each animal. Incision is practised to an enormous extent in Australia, many stock-owners there now believing that but for this it would be impossible to rear cattle successfully.

Plevna, a town of Bulgaria, 19 miles S. of the Danube that this KY. of Sofia, all with a 14,574 by 1834. Here in 1877, Osman Pasha, the Turkish general, after defeating the Russians in several engagements, entrenched himself against their reinforced and superior numbers early in September, and repulsed their advances to take the place by storm by giving an unsuccessful attempt to cut his way through the investing Russian army, he was compelled, provisions and ammunition running short, to capitulate (10th December) with 42,000 men and 77 guns. The siege cost the Russians 55,000 men, the Romanians 10,000, the Turks 30,000. See W. V. Herdber, The Defence of Plevna (1895).

Pleximeter. See Percussion.

Pleyel, Ignaz Joseph, born 1st June 1757 at Ruppersthal, near Vienna, studied under Haydn and in Italy, and in 1783 was made Kapellmeister of Strasbourg Cathedral. In 1791 he visited London, and he harmonised many of Thomson’s songs. See Thomson’s Collection of Scottish Songs. At Strasbourg, during the French Revolution, he barely escaped with his life as a royalist. In 1793 he opened a large music shop in Paris, and in 1807 joined thereto a phonoforte manufactory. He died in Paris, 14th November 1831. His compositions consisted of quartets, concertos, and sonatas.

Plea Polonica is the name given to a disease of the scalp, in which the hairs become matted together by an adhesive and often fetid secretion, and which is especially prevalent in Poland, although it occasionally occurs in other countries. It appears to be of very long standing, to be infested with a fungus of the genus Trichophyton. The only treatment that is beneficial is the removal of the hair, and strict attention to cleanliness; but, as it is popularly believed in Poland, some portion of the hair on the head by way of all other sickness and misfortune, it is often difficult to persuade patients to have recourse to these means.

Plimsoll, Samuel, ‘the sailors’ friend,’ was born at Bristol on 10th February 1824. In his seventeenth year he became clerk in a Sheffield brewery, rose and to a position of trust in the firm. In 1834 he started business on his own account, in the coal trade, in London. Shortly afterwards he began to interest himself in the sailors of the mercantile marine, and the dangers to which they were exposed. He accumulated a mass of facts proving that the gravest evils resulted from the wilful employment of unseaworthy ships, from overloading them, and under-manning them, from bad stowage, and from over-insurance; unscrupulous owners insured rotten or ‘colli’ ships at a value greatly in excess of their real value, trusting the mortgagees to sell them to sea, hoping they would found, by which means they would make bigger profits than they could make by legitimate carrying of merchandise. Failing to induce parliament to take legislative steps to put an end to these evils, Mr Plimsoll himself entered parliament, for Derby, in 1868; but it was not until he had published Our Seamen (1873) and had made an appeal to the general public that he succeeded in getting passed the Merchant Shipping Act in 1878, to ensure temporary measures passed during three preceding sessions. By this act the Board of Trade was empowered to detain, either for survey or permanently, any vessel deemed unsafe, either on account of defective hull, machinery, or equipment, or improper loading, or overloading, or unsound rigging or nationality not entitled to British registry, and inquired by any owner who should ship a cargo of grain in bulk exceeding two-thirds of the entire cargo, grain in bulk being especially liable to shift on the voyage; the amount of timber that might be carried as deck cargo was defined, and enforced by penalties; finally, every owner was ordered to mark (often called the ‘Plimsoll Mark’) upon the sides of his ships, amidships, a circular disc, 12 inches in diameter, with a horizontal line 18 inches long drawn through its centre, this line and the centre of the disc to mark the maximum load-line—i.e. the line down to which the vessel might be loaded, in salt water. Failure to comply with this last regulation exposed the owner to a fine not exceeding £100 for each offence. In 1890 this act was amended, the fixing of the load-line being carried out by a nominated board and made a duty of the Board of Trade. Mr Plimsoll retired from parliamentary life in 1880. But he did not slacken his efforts to make the sailors’ calling safer: in 1890 he published a work on Cattle-ships, exposing the cruelties and great dangers connected with the shipping of live cattle across the ocean to British ports. He died 3d June 1893. See Japp, Good Men and True (1890).

Platinin, or Pliny Latimus, a large mountain-mass (2469 feet) of Wales with three summits, on the boundary between Montgomery and Cardigan, 16 miles W. of Llandinillo. The name is said to be a corruption of a Celtic word signifying Five Rivers, five rivers having their sources on its slopes; one is the Severn, another the Wye.

Plinth, the square member at the bottom of the base of a Column (q.v.). Also the plain projecting band forming a base of a wall.

Pliny (Gaius Plinius Secundus), called the Elder, to distinguish him from his nephew, came of a North Italian family and was born in the Comum (Come), where he was born 23 A.D. He claimed to be a compatriot of Catullus, but the reference is too vague to warrant the assumption that their common birthplace was Verona. His education was carried on in Rome, under every advantage of wealth and family connection, till, when about twenty-three years old, he entered the army, serving on the staff of L. Pontinus Secundus, then conducting a campaign in Germany. He became colonel of his regiment (a cavalry one), and while attending enough to his military duties to make a special study of the throwing of missiles from horseback, on which he wrote a treatise (De Jaculatione Equestri), and to compile a history (afterwards published in twenty books) of the Germanic wars, he gratified his thirst for miscellaneous knowledge by a series of scientific tours, investigating the region between the Ems, the Elbe, and the Weser, and the sources of the Danube. Returning to Rome in 52 with Pomponius, he studied for the bar, at which he practised just long enough to satisfy himself that his true vocation was not in the legal order. Accordingly he withdrew to his native Come, and there, during the greater part of Nero’s reign, devoted himself to reading and authorship encyclopedic in their range. Apparently for the guidance of his nephew he wrote in three books his Studii, a treatise defining the culture necessary
PLINY

for the orator before entering on his career, and also for his nephew the grammatical work, *Dubius Sermo*, in eight books. About the close of Nero's life he was appointed procurator (collector of the imperial revenues) in Spain, where in 71 he heard of his brother-in-law's death, by which he became guardian of his sister. In the spring of the following year, when he returned to Rome, two years after, he adopted Vespasian, by this time emperor, whom he had known in the German campaign, was henceforth his most intimate friend, but court favour did not wean him from study, and so we find him bringing land or water his secretary with book and tablet, the history of Rome, by Aurelius Bassus. A model student, amid metropolitan distraction, he began work by candle-light, in autumn before the day was spent, and in winter by 1 or 2 A.M. Ere dawn he would wait on the emperor and discharge the imperial commissions imposed on him, after which he returned home once more to his books. A slight repast intervening, he resumed work, in summer lying in the sunshine while he took notes or extracts from what was read to him. True to his maxim that no book was beneficial that did not benefit him; if it did not benefit him, he seized every opportunity of jotting down all that interested him either as reader or auditor. A cold bath, followed by a slender meal and a brief siesta, preceded the next spell of work, at which he continued till cena, the Roman dinner, at 3 p.m. Even then he listened to the reading of some book, on which he commented. Such was his life when at court; but at his country seat his studies were uninterrupted—an attendant reading to him even in the bath, or writing to his dictation while he was under the auspicium or anointer (ailiptas). On his journeys by land or water his secretary with book and tablets was always at hand. By this lifelong application he amassed materials enough to fill the 100 volumes of manuscript written very small on both sides which, after using them for his *Historia Naturalis* (published 77), he bequeathed to his nephew. His life, uneventful and studious, was quite dramatic in its ending. In 79 he was in command of the Roman fleet stationed off Misenum when the great eruption of Vesuvius was at its height. Eager to witness the phenomenon as closely as possible, he landed at Stabiae (Castellamare) barefoot and naked, and not without some repugnance when his frame, corpulent and asthmatic as his nephew tells us, succumbed to the stifling vapours rolling down the hill.

His *Historia Naturalis* alone of his many writings survives. Under that title the ancients classified everything of natural or non-artificial origin—not only botany, zoology, and mineralogy, but geography, meteorology, and astronomy. Pliny, however, extends even this elastic definition, and adds to his work by digressions on human institutions and inventions, devoting two books to valuable, if not of fine art. He dedicates the whole to Titus, in a turgid, ill-composed epistle, the low literary level of which is maintained throughout. Nor is his inartistic, sometimes obscure, style redeemed by much scientific faculty in handling his theme. He did not pretend to original research, but the philosophical method which sometimes distinguishes the mere compiler is equally foreign to his pages. His observations, made at second-hand, are presented with no discrimination between the true and the manifestly false, the demonstrable and the simply marvellous. He can even be convicted of having misunderstood the authorities on whom he relies. But with every deduction made from it as to matter and form, his compilation is a praiseworthy monument of reading at once extensive and minute, and supplies us with information on an immense variety of subjects as to which, but for him, we should have remained in the dark.

The most convenient text for the student is that of Jan and Mayhoff (6 vols. Leip. 1857-75), which embodies the best results of these recensions by Silling and Detieffsen. The *Chrestomathia Pliniana* (Berlin, 1857) of the great archaeologist Uriahs is particularly valuable on his comments on fine art; while of translations the soundest and most readable is that of Littre, in French, published along with the original Latin (Paris, 1848-50).

Pliny (Gaius Plinius Cæcilius Secundus), the Younger, was born at Novum Comum, 62 A.D. His elevation to the Senate, in thirty-five, was the result of his paternal uncle's death, was conducted under the eye of his mother, Plinia, of his tutor Virginius Rufus, of whose worth, intellectual and moral, he has left a beautiful memorial, and of his uncle who adopted him. He early displayed high literary aptitude, wrote a Greek tragedy in his fourteenth year, and made such progress under Quintillian that, like his friend Tacitus, he became noted as one of the most accomplished men of his time. His proficiency as an orator enabled him, when not more than eighteen, to plead in the Forum, and brought him much praise. He was made a leg of the praetorian guard in will-cases, but also before the senate. Official appointments came to him in quick succession. Then, still young, he served as military tribune in Syria, where he frequented the schools of the Stoic Euphrates, and of Artemidorus; at twenty-five, the earliest possible age, he was quaestor Caesar's then prefect, and afterwards consul in 100 A.D., in which year he wrote his laboured panegyric of the Emperor Trajan. In 103 he became pro- prefect of the Provincia Pontica, but vacated the post in two years, and, among other offices, held that of curator rei publicae, from which he declined only to satisfy his intellectual wants, and on the occasion of floods. He married twice: his second wife, Calpurnia, granddaughter of Calpurnius Fabius, is fondly referred to in one of his most charming letters for the many gifts and accomplishments with which she sweetened his rather invalid life. He died without issue, but in what year is unknown.

It is to his letters that Pliny owes his assured place in literature as one of the masters of the epistolary style. An avowed imitator of Cicero, he has caught much of the charm of his model, while his Latinity is hardly, if at all, inferior in purity and grace. His letters are noted for their generally fuller than his expression, and, reading between the lines, we discern the features of a truly lovable man, quite aware of his strong as of his weak points, much given to hospitality, and always pleased to help a less-favoured brother, such as Suetonius or Martial. We derive from him not a few of our distinctest impressions of the public and private life of the upper class in the 1st century; above all, it is from his correspondence with Trajan that we get our clearest knowledge of how even the most enlightened of the Romans regarded the then obscure sect of the Christians. It appears that a person acknowledging himself a Christian was liable to punishment, even to death. When under examination, however, no Christian would admit anything further than his practice of meeting together for prayer and his co-religionists. He was questioned on the day before it was light; singing a hymn to Christ as God ('or 'as to a God'—quasi deo); and taking an oath which bound him to no crime, but never to commit theft, robbery, adultery, and malfeasance, and never to deny a deposit. Even when put to torture he remained true to his faith. His deaconesses, confessed nothing more to Pliny, who thereupon consulted the emperor as to how he might put the stop of what he could only call 'a depraved and extravagant superstition.' Trajan declined to lay down a general rule for dealing with the Christians; he recommended that they should
not be sought out on suspicion, but that, if accused and convicted of holding that faith, they should be punished. Accusations unsupported by an accuser were not to be received, while suspected cases were to have an opportunity of clearing themselves by offering prayers to the Roman gods (dis nostris).

Keil's text of the Epistles and Panegyricus (Leip. 1853) is the best, while a useful selection with a good commentary has been published by Church and Brodrrib (1858). The whole is difficult and excellently readable; Orrery's, of the Epistles (1751), is still esteemed.

Pliocene System. Strata belonging to this system are restricted in Britain to a limited area in Essex, Suffolks, and Norfolk; but a few isolated patches occur also in Cornwall and Kent. They consist of irregular lenticular beds of sands and shelly gravels, &c., which never occur altogether in one place. The whole series probably does not exceed 120 feet in thickness, and comprises the following groups arranged in descending order:

CUMBERLAND BEDS: fresh-water or marine sands, clays, and sands, with layers of peat; 10 to 70 feet thick. The fossils are land and fresh-water molluscs, many land-plants, and numerous mammalia.

CHILDEBROOK BEDS: sands and clays; 6 to 10 feet thick; contain marine shells, some two-thirds of which are existing species. Norwich CRAG: fluviatile-marine gravel, sand, and loam; 5 to 10 feet thick. Fossils, chiefly marine molluscs; several land and fresh-water molluscs, and numerous mammals. Hence the name of 'mammaliferous crag' sometimes applied to this group. Of the shells 85 per cent. are living species—1 per cent. beach-shore forms.

Rye CRAG: red ferruginous shelly sand, 25 feet thick, but local and insignificant. 90 per cent. of the numerous shells occurring in this deposit are existing species—10 to 7 per cent. being northern forms.

LANSHAM BEDS: sands, &c., 'occupying pipes' or hollows in the chalk of the North Downs, some 600 feet above the sea.

St. Ethel BEds: clays and gravels, near St. Ethel, Cornwall; contain shells, being of marine origin.

WHITE OR CORALLINE CRAG: shelly sands and clays; fossils abundant; 84 per cent. of the shells are living species, and of these 69 per cent. are northern forms. Polyzoa (popularly called corals) are numerous, hence the name sometimes applied to this group.

On the Continent Pliocene marine deposits are met with in various countries, usually in maritime regions. Most of the evidence of the deposit in the Cotentin, Morbihan, and Aquitaine. But it is in the Mediterranean basin that this system attains its greatest development. Thus, at various points along the coast of the Alps in North Italy Pliocene beds have been found comprising Mollusca. On the northern shores of the Mediterranean, and especially in the south, there are many abundant formations which co-existed with the Miocene fauna and which have an extinct fauna. In the Pliocene of Italy, however, continued submerged—the sea extending through the Alar-Casian depression into Asia. One of the most notable events of the Pliocene was the birth of Etne, Vesuvius, and the now extinct volcanoes of Central Italy. In early Pliocene times the climate was mild and genial, but the conditions became less so during the closing stages of the period. This change is evidenced particularly by the increasing number of northern molluscs and the occurrence of ice-rafted erratics in the English Channel.

Pliosaurus. See Plesiosaurus.

Ploc (Ger. Plock), a town of Russian Poland, on the right bank of the Vistula, 60 miles NW. of Warsaw. Its principal building is the cathedral, built in the 11th century. One of the oldest towns in Poland, Plock was the capital of ancient Masovia, and was severely ravaged by the heathen Swedes. Pop. (1838) 20,660, including many Jews.

Plolischti, or Ploesti, a town of Roumania, 37 miles by rail N. of Bucharest, with petroleum-refineries and a large trade in wool. Pop. 33,651.

Pombières, a spa in the French department of Vosges, 14 miles S. of Épinal, sprang into fashion through the favour of Napoleon III., though the virtues of its waters were known ever
since the times of the Romans. There are nearly thirty springs, ranging in temperature from 66° to 150° F.; their waters are helpful against skin diseases, gout, rheumatism, dyspepsia, female complaints, &c. A handsome casino was opened in 1876, and there are picturesque walks and a park in the valley in which the village stands. Pop. 1971.

Plotinus, the most original and important philosopher of the Neoplatonic school, was born at Lyceopolis in Egypt in 205 A.D., and studied philosophy under Ammonius Saccas. In 262 he joined Gordian's expedition to India in order to study the philosophy of India and Persia; but the emperor being murdered in Mesopotamia, he returned hurriedly to Antioch, whence, in 244, he went to Rome. His lectures here were attended not only by crowds of eager youths, but men and women of the highest circles flocked to hear him. Not only Neopythagorean and Neoplatonic wisdom, but asceticism and the charm of a purely contemplative life were the themes on which he, in ever new variations, and with an extraordinary depth and brilliancy, held forth; and such was the impressiveness of his earnestness made upon his hearers that some of them really gave up their fortune to the poor, set their slaves free, and devoted themselves to a life of study and ascetic piety. It is hardly surprising to find that his contemporaries coupled with his rare virtues the gift of working miracles. Sixty years old, he thought of resigning Plato's 'Republic,' by founding an aristocratical and communistic commonwealth; and the Emperor Gallienus was ready to grant a site in Campania for his 'Platonopolis;' but he died near Muntinore in 270. Although he began to think very late in life, he wrote fifty-four books of very different size and contents to the editorial care of his pupil Porphyry, who arranged them in six principal divisions, each subdivided again into nine books or Enneads.

Plotinus' system was based chiefly on Plato's, combined with Neopythagoreanism and the oriental theory of Emanation—i.e. the constant transmission of powers from the Absolute to the Creation, through several agencies, the first of which is 'Pure Intelligence,' whence flows the Soul of the World, whence, again, the souls of 'men' and 'animals,' and finally, 'matter' itself. Men belong to two worlds, that of the senses and that of Pure Intelligence. It depends upon ourselves, however, to which of the two worlds we direct our thoughts most and belong to finally. The ordinary virtues, as justice, moderation, value, and the like, are only the beginning and very first preparation for our elevation into the spiritual realm; purification is a further step, to which we attain partly through mathematics and dialectic; and the abandonment of all earthly interests for those of intellectual meditation is the nearest approach to the goal. The higher our soul rises in this, the deeper it sinks into the ocean of the good and the pure, until at last its union with God is complete, and it is no longer thought but vision and the ecstasy which pervades it. These are a few snatches of Plotinus' philosophical rhapsodies, to which may be added his mysterious belief in a kind of metempsychosis, by which souls not sufficiently purified during life return after death, and inhabit, according to their bent, men, animals, and even plants. He further held somewhat fantastic views as to gods and demons, and professed faith in astrology and magic. His was the last attempt by the ancient world to solve the great problems not by ratiocination, but through introspective mysticism; and his mode of thought had very unmistakable influence on early Christian philosophy, modern theosophy, and various German Idealistic systems.

See NEOPATONISM and works there cited, and works on Plotinus by Kierchner (1854), Ihnen, and Kleist (1884).

Plots must be distinguished on the one hand from Assassinations (q.v.) and on the other from Rebellions (q.v.). They involve the elements of secrecy and conspiracy, but have not always political assassination for their object, nor do those who carry them through, or attempt to do so, put arms in the hands of a great number of men. The subjoined list only professes to give a selection of the more noteworthy plots of history, intended to supplement the lists given under ASSASsINATION and REBELLION. Details of most of them will be found under separate articles.

Bulgaria, 1884.

Plough. The first in order and importance of agricultural operations is the breaking up of the soil, and the implement employed most largely for this purpose is the plough. The general form of the plough is known to every one, and to the unobservant eye it appears to be a very simple and even primitive tool; nevertheless, much mechanical skill and ingenuity have been expended in perfectly adapting it to its work. It is a combination of instruments (fig. 1) fastened to a beam,

Fig. 1

GBL; the coulter, K, is an iron knife-blade, for cutting the sod vertically; the share, CFD, which is merely a socket fitted on and not fastened to the body of the plough, has a sharp point, C, and a projecting horizontal edge, CO, on its right-hand side, its part of the work being to separate the under surface of the sod from the subsoil; by means of the mould-board, H, the cutting edge, now wholly separated from the firm ground, is raised up and turned over by the forward motion of the plough;

Fig. 2

and the stile, or handles, one of which, BL, is a continuation of the beam, the other, M, being fastened partly to the former by rods, and partly to the lower portion of the framework (fig. 2), which also shows the point of the plough with the share.
removal), are for the purpose of guiding the implement. The front part of the beam is formed with an upward curve; at its extremity is placed the bridle, N, to which the horses are attached by means of swing-trees and chains or traces, and the object of the curb is to limit the elevation or depression of the horse. The or depress the line of draught, or move it to the right hand or the left, as may be found necessary.

The left sides of the coulter, share, and framework ADEB should evidently be in the same vertical plane. The form of the mould-board is of the utmost importance, and has chiefly attracted the attention of agricultural machinists since the time when improvements on the plough were first projected. Its office being to raise and turn the sod, it is necessary that the surface should slope upwards and outwards from the front, so as to apply a pressure in both directions, and, accordingly, the surface is so shaped that from the point of the share, where it is horizontal, it gradually curves upwards, till, at the extremity, it inclines over away from the body of the plough. The gradual change produced on the position of the furrow-slice is seen in fig. 3, where AEDC on the left-hand side represents the slice untouched by the plough, AD being the line of section by the coulter, DC by the share, BC the open side from which the previous furrow (E) to the right hand side has been separated, and the four successive rectangles, ABCD to the right, illustrate the successive changes of position of the furrow as the mould-board is pushed forward under and on its left side, till it is finally left, as represented in AEDC, on the right hand; E, F, G are furrows which have previously been laid in their proper position. The modern plough is wholly formed of iron, and in nearly all the English and several of the Scotch and Irish made ploughs wheels are attached at or near the front end of the beam, a contrivance which renders the implement more steady in its motion, more easily managed, and capable of doing better work in the hands of an inferior workman. The usual dimensions of the furrow-slice in loam or stony soil are about 8 or 9 inches in breadth by 6 in depth, and in land for green crop 10 or 11 inches in breadth, and 7 to 9 in depth. Shallower ploughing is not infrequently adopted, especially on thin soils, and in various parts of England. Nor is it uncommon to plough staddle-land 10 inches or more in depth.

Other kinds of ploughs are used for special purposes, such as trench-ploughs, which are made on the same principles as the common plough, but larger and stronger, so as to bring up a portion of the subsoil to the surface; subsoil ploughs, some patterns of which have no mould-board, and merely stir and break up the subsoil, thus facilitating drainage; double mould-board ploughs, which are merely common ploughs with a mould-board on each side, and are employed for drilling turnip or potato land, for water-furrowing, and for earthing up potatoes; turn-round ploughs, which have the mould-board so arranged that in going in both directions the furrow is turned to the side; American Chin ploughs, which are exceptionally light in draught, go over the ground rapidly, and break up the surface soil more finely than the ordinary plough; the double-furrow plough, which turns two furrows at one operation, and which, although used on many farms, has not become so popular as was at one time expected. Of all these ploughs there are many varieties, each maker having generally some peculiar views regarding the object and form and proportions of the different parts of the instrument. For those who wish to study minutely the best form of plough it will be necessary to consult works on agriculture and agricultural implements.

The operation of ploughing can only be briefly referred to. Wherever the soil has been sufficiently drained the ridges can be cradled and ploughed on the flat, high ridges being no longer necessary for carrying off the water. It is found in practice that the fewer the open furrows the better, particularly when the land is intended for a grain crop which is to be sown by drill or broadcast with machinery, and when the crop is to be cut with a reaping-machine, as is now almost universally the case. It is curious to notice how one improvement in farm practice leads on to another. The most common mode of ploughing with horses is now simply by casting the soil two ridges in and the next two out, beginning always with the two ridges where last time was left the open furrow.

The process of fearing or commencing a ridge differs according to the state of the land to be turned over. If there exists an old furrow or hollow, as is generally the case in arable land, the two shallow furrows are turned, the one against the other, and so on; along each side of this commencement the plough moves, adding furrow after furrow, and increasing in depth until the third or fourth round is reached. This constitutes what is technically called the gathering system. In newly-cleaned land, or where a hollow does not appear to turn the first furrows into, two furrows are thrown out and then turned lightly in. The most common system, however, is what is known as edging or clearing. That is, after one fearing is accomplished, another is made at the other side of the ridge, and furrow after furrow is turned towards the inside of each of these fearings until the whole ridge is ploughed, and then in the centre is formed the finish or mid—furrow or trench into which the turning is turned the next time the land is ploughed.

The plough is one of the most ancient of implements, and is mentioned in the Old Testament at a very early period, iron shares being also incidentally noticed more than seven centuries B.C. Dr F. R. Taylor has in his admirable clearly shown how the plough arose by gradual development out of the hoe, and that out of the pick or hatchet.

The fields of Sweden were formerly tilled with the 'hack,' of which specimens were still seen in the 19th century. The hack was simply a stake of fir with a broad wooden iron at the lower end cut short and pointed. This implement was gradually made heavier, and dragged by men through the ground, so as to make a simple furrow. Next it was made in two pieces, with
a handle for the ploughman and a pole for the men to drag by, the share was shod with an iron point, and at last a pair of cows or mares were yoked instead of the men. The development of the Egyptian plough was similar. The ancient Egyptian plough was wholly of wood, and in some instances consisted of little more than a pointed stick, which was forced into the ground as it was drawn forward; though there seems to have been ploughs with handles, and with metal socks. The Aryan peoples took pride in their being the ploughing (arara; see Agriculture, Vol. I. p. 88) peoples. The earliest form of the Greek plough, the auto- 

Fig. 5. 
goun (fig. 4, a), is an example of this; it was merely the trunk of a small tree, which had two branches opposite to each other, one branch forming the share and the other the handle, while the trunk formed the pole or beam. The more improved form, the plowton, in use among the Greeks, was not substantially different from the modern form in use in some parts of Asia Minor (fig. 4). The ancient Egyptian plough in one of its early stages is represented in fig. 5. The Romans, an essentially practical nation, largely improved on the plough, adding to it the coulter and mould-board, and occasionally attaching wheels to the beam to prevent the share from going too deep into the earth (fig. 6). The plough was almost unknown among the American aborigines, though Prescott describes a mode of ploughing practised among the Peruvians, which consisted in dragging forward a sharp-pointed stake by six or eight men, its sharp point, which was in front, being kept down in the ground by the pressure of the foot of another man who directed it. The ancient heavy plough dragged by eight oxen was still in use in Aberdeenshire well into the 18th century. In Britain the most important amendments on the plough are not two centuries old, and some of them were doubtless borrowed from the careful agriculture of Holland. England took the lead in improvement, followed some time later by Scot-

Fig. 6. 
goose took out letters-patent for engines and machinery to plough the ground without the aid of oxen or horses, and the attempt has been made to show that steam was the motive power intended to be employed; but, as the first patent was taken out nearly forty years before the Marquis of Worcester described the steam-engine in his Century of Inventions, the grounds for such an opinion do not seem quite satisfactory. In 1769, however, after the steam-engine had been applied to other purposes, there was lodged in the Patent Office the application for a new invention, the object of which was to plough, harrow, and do every other branch of husbandry, without the aid of horses. The patentee was Francis Moore; and so confident was he of the merits of his plan that he sold all his own horses, and persuaded his friends to do the same; because the profits of that noble and useful art will be so affected by the new invention that its value will not be one-fourth of what it is at present. Moore, like many who followed in his wake, was much too sanguine. The truth is that even yet steam-power has only to a very small extent supplantad horse labour in the cultivation of the soil. Early English patentees were Pratt in 1810, and Heathcote in 1832. But the first steam cultivating apparatus which gave anything like satisfac-
tory promise of success was that for which Messrs.
Fiskan of Stamfordham, Newcastle-upon-Tyne,
took out a patent in 1835. Mr Fowler of Leeds,
and Messrs Howard of Bedford, and others
followed with apparatuses of various patterns.
The different inventions brought into notice from
time to time have included plans for engines
travelling over the surface of the ground, drawing
ploughs or other cultivating implements along
with them; engines working on tramways and
drawing implements after them; engines mov-
ing along opposite headlands, and working imple-
ments between them by means of wire-ropes, and
stationary engines driving implements also by
means of wire-ropes. Only two of these systems
got beyond the experimental stage. These are
what are called the direct and round-about—the
former where the pull of the implement is directly
to and from the engine, or between two engines,
one at each end of the furrow; and the latter
where the implement is drawn at right angles.
The best known of the apparatuses now in use are
those made by Fowler, Howard, and Barford
and Perkins, of Peterborough.
The ploughs used in the various systems are very
similar in construction, some taking four and others
six furrows at each time. Fowler’s apparatus is
shown at work in figs. 8 and 9.
It has to be noted, however, that, with all the
ingenuity and capital expended on the perfecting
of the appliances, steam-power has not been employed
in the cultivation of the soil anything like so
advantageously or extensively as was at one time
expected by the advocates of the practice. The
great agricultural depression following the disas-
terous year of 1879 gave the system its first serious
check. The injury unwittingly done to large
extents of land by excessively deep-ploughing—
by burying the good soil and bringing bad material
to the surface—also tended to discredit steam-
cultivation. It has as a rule been found in practice
that moderate ploughing and deep stirring are pre-
ferrable to deep ploughing, and steam-power is now
more largely employed in stirring and harrowing
the soil than in turning it over in furrows. Upon
Fig. 8.—Fowler’s Anchor, Engine, and Plough at work.

extensive farms, where the fields are large and con-
veniently shaped, steam-tillage may be pursued with
excellent results, if the farmer is careful to adapt
the operations to the particular character of the soil.
Steam-tillage, if wisely directed, is more thorough
than tillage by any other power, and the great
speed attainable is also an important consideration,
especially in precarious seasons, when the soil is not
long in a favourable condition for being worked.
See Morton’s Cyclopedia of Agriculture (1856);
Stephens’ Book of the Farm (new ed. by present writer,
1880); and the Book of Farm Implements, by Slicht
and Scott Burn (1859); Professor J. Scott’s Farm Engineer-
ing (1884); and Scott Burn’s Text-book of Farm Engineer-
ing (1885).

Fig. 9.—Fowler’s Plough.

Plough-Monday, or Plow-Monday, the
Monday after Twelfth Day, and termination of the
Christmas holidays, when, according to the old
usage, the plough should be set to work again.
On Plough-Monday ploughmen were wont to drag
a plough from door to door, begging money for
the usual antics and mummeries at the festivity.

Plower, a name given to numerous species of
birds belonging to several genera of the family
Charadriidae. They have a straight compressed
bill, but the upper jaw is slightly inflated and
slightly bent at the point; the nasal groove ex-
tends about two-thirds of the length of the bill, the
necks are longitudi-
nally cleft near the base; the legs, which
are not very long, are
naked a little above
the tibial joint; with
one exception there is
no hind-toe; the wings
are rather long and
pointed, the first quill-
feather is the longest.
The species are numer-
ous, and are found in
every quarter of the

globe; many of them
are birds of passage.
They chiefly frequent
low, moist grounds, where they congregate in
large flocks, and feed on worms, molluscs, in-
sects, &c.; but some of them visit mountain-
ous regions in the breeding season. They fly
with great strength and rapidity, and run with
much swiftness. The flesh and eggs of many
of them are esteemed delicacies. A common
British species is the Golden Plower (Charad-
rius plusialis), a handsome bird, of a blackish
colour, speckled with yellow at the tips and edges
of the feathers; the throat, breast, and belly black
in summer, whitish in winter. The golden plower
is a bird of passage, visiting in summer the
northern parts of Europe, of the west of Asia,
and of North America, and migrating to the
south in winter. It is known in most parts of
Europe, and is common in many districts of
Britain, breeding in the northern counties. Great

Ploughgate, in the law of Scotland, is an
expression denoting a quantity of land of the
extent of 100 acres Scots. See CARCATE.
numbers frequent the sandy pastures and shores of the Hebrides and of the Orkney and Shetland Islands. It makes an artless nest, little more than a slight depression in the ground, and lays four eggs. The parent birds show great anxiety for the protection of their young, and use various stratagems to divert the attention of an enemy. The golden plover exhibits great restlessness on the approach of wet and stormy weather, whence its specific name plumipes. The Ringed Plover (Charadrius hiaticula), locally called Stone-hatch or Sand-lark, a much smaller bird, not uncommon in the more northern parts of Europe, and in Iceland and Greenland. It is grayish brown above, whitish beneath, with a collar of white round the neck, and below it a black—in winter a brown—collar; the head marked with black and white; a white bar on the wing. Very similar, but smaller, and with an incomplete collar, is the Kentish Plover (Pluvialis curvirostris); and also similar in form and habits is the smallest of the British species, the Little Ringed Plover (Pluvialis minutus). Both of these are rare in Britain. The Gray Plover (Squatarola helvetica), a species somewhat larger than the golden plover, is distinguished by the white axillaries, white tail-coverts, and the presence of a hind-toe. North America has a number of species of plovers, such as the Killdeer Plover (Pluvialis vociferus), abundant on the great western prairies, and not unfrequent in the Atlantic states. It utters, when approached by man, a querulous or plaintive cry, like the lapwing, the Green Plover. See DOTTEREL, and LAPWING; and for the so-called Stilt Plover, see STILT.

Plover's eggs are sold in enormous quantities in London and other large towns, and command an extraordinary price, eighteen shillings a dozen or even more, being sometimes given for them, and the cost is seldom less than threepence or sixpence per egg. These are supposed all to be plover's eggs, or, really, lapwing's eggs; but doubtless the eggs of many other birds are substituted, those of the red-shank being very similar in appearance and flavour. Rooke's eggs are too decidedly unlike the plover's to be put in their place. Some sea-birds' eggs are occasionally passed off under the name; and it is said that eggs outwardly unlike plover's have been skillfully painted by linseed in order to deceive. Scotland, Ireland, and Holland are all laid under contribution to produce the tens of thousands of dozens of genuine plover's eggs which it is computed are annually consumed in London.

Plum (Prunus communis or P. domestica), a species of fruit-tree of the natural order Rosaceae.

The plum is so familiar as a fruit in all temperate countries as to need no description here. The Wild Plum, or Blackthorn, or Sloe (q.v.), is common in English hedgerows, thickets, and open woods, and occurs more sparingly in similar places in Scotland. It is grown in Europe generally, and in Russia and central Asia. From the rise all cultivated varieties of the plum are supposed to be derived, but some conjecture that P. spinosa (Bullace, q.v.) and P. spinosa are the parents of some of the types of these varieties. The most reasonable probability is that the original forms of wild plum found in England and in other countries were merely varieties of one species—P. domestica. Other varieties of plum, besides the Sloe, Bullace, and Damson found wild in England, are the Mussel and the Wine Sour, which are used in cooking and in confectionery, and are regarded as primary varieties of the wild plum. The cultivated varieties of the plum are very numerous; there are larger and smaller kinds, but their value in the dessert is reckoned by their sweetness and flavour rather than by their size. Thus, the Green Gage, a kind with only moderately-sized fruit, is the most esteemed of all. It is the Beine Claudia of the French, and the Regina Claudia of the Italians. Magnanis Bomun, a very large white variety, though one of the handsomest, is accounted only of second-rate quality. The uses of the plum for dessert in the making of pies, tarts, preserves, and sweetmeats are familiarly known. Prunes are the dried fruit of certain kinds of plum. The finest of all the French prunes are made at Brignol in Provence of the varieties of plum called Perdriogen blanc and Perdriogen violeta, which are hence named Pruines de Brignol. The manner of converting these plums into prunes is by drying in a slow oven. The fruit is allowed to remain on the tree till it is so ripe that a little shaking would cause it to fall. They are then carefully picked and spread out in the sun on slabs made of lath or wickerwork, till they become soft. Afterwards they are put in a spent oven, and shut up close in it for twenty-four hours, and then taken out. The oven is again heated, somewhat warmer than before, and the plums returned to it till the following day, when they are taken out and turned by slightly shaking the oven. When the oven is reduced rather warmer than before, and the fruit returned to it for twenty-four hours, and so on till the operation of drying is finished, a point which only experience can nicely determine when reached. Other kinds of prunes of inferior quality are made from the fruit of the Petit Damas, and from the Queche, the latter being made in Germany. From this also is distilled a kind of brandy. In Bosnia and Herzegovina nearly 60,000 tons of prunes are produced in a good season. Prunes are nutritious and laxative, and stewed in water are excellent diet in cases of constipation. The manner of converting these plums into prunes is by drying in a slow oven. They impart their laxative quality to the water in which they have been stewed, and thus a pleasant and beneficial decoction may be prepared for those who through impairment of the digestive organs cannot eat the fruit. The plum is grown in orchards as standard and bush trees, or they are in the case of the choicer varieties trained to walls. It is not fastidious as to soil, but the finest fruit is produced on strong but well-drained loam. The superior kinds are propagated by budding or by budding by grafting, the inferior by layers or by cuttings of the roots, the latter being a common method in rearing Damsons in some parts; but the quickest and best method of increasing all is by budding. The wood of the plum-tree is hard and fine-grained, and is used in cabinet-work, in turnery, and for making musical instruments. The Cashmere Plum (P.}
Pluralism

PLURALISM

Bokharensis), cultivated in Cashmire and Bokhara, is regarded as a distinct species. The Cherry Plum, or Myrobalan Plum (P. cerasifera or Myrobalanus), is a bushy shrub, to the sloe, with pendulous globular red fruit. It is a native of North America, but is often cultivated for its fruit on the continent of Europe. In Britain it seldom produces fruit. P. martima is a shrub, indigenous to sandy soils on the seacoast of North America from Massachusetts to Georgia. It has a dark-purple agreeable fruit, about the size of a pigeon's egg. Other native American species are P. chic Micka, the Chick saw Plum, a shrub or small tree of the southern states; P. americana, a bushy tree ranging from Canada to Georgia; and P. glandulosa, of Texas, which is less than a foot high, and has crooked thorny branches.

The Cocoa Plum or lace of the West Indies is the fruit of Chrysobalanus icaco, a tree of the natural order Rosaceae, sub-order Chrysobalanaceae. The fruit resembles a plum, but has a sweet although slightly astringent taste, and is eaten both raw and preserved. The fruit of Parinarium excelsum, another of the Chrysobalanaceae, is called Gray Plum at Sierra Leone. — The term plum is used loosely for the Date Plum (q.v.) and plum or plum-bum was a word once current for £100,000.

Plumage. See Bird, and PLUMER'S PELS.

Plumbago, Plumbaginaceae, a natural order of exogenous plants, herbaceous or half-shrubby, to which belong about 100 known species, chiefly found on the seashore and in the salt marshes of temperate regions. Some are found also in elevated regions in all zones. Many have flowers of great beauty, and are therefore favourites in gardens. Some are occasionally used in medicine as tonics and astringents; others, being exceedingly acrid, as vesicants, particularly species of Plumbago. Thrift, or Sea-pink (q.v.), is the most familiar British example of the order. Statice cotornitana, a native of the United States, and there known by the name 'Marsh Rosemary,' is extremely bitter and astringent, and is used in domestic medicine for niceties of the mouth. Its most abundant principle is tannic acid, of which it contains 12 per cent. Along with this, it gives a resinous and extractive volatile oil, resin, caoutchouc, colouring matter, lignin, and various salts. Sea-lavender (Statice Linumita) — an inhabitant of the coasts of England, generally, but rather rarely so, of the Scottish coasts, contains several species of the western coasts of Europe, the Mediterranean, and western Asia, appearing also on the seashore of South America and of the Carolinas — has the same qualities as the preceding.

Plumago. See BLACK LEAD.

Plumier-work. See BUILDING, SANITATION, SEWAGE, WATER-SUPPLY.

Plumec-bird, a term sometimes given to the Euphineche or Long-tailed Birds of Paradise (q.v.).

Plummer's Pills. See GUAIACUM.

Plumtree. Edward Hayes, was born in London, August 6, 1821, and educated privately and at University College, Oxford, graduating with a double first-class in 1844. The same year he was elected fellow of Brasenose College. He became chaplain at King's College, London, in 1847, and afterwards professor of New Testament Exegesis there. In 1863 he was given a prebend of St. Savin's in 1875 to 1878, he was principal of Queen's College, Harley Street. He was selected preacher at both universities, Boyle Lecturer in 1860-67, and one of the Old Testament Company for the Revision of the Bible. In 1869 he was presented to the rectory of Pluckley in Kent, which four years after he exchanged for the vicarage of Bickley, and in 1881 he was installed Dean of Wells. He received the D.D. degree from Glasgow in 1876. He died after a short illness, February 1, 1891. Of his numerous contributions to theology many may be found in his Boyle Lectures, Christ and Christianity (1867), Biblical Studies (1870), Exposition of the Epistles to the Seven Churches of Asia (1877), Introduction to the New Testament (1883), and The Spirits in Prison (1883), in which he spoke out eloquently his belief in the Wider Hope and an Intermediate State of Probation. He contributed Proverbs to the Speaker's Commentary; Matthew, Mark, Luke, Acts, and 2 Corinthians to Bishop Ellicott's New Testament Commentary for English Readers, as well as Isaiah, Jeremiah, and Lamentations to the same editor's Old Testament Commentary; Ecclesiastes, James, 1 and 2 Peter, and Jude to the Cambridge Bible for Schools; and 1 and 2 Timothy to Dr. Schaff's Popular Commentary on the New Testament. Besides these, his contributions to Smith's Dictionaries and the theological and literary journals were numberless.

Dean Plumtre's name is also widely known by his admirable verse translations of Sophocles (1865), AESCHYLV (1868), and the Commedia of Dante in the metres of the original (1886); as well as by several volumes of original verse, including Launces (1864), Master and Scholar (1866), and Things New and Old (1884). His Life and Letters of Bishop Ken (1886) is less happy.

Plum-pudding. This national English dish is an example of the happy results of the law of survival. The plum-pudding which brightens our ancestors has been drained and dried and squeezed into the moulds of civilization, and few will doubt the 'survival of the fittest' among its ingredients. It is not known when the change from porridge to pudding actually took place. In Hudibras we find a mention of 'minced pies and plum-porridge.' Addison in the Tatler speaks of both as the 'first parts of the dinner;' and in the Spectator, No. 260, plum-porridge is mentioned as eaten on Christmas Day. Southey in his Omnium, vol. i. p. 7, quotes a recipe for plum-pudding given by Chevalier d'Arvieux, who in 1658 made a voyage in an English forty-gun ship. This pudding was directed to be boiled in meat broth, and when mashed up to be covered with grated cheese. In later recipes we find nothing of the kind, unless a hint of plum-porridge be discerned in the mixture called Baue, a posset of raisins of corans with'sweet wyne' and 'crustes of bred.' A recipe for this is given in A Noble Book of Cookery (ed. Napier, p. 109), which must have been written out in the 15th century, but was then probably copied from one of a much earlier date. For a modern recipe the following may be taken: 

Plum-pudding — 1/2 lb. beef suet, 1/2 lb. raisins, 1/4 lb. currants, 1/4 lb. mixed peel, 1/4 lb. bread-crumbs, 1/4 lb. sultanas, 1/2 lb. mixed peel, 1/4 lb. brown sugar, four eggs, one pint of milk, orange slices, and four dozen of brandy, two oz. almonds, half a nutmeg, a little salt. Chop the suet finely, stone the raisins, clean and pick the currants, blanch and chop the almonds, cut the candied peel in thin shreds. Mix all very well together, turn into a well-greased basin, cover with a cloth, and boil for four hours, or, better, steam for twelve hours. Serve with brandy or sweet sauce.

Plumstead. See ERITH.

Plumularia, a genus of Hydrozoa (q.v.) belonging to the division Hydroidea.

Plumule. See SEED.

Pluralism, the holding of more than one office at the same time. Persons in power have often
added to their wealth and consequence by holding several appointments; but such pluralism is forbidden by the constitutional practice of many modern states. In England a minister who holds two political offices (e.g. those of First Lord of the Treasury and Chancellor of the Exchequer) is only half the salary of the second. Pluralism in the church has been held unlawful from the earliest times, and is forbidden by many ancient councils, as Chalcedon (451 A.D.), 24 Nicea (787 A.D.). This prohibition, however, was not regarded as absolute; canonists distinguish between 'compatible' and 'incompatible' benefices or dignities. Two benefices may be incompatible in three ways—(1) if each requires residence; (2) if the duties of both fall to be discharged at one and the same time; or (3) if the revenue of either fully suffices for the living of the incumbent. In other cases benefices or dignities are considered compatible, and with the due dispensation, granted by the pope, may be held by the same person. In England the law of the church has been made more stringent by acts of parliament passed in 1851, 1861, etc., the effect of which is to be that no person can now hold two benefices unless the churches are within two miles of each other and one of them is not worth more than £200 a year. A benefice of 3,000 population is not to be held along with a benefice of 500 population. In other words, if two benefices benefit a clergyman must obtain a dispensation from the Archbishop of Canterbury, and on applying for the dispensation he must forward to his bishop a full statement of particulars in regard to the two cases. Acceptance of a second preferment, except in the cases provided for in the acts, will vacate any preferment previously held. The practice of granting livings to be held in commendam with a bishopric has been abolished. In Scotland it is contrary to the old Scotch statute of 1381 for a minister of the Established Church to hold two or more charges, and the rule has been regularly enforced in the case of two pastoral charges. The question has, however, sometimes arisen with reference to clergymen appointed professors before or after an appointment to a pastoral charge, in which case a resigning president of one college will resign at a certain time after the appointment. Non-established churches, in Great Britain and elsewhere, are guided by the rules of their respective constitutions. See, for England, Cripps, Lives of the Church and Clergy; and for Scotland, Duncan, Parochial Laws.

Plush (Fr. peluche), a variety of cloth woven like silk, from having a longer and more open pile. Formerly this pile was of goat's hair or worsted, but now it is largely made of silk, with a cotton backing, and sometimes the whole fabric is of silk. Silk plush is the material used for the outside of gentlemen's 'silk hats', and for the surface of chenille plush. Chenille also works in coloured silks for articles of ladies' attire and for covering furniture; but plush is used par excellence for lively knee-breeches.

Plutarch (Plountarchos), a prolific writer of the Gracco-Roman period, was born about 46 A.D. at Chaeronea in Boeotia, where his family was one of good standing. Nothing is known of his personal history but what may be gathered from his own writings. His life was commenced at Athens under the academic philosopher Ammonius in 66, the year of the Emperor Nero's progress through Greece. He paid more than one visit to Rome, the then metropolis of the world—on the first occasion in the reign of Augustus as chargé d'affaires of his native town. There he enjoyed the friendship of several men of mark, such as Gaius Sosianus Scenio, who was four times consul, while he devoted himself to a course of study and gave public lectures in philosophy, so that he had but little leisure left for learning the Latin language, and never attained a full knowledge of it. Nevertheless his Latin is remarkably correct, and sound, and free from the idiosyncracies of Roman institutions. The story that he became Trajan's preceptor, and was raised by that emperor to the consulship is a legend of doubtful credit.

Life at Rome, however, was not altogether to his taste; he preferred the quiet of his native place, and the delights of private life muting his taste about 120, discharging the civil and religious duties which fell to his station, liberally disbursing his stores of learning, and offering himself as a sort of spiritual guide and physician of the soul to those who needed moral hygiene and desired to rule their lives by some higher standard in a corrupt and effete age, when the old faiths were dead and the objects of modern life as yet below the horizon.

The extant writings of Plutarch fall into two principal classes—(a) his historical works, (b) those which are grouped under the general head of Parallel Lives—the work by which he is best known. These contain a gallery of portraits of the great characters of the ages preceding his own. They were published in successive books, each pair forming one book (biblion), a Greek and Roman being usually selected to represent the respective careers, being chosen for the subject of each. The forty-six extant Lives were contained in twenty-two books, probably in the following sequence (that in which they are usually arranged being purely arbitrary): (2) Sertorius—Eumenus, (3) Cato—Mnemon, (4) Theocritus—Quintus Ennius, (5) Demosthenes—Cicero, (6) Agis and Cleomenes—Grecechi, (7) Pelopidas—Marcellus, (8) Phocion—Cato, (9) Aristides—Cato major, (10) Pericles—Publius Maccius, (11) Nicias—Crassus, (12) Dion—Brutus, (13) Timon—Anullius Paulus, (14) Thukydides—Titus Flaminius, (15) Thrasicles—Camillus, (16) Alexander—Cesar, (17) Agesilaus—Pompeius, (18) Pyrrhus—Marinus, (19) Solon—Valerius Publicola, (20) Demetrius—Antoninus, (21) Auletes—Coriolanus, (22) Theseus—Romulus, (23) Charon—Hannibal, (24) Theseus—Hannibal, a series, which includes (2) to (9), was written at the suggestion of some personal friends. The biographies in this series partake more of a historical than of an ethical character. The second, (10) to (15), was composed for the writer's own satisfaction and to excite improvement; the third, (20) and (21), and (22) to (24), delivered with prehistoric characters. The single biographies of Aratus, Artaxerxes, Galba, and Otto do not come under the category of Parallel Lives. The sequels which come after most of the Lives, giving a detailed comparison (synkrisis) of each warrior, statesman, legislator, or hero, as the case may be, and of the exact points of resemblance between them, hardly accord with the design of Plutarch, and are therefore regarded as spurious by some critics.

Plutarch's Biographies are not merely popular compilations, but monuments of great literary value for the precious materials which they contain, based as they are upon lost records. The author adheres throughout to his professional maxim of 'neuter eduction' or education was commenced or briefly touches upon the most famous actions or events which distinguish the career of each subject of his biography, holding that these do not show a man's virtues or failings so well as some thrilling incident, word, or jest. C'est là vérité morale,' says Grégoire, 'un vrai historique, qu'il poursuit; l'âne n'est pour lui que
PLUTARCH

le nœvra, l'autre est le but.' For this reason the Parallel Lives are and will remain the book of all ages, for no book of classical antiquity has had more influence upon the leading men of the world, so that Plutarch may almost be called the interpreter of Greece and Rome to modern Europe. They form indeed a complement to the earlier and less moral Plutarch, and the Moralia—a collection of short treatises, sixty or more (though certainly not all from Plutarch's hand), upon various subjects—Ethics, Politics, History, Heathen, Love-stories, and Philosophy. The last comprise discussions of the nature of the world and spiritual beings, On the creation and government of the Universe, On the human soul, and similar speculations, classed by the ancients under the head of Theosophy. 'The treatise upon Isis and Osiris in this series,' says its most recent translator, Mr. C. W. King, 'is the only complete account of the religion of Egypt that has come down to us—written too by one who had been initiated in its deepest mysteries. The three treatises upon the Oracle also are of the highest value, and that on Superstition is one of the most eloquent and clearly written, since it is Professor of the essays, especially those on Brotherly Love, On gradual advance in virtue, On the benefit to be got out of enemies, breathe quite a Christian spirit, although the writer probably never heard of Christianity or of that part of the divine function of the man: 'For the apparent delays in divine justice; another, On the conduct proper to young men at Lectures, which is partly moral, partly social in its tone. The nine books of his Symposium or Table-talk on a variety of topics exist in the hands of the most amiable and genial of boon companions, who appreciated good conversation; while his dialogue Gryllus reveals a remarkable sense of humour.

Though not a profound thinker, Plutarch was a man of rare gifts, and occupies quite a unique place in literature as the encyclopedist of antiquity. He was not master of any science, but whatever was noticeable in natural, moral, or metaphysical science did not come amiss to him, and he had a universal sympathy with genius and nobility of character. As a writer he is burdened with his contemporaries. His name does not even figure in the list of those who have written on the subject of his Dialogues. His Moralia are, in fact, an encyclopaedia of all that was known of the myths and legends of Greece and Rome. His style is free, graceful, and poetical, and he is master of all the forms in which the ancients wrote. His works are those of J. J. Reiske (12 vols. 1742–79) and Dümmler-Döhrer in Didot's Bibliothèque (5 vols. 1846–55). The best text of the Lives is that of Sinentius in the Teubner series (5 vols. 1874–81) of the Moralia, that of Dümmler (12 vols. Oxford, 1790–1803; unfinished), and that in the Teubner series by G. N. Bernardakis (6 vols. published in 1898–99). Separate annotated editions of the Lives have been published by Held, Leopold, Siefert-Blass, Sinentius-Fuhl in Germany, and in England by the present writer, with elaborate commentaries (Sulla, Demosthenes, Greece, Nicias, Timoleon, and Themistocles), and by E. G. Hardy (Galba and Otho). There are translations of the Lives in English by the brothers Langhorne and De Bryden (the latter in the Clough, 5 vols. 1854) neither so scholar-like and correct as the French of Jacques Amoyt (Paris, 1559), from which Sir Thomas North's version (1579; new ed. by W. North and J. Strype, 1727) is a faithful rendering of the Latin text of each separate Life. The best translation of the Moralia is that by several hands, corrected and revised by W. W. Goodwin (Boston, U.S., 1874–78).

Pluto (Gr. Plouton, from ploutos, 'to be rich'), originally only a surname of Hades, as the giver of wealth, is, in the Greek religion, the third son of Cronos and Rhea, and the brother of Zeus and Poseidon. On the tripartite division of the universe he obtained the sovereignty of the under-world—the realm of darkness and ghostly shades, where he is enthroned as a 'subterranean' god, a moralist and ruler of the subterranean, and the spirit of the dead. His dwelling-place, however, is not far from the surface of the earth. Pluto is inexorable in disposition, not to be moved either by prayers or flatteries. He is borne on a car, drawn by four bulls. He is clad in a robe of blue and golden reins. His helmet makes him invisible. According to some scholars, his name of Hades is from a priv. and ideia, 'to see;' although others, with less probability, derive Hades from hadô or hadô, 'I receive or embrace,' and translate the word the 'regarder.' In Homer, Hades never means a place, but always a person. Moreover, it is to be noticed that the poet does not divide the realm of the shades into two separate regions. All the souls of the dead—good and bad alike—mingled together. Subsequently, however, when the ethical conception of retribution became more widely developed, the kingdom of the dead was divided into Elysium (q.v.), the abode of the good, and Tartarus (q.v.), the place of the wicked. This change also exercised an important influence on the conception of Pluto. The ruler of the underworld was not only acquired additional power and majesty, but the very idea of his character was essentially modified. He was now regarded as a beneficent deity, who held the keys of the earth in his hand, and possessed the power of life and death. Hence his epithet in Greek, Pluto or Ploutos, and who blessed the year with fruits, for out of the darkness underground come all the riches and swelling fullness of the soil. Hence, in later times, mortals prayed to him before proceeding to dig for the wealth hidden in the bowels of the earth. Plato married Persephone (Proserpina), the daughter of Demeter (Ceres), after carrying her off from the plains of Enna. He assisted his brothers—according to the mythological story—in their wars against the Titans, and received from the Cyclopes, as a reward for delivering them from Tartarus, the helmet that makes him invisible, which he lent to Hermes (Mercury) in the aforesaid war, to Perses in his combat with the Gorgons, and which ultimately came to Meriones. The Erinyes and Charon obey his behests. He sits in judgment on the open and secret act, and is assisted by three subordinate judges, Ἀκώς, Μίνως, and Ὀδυσσείας. At Ellis alone was there a formal cult of Pluto, though in many places in Greece he was worshipped constantly with Demeter and Kore. In the groves where the flowers the cypress, boxwood, narcissus, and maidenhair were sacred to him; black rams and ewes were sacrificed to him amid the shadows of night, and his priests had their brows garlanded with cypress wreaths. In Hades, the art he employed was weaving Zeus and Poseidon; only his hair hangs down somewhat wildly and fiercely over his brow, and his appearance, though majestic, as becomes so
mighty a god, has something gloomy and terrible about it. — The Plutonian theory in Geology, otherwise called Vulcanist or Huttonian, was opposed to the Nebulist or Wernerian. See GEOLOGY, Vol. V. p. 148, and HUTTON; and for the Plutonic rocks, see also IGNEOUS ROCKS.

Pluviometer. See RAIN-GAUGE.

Plymouth, one of the most famous of English seaports, an ancient parliamentary, municipal, and county borough, lies in the extreme south-western corner of Devonshire, 246 miles by rail (216 by road) WSW. of London, 128 SW. of Bristol, and 53 SW. of Exeter. It occupies the northern shore of Plymouth Sound (see below), immediately at the mouth of the Plym. The remaining space between it and the Hamaoze, the estuary of the Tamar, is occupied by the sister but much smaller town of Stonehouse (q.v.), while still farther to the west, along the Hamaoze itself, stretches the third of the 'Three Towns,' Devonport (q.v.). They are all, however, so united now by continuous lines of houses that, with their respective suburbs, they have lost their individuality, and to the stranger appear one great community. The chief government establishments are at Devonport—the dockyard, gun-wharf, steam factory, and principal barracks; while Stonehouse has its quota in the victualling yard, marine barrack, and naval hospital. Plymouth, which is more populous than the other two together, is at once the chief seat of commerce, trade, and manufacture, and within the 19th century displayed an enterprise which gives it a high place amongst provincial centres. The site is a very fine one. Between the two natural inlet harbours of Sutton Pool and Mill Bay stretches the bold rocky ridge of the Plymouth Hoe, the eastern end of which is occupied by a citadel built by Charles II. Northward the ground rises in a series of long hills, along which the town itself extends until it passes into a suburban hill of singular attractiveness. From the Hoe there are magnificent views both seaward and landward. Here, according to tradition, the captains of the fleet which assembled to meet the Armada whiled away the time by playing a game of bowls, which was interrupted by the news of the approach of the enemy: and here stand a tercentenary memorial to the Armada heroes (1890), and a statue (1884) of Sir Francis Drake (one of Beeld's finest works).

The upper portion of the lighthouse erected by Smeaton on the Eddystone (q.v.) was also rebuilt here in 1882-84. Old Plymouth is chiefly clustered round the shores of Sutton Pool—a dingy unattractive set of narrow streets; but of recent years miles of excellent thoroughfares and many handsome buildings have been erected, chief among them a noble Gothic guildhall, opened in 1874 by the Prince of Wales, Lord High Steward of the Manor ofil. The principal seat of the fine 15th-century church of St Andrew, Perpendicular in style, and restored in 1874-75 by Sir Gilbert Scott; Charles Church (1646-58) is a singularly good example of post-Reformation Gothic; the Roman Catholic cathedral is an effective Early English edifice (1838). The Coffroman collection of sketches by the leading continental artists is at the Proprietary Library; there is a good local museum at the Athenaeum; and among the numerous charitable institutions the first place is taken by the South Devon Hospital, opened in 1834 at a cost of £40,000. The town is served by both the Great Western and London and South-Western Railways. In Mill Bay are the Great Western Docks, now the property of the former company, which are capable of taking the largest merchant vessels. Sutton Pool, the ancient tidal harbour of Plymouth, is reoccupied to a large extent by the commerce of the port, the seat of the fisheries of the port, which are very important. Manufactures, mainly chemical, are carried on—at Cattewater chiefly, but also at Mill Bay. There is a large foreign, and a very extensive coasting trade, and the port is used by lines of passenger-steamers to almost every quarter of the globe.

Though only a fishing-village at the Conquest, under the name of Sutton, Plymouth has for centuries played a leading part in the nautical life. It was the favourite port of the Black Prince; the chief English rendezvous of Drake, Hawkins, Grenville, Raleigh, and their fellows; the final port of departure of the Mayflower with the Pilgrim Fathers. In the civil wars it sided with the parliament, and successfully endured a series of sieges and blockades extending over four years, sharing with Hull the honour of saving the parliamentary cause. It was also the first town to declare for William of Orange. In the great French war it rivalled Portsmouth in naval activities. Among its more distinguished natives are Sir John Hawkins, Sir Richard Hawkins, Sir Thomas Edmonds, W. H. Leach, Sir Thomas Penny, Sir W. Snow Harris, F.R.S., W. Elford Leach, F.R.S., with Northeote, Haydon, S. Prout, Sir C. Eastlake, P.R.A., and S. Hart, the artists. It is now an important scientific centre in connection with the Marine Biological Laboratory (opened in 1888), which publishes a Journal. Plymouth was first incorporated by Henry VI. in 1439, and has since always returned two members to parliament. Pop. (1801) 43,194; (1851) 52,221; (1871) 70,091; (1881) 76,980; (1891) 87,307.

Plymouth Sound, on the south-west of Devonshire, near the entrance of the English Channel, is one of the famous roadsteads of the world. It is a deep inlet, into which the river Tamar falls from the west, and the river Plym from the east. The extreme seaward boundaries of the bay, from which the Sound is so called, are Half Head (mentioned in Ptolemy) and Stoke Point, not far within which a third river, the Yealm, debouches. The Sound, however, is practically bounded southward by a line drawn from Penlee to Wembury Points, and northward by the Plymouth Hoe. Within these limits the depth ranges from 6 fathoms to 3 miles, while its landward depth is about 3. Immediately within Penlee Point, on the western side, is Cawsand Bay, formerly one of the chief anchorages of the port and navy, but so exposed to the south-easterly gales that it was at times very
PLYMOUTH

PLYMOUTH BRETHREN 231

dangerous; while if vessels anchored in the Sound had to clear the full fury of the south-westers. Hence Earl St Vincent, fifteen years afterward, drew a scheme for the provision of artificial protection, and in 1812 the construction of the Plymouth Breakwater was begun, plans prepared by Messrs Rennie and Whidby. This great national work is an artificial mole of stone, a mile in length, stretching across the middle of the Sound, 2 miles from the Hoe, and thoroughly protecting the inner anchorage. It was not completed until 1841, and cost £1,500,000 (see Breakwater). About half a mile from the Hoe is a little island, originally called Eddystone, then known as the Mount, and commonly Drake's Island. This is strongly fortified. A formidable stone fort has also been built on an artificial island immediately within the breakwater; while on either shore there are extensive forts and batteries—Bovisand and Stamford on the east, and at Picklecombe, Maker, and Tregantle on the west. The estuary of the Plym is called the Cattewater, and is a capacious and important inner mercantile anchorage, opening from the Sound eastward, and protected by the estuaries of the Yealm and Yealmpton. The estuary of the Tamar is called the Hameanoe and from the spot at which it enters the Sound between Devil's Point and Mount Edgecumbe to Saltash is nearly 4 miles in length—a still more valuable and thoroughly protected anchorage for vessels of the largest size, and occupied by men-of-war. In the Channel, 14 miles off the Sound, is the dangerous Eddystone Reed (q.v.), indicated since 1760 by lighthouses, and now rather a directing post to the port than a danger. Plymouth Sound is exceedingly beautiful, and has even been considered worthy of rivalship with the Bay of Naples. On its western shore is Mount Edgecumbe, the delightful seat of the Earl of Mount Edgecumbe, traditionally said to have been selected by Medina Sidonia as his share of the English spoil. Rame Head, crowned by the ruins of a medieval chapel, is one of the most picturesque headlands on the coast; and the estuary of the Yealm, with the peaked Meawstone at its mouth, is full of romantic beauty.

See R. N. Worth's History of Plymouth (1871; new ed. 1878); J. W. E. Top. and Biblioth. (1871); L. Jewitt's History of Plymouth (1873); and four works by J. R. Rowe (1873-76).

PLYMOUTH. (1) capital of Plymouth county, Massachusetts, on Plymouth Bay, 37 miles by rail SE. of Boston, is famous as the landing-place of the Pilgrim Fathers (q.v.). Plymouth Rock is a granite boulder at the water's edge on which they landed. It is covered by a handsome granite canopy, and there is also a national monument (1858-89) to the pilgrims; the pedestal, also of granite, stands on a hill overlooking the landing-place, and is 46 feet high, surmounted by a central figure of Faith, 33 feet high, with four allegorical stone figures representing Morality, Education, Freedom, and Law around the base. In Pilgrim Hall (1824-25) are preserved many relics of the first settlement of the country. The town has an iron foundry, mining mills, and manufactures cotton and duck, cordage, nails, tacks, and rivets. It is popular as a summer-resort, and contains a number of hotels. Pop. (1890) 734; (1900) 9592.

—(2) A borough of Pennsylvania, on the Susquehanna River, 20 miles by rail SW. of Scranton, in a coal region. Pop. (1900) 12,000; mostly foreigners.

—(3) The capital of Montserrat (q.v.).

PLYMOUTH BRETHREN, a name given by others to a body of Christians which since 1830 has extended itself throughout the British dominions and in some parts of the continent of Europe, parti-

cularly among the Protestants of France, Switzerland, and Italy, and also in the United States of America. The Brethren originated in a reaction against descrip-

tive High Church principles, as maintained in the Church of England, with everything of a kindred nature in other churches, and against a dead formalism associated with 'un evangelical' doctrine. Members of other religious communities formed in Plymouth and elsewhere were retired Anglo-Indian officers, men of unques-

tionable zeal and piety; but these communities began to appear almost simultaneously in a number of places. Their origin is, however, very much to be ascribed to the work of the young Baptist minister, Nelson Darby (1800-82), from whom the Plymouth Brethren on the continent of Europe are very generally known as Darbyites. Darby was a barrister, who under deeply religious impressions became a clergyman the Church of England, and served as a curate in Wicklow; but in 1827 he left the Church of England from consciences scruples, and became an evangelist un connected with any church. In this character he laboured both in England and on the continent of Europe, preaching in French, English, and German, and his experience was founded at Plymouth the congregation whence comes the name usually given to the communion; the Dublin assembly dates from the same year. He also gave utterance to his opinions in numerous pamphlets, in a quarterly periodical, and a long series of works. The beliefs of the Brethren, as in the case of the Brethren in general, are strictly Calvinistic: original sin and predestination, the efficacy of Christ's sacrifice, the merit of His obedience, the power of His intercession, the gracious operations of the Holy Spirit in regeneration and sanctification are prominent points. Pre-Millenarian views are generally entertained by the Brethren; and they usually practise the baptism of believers without regard to previous infant baptism. Recently among a section household baptism has been prac-

ticed. They partake of the Lord's Supper every Sunday, or 'first day of the week.' They utterly reject the rite of confirmation. Their most distin-

tinctive peculiarity, when contrasted with other Calvinistic churches, is their complete rejection of ecclesiastical organisation. They suppose the whole Christian church to be in the world, derived from truth and duty, like Israel of old, and there-

efore to have been 'corporately rejected of God,' and believe that the church consists of all true believers in the Lord Jesus to whatever denomina-

tion they may belong—holding uniformly that no unbeliever or unregenerate person ought to be recognised as in the church of God. They refuse to recognise any humanly devised form of church government, or any official or salaried ministry; they insist on the privilege and responsibility of every individual to minister according to his gift and ability, in order to the edification of the whole. Practically the number of those fitted publicly to teach or minister the Word of God is very limited, and those who are not fitted for such ministry are not encouraged and sometimes re-

strained.

They distinguish widely between pastors, teachers, and exhorters, whose ministry is to the church, and evangelists, whose ministry of the gospel is toward the world. Whilst disowning human qualifications and ordinations, and generally practising wholly as unscriptural the distinction of 'clergy and laity,' they hold that it is right to own such evangelists, pastors, and teachers as Christ the Head of the Church has bestowed and the Holy Spirit has called them to do. Such men and women wholly to the work of the gospel are supported by voluntary and unsolicited contributions. In their assemblies there are frequent pauses, and liberty
therefore for any member to lead in prayer or praise or to exhort or teach as he may judge to be for edification, guided by spiritually enlightened understanding of what is fitting and in harmony with what is in the Bible. Women in the fellowship take public part in the assembly. Perssons proved to have been guilty of the sins mentioned in 1 Cor. v. 11 are excluded from the fellowship, as well as those who deny foundation truths of Christian doctrine, until evidence of repentance satisfactory to all is given in the church. The Plymouth Brethren reject every distinctive appellation but that of Christians, although a special denomination is found necessary to designate them; no one not holding their views could remain associated with them. A schism took place among them in consequence of the growth of the movement in the 1840s.

Concerning the human nature of Christ: Darby vigorously opposing what he deemed a dangerous error, and he and his adherents utterly separating from the fellowship of those who maintained it, or refused to condemn it, and also from all who, even though holding the teachings of the Plymouth Brethren, refused to endorse the extreme form of separation demanded by Darby. The Darbyite section since Darby’s death has been more than once divided about various questions of doctrine and discipline. The less exclusive principles have attracted many away from the Church of the Plymouth Brethren, by the meetings continue to multiply and increase in Great Britain and Ireland, Canada, the United States, Australia, New Zealand, and elsewhere. The increase is mainly the result of evangelistic work. In the United Kingdom there are about 800 meetings; in Canada, over 100; in the United States, about 100; in Germany, 200; in France, 150; in Switzerland, 80; and in Holland, some 40.

See the works of Darby, Kelly, C. H. Mackintosh, and J. G. Bellett; and books for or against the doctrines of the Brethren by Trotter (1856), Groves (1867), Reid (1873), Miller (1879), Teoton (1883).

Pneumatic Despatch, the name given to a method of sending written documents, chiefly telegraphic despatches, through a comparatively narrow tube by means of compressed air and by a partial vacuum. Early in the 19th century Mr. Millinn proposed to construct a railway on this principle with a tube from London to the North that would be light. (see Murdoch). But Mr. Latimer Clark, C.E., was the first to carry out a plan for the transmission of telegrams by pneumatic power. In 1833 he obtained a tube laid between the central station of the International Telegraph Company and the Stock Exchange, the length of which was sufficient to make the despatches was propelled by a current of air produced by connecting the tube with a vacuum holder. An improvement on this was made in 1838 by Mr. Varley, C.E., who introduced compressed air for the outward and returned the vacuum method for the inward traffic. This method is still in use.

The essentials of a pneumatic despatch are the exhausting and compressing pumps worked by a steam-engine or other motor; a metal tube, which in England is usually a lead pipe, since it is easily made air-tight by soldering the joints; a small carrier of gutta-percha or other material to contain the despatches; and a suitable arrangement of valves at the stations for connecting the tube or tubes with the compressed air or vacuum mains. It has been found by experience that with heavy trains of carriages the pressures in the central tube in the London Post-office, a lead pipe 2¾ inches in diameter is a convenient size, and this is enclosed in an iron pipe for protection. The method of working is this: At the central station end of the tube there is a double sluice valve, and when the carrier is inserted into the pressure chamber (the widened end of the pipe) the lower slide of the valve is drawn so as to close the mouth of the pipe, but on the rod of the slide there is a stop which actuates a lever and rack, and this opens the upper slide in front of the carrier. At the same time, by a separate arrangement, a valve is opened to admit compressed air, which, when the carrier has arrived at the other end of the tube is signalled electrically, the slide is moved so as to cut off the air from the pressure main, and then the chamber at the mouth of the pipe is ready for another carrier. The far end of the pipe is drawn or attached to the central station by making a connection at that station with the vacuum main instead of the pressure main. For a distance of 1000 yards with a 2¾ inch tube the time of transit is one minute when the air pressure is 10 lb. per square inch or with an equivalent effective vacuum of 64 lb. per square inch. With the air pressure and vacuum usually employed, a speed of from 24 to 35 miles per hour is attained in tubes not exceeding a mile in length. The speed varies inversely as the square root of the length of the tube. According to an official statement prepared in 1887, the pneumatic post pipe of the London post-office has been gradually increasing until the system, which in 1854 was represented in London by one 6 horse-power engine working a single tube of a few hundred yards in length, comprised, thirty-three years later, in London alone, four 50 horse-power engines each individual engine being horse-powered at 1,815 r.p.m., and an aggregate length of nearly 34 miles. In 1887 there were in London and the provinces 128 tubes of a total length of 46 miles, requiring fifteen engines with a total of 379 horse-power nominal to work them; 86,000 messages a day were then passed through these post-office tubes. The newspaper offices in several of our large towns have pneumatic despatches in connection with the telegraphic instrument rooms of their respective post-offices. In Paris and some other towns on the Continent, instead of several tubes radiating from a central to outgoing stations as in London, one tube or tubes alongside each other from the central telegraph office form a continuous circular line with intermediate stations, and several carriers linked together are sent at one time. In the United States pneumatic despatches are employed in New York, Philadelphia, and Boston, giving good results in expedition and economy.

Pneumatic Railways and Tramways.—It has been several times proposed to construct pneumatic railways, one plan being to propel carriages by the pressure of a large tube of compressed or rarefied air. A piece of railway of this kind was laid down in the Crystal Palace grounds in 1865 by Mr. Rammel. It consisted of a single line of rails in a tunnel 600 yards in length, along which a carriage conveyed passengers. Motion was given to the carriage by using a fan or hollow disc 22 feet in diameter, which either condensed or rarefied the air as required according to the adjustment of certain valves. This railway did not continue long in operation. The driving of tramcars by compressed air appears more likely to be on a country line, and some tramcars in France tramcars have been propelled by the Mekanisi system of air pressure and local heating since 1876, and a tramway line worked on this principle was in 1889 opened at Paris. In 1890 traction by compressed air was tried at Chester, the tramcar being pulled by compressed air through a 2 miles’ journey, but having means of recharging the reservoir, if necessary, at intervals along the line. See TRAMWAYS.

Pneumatic Power (Transmission of).—The plan of laying down an extensive system of pipes through a city to supply compressed air for motive power of elevators, cranes, and other purposes in small, and
even in comparatively large, industrial establishments is now in successful operation in Paris. A complete plant to supply air pressure was first put down there in 1870 in connection with a pneumatic clock system, and about 9000 of these clocks are now kept going. But the demand for compressed air for other purposes increased rapidly, so that for some years past only a comparatively small proportion of what is supplied by the Paris company is required for clocks. This company has compressing engines, worked by steam, which have an aggregate of 3000 horse-power. These transmit air at a pressure of from 80 to 90 lb. per square inch through 30 miles of mains. The air in the branch pipes has its pressure somewhat reduced by passing it through a filter before being conducted to a motor, which obviates any inequality that might otherwise arise in the pressure if the air were admitted direct to the motor at what it stands in the mains. The amount of compressed air used by any individual or firm is measured by a meter. In 1880 works were established on a large scale in Birmingham to supply compressed air to that town by a system similar to that adopted at Paris. In both of these towns there is a large number of small workshops or industrial establishments where power supplied in this manner is used to drive small machines more economically than by any other method. Other applications of it are to raise water to the upper stories of a building from a well in the basement, for refrigeration, and for winding up telegraphic instruments.

**Pneumatic Gun.** See Air-gun, Cannon.

**Pneumatics** is a name, not very much used now, for the science that discusses the properties of gaseous fluids. It is therefore a branch of Hydrodynamics (q.v.), in the modern acceptation of that term. See also Atmosphere, Barometer, Gas, Sound, Velocity, Wave, Wind.

**Pneumatic Trough** is a piece of chemical apparatus devised by Priestley, by means of which gases can be collected in vessels for experiments or examination. It consists of a vessel of water, provided with a ledge or shelf at the depth of two or three inches from the top. The jars in which the gas to be collected are filled with water, are placed with their mouths downward upon the shelf, which is kept a little under water, so as to prevent the entrance of air into the jars. When the edge of the jar is brought over the extremity of the tube carrying the gas the bubbles of gas rise through the water, collect in the upper part of the jar, and displace the liquid.

**Pneumogastric Nerve.** See Nervous System, Vol. VII. p. 441, and Digestion; also Habershon, Pathology of the Pneumogastric Nerve (2d ed. 1885).

**Pneumonia** or Inflammation of the Lungs is the inflammation of the lungs with the necessary modifications, depending upon a number of distinct pathological conditions. The castrall inflammation of Bronchitis (q.v.) may extend to the alveoli of the lungs, producing scattered patches of catarhal pneumonia. The inflammatory changes in the lungs in consumption, including interstitial pneumonia, or cirsartosis of the lungs; in a few cases of syphilis; in wounds and injuries of the chest; in pyemia; in the last stage of many exhausting diseases, all come under this head. But the most important form, to which the term pneumonia is generally restricted, is that variously called acute, idiopathic, lobar, or croupous pneumonia, and is one of the most striking and definite of familiar diseases.

The changes occurring in an affected portion of lung are described in three stages. (1) **Congestion:**

the lung-tissue still contains air, though less than in health, and is gorged with blood. (2) **Red hepatisation:** the lung-tissue is solid like liver (hence the name), and is much more friable than in health; it still contains much blood, but no air, as the vessels are entirely filled with it. The exudation consists of fibrinous material, mixed with leucocytes and red blood-corpuscles. (3) **Gray hepatisation:** the tissue is still more friable and of a grayish colour, containing now little blood or blood-pigment; the exudation consists of fibrin, as the fibrinous material has disappeared, and it oozes in part from the cut surface as a purulent fluid. It is doubtful whether recovery can take place when this third stage has been reached. When the surface of the lung is affected Pleurisy (q.v.) is always present as well as pneumonia.

The inflammation never attacks the whole of both lungs at once; the right is more often affected than the left, and the lower part than the upper. A whole lobe, or a large part of it, usually suffers; sometimes more than one.

The disease sometimes begins suddenly with a severe rigor or shivering-fit, and the temperature rises rapidly—usually to 103°-105° F. The pulse and respirations are both quickened, but the latter much more in proportion than in most other diseases, a most important indication of the nature of the case, and of the severity of the malady (about 4 pulse-beats to 1 respiration), the proportion becomes 3 or 2 to 1. All the usual signs of fever are present; but the patient's face presents a characteristic dusky flush; there is frequently severe pain in the affected part of the chest, and usually more or less cough, painful, but short, and suppressed as far as possible. In most cases after a few days the spit becomes very viscid and tenacious, and assumes a rusty tinge; this appearance is almost sufficient by itself to show the nature of the disease; but spi fill as well as cough may be absent altogether. The physical signs of the disease are very distinct. There is dullness on percussion over the affected area; and on auscultation marked and very characteristic changes in the breath-sounds.

But if the inflammatory process happen not to reach a portion of the lung in contact with the chest-wall it may be impossible to detect anything abnormal.

It is always a serious disease; but the great majority of cases do recover. The circumstances which make it alarming is the fact that pneumonia is the disease, especially of the heart or kidneys; previous habits of intemperance; and advanced age, as it is much less fatal in youth and middle life than after the age of sixty. Yet sometimes even cases apparently far from hopeful ultimately do well.

In favourable cases the fever usually terminates very rapidly, by crisis, as it is termed; in a few hours the temperature falls five or seven degrees, and the patient's comfort becomes correspondingly relieved. But in a very large number of cases this takes place between the sixth and the eighth day; but it may occur earlier, or it may be delayed to the fourteenth. After this has taken place the exudation in the affected portion of lung is gradually expectorated and absorbed, and as a rule perfect recovery is complete without inflammation.

In a considerable number of cases pneumonia seems to be brought on by exposure to cold or wet. But in the majority no such cause can be traced. Only in very exceptional instances does it seem to be infectious; but evidence on a small scale of not infrequent occurrence, and sometimes assume large proportions. These facts, among others, have led many observers to believe that acute pneumonia ought really to be classed not with local inflammations, but with specific fevers; and that the
inflammation in the lungs has the same relation to the disease as the ulcers in the intestines to typhoid fever, or the inflamed throat to scarlet fever. In 1882 Professor Bedson described a form of micrococcas as occurring in the lungs in pneumonia. But it is doubtful whether it is always present in this disease, and it is sometimes found in other conditions.

It must at present be regarded as an open question whether it is really a simple inflammation, with accompanying febrile disturbance, or a disease analogous to the infectious fevers, with a special local manifestation in the lungs.

The recognised treatment of pneumonia passed through curiously varied phases during the 19th century. Free and repeated bleedings, with extending rapes of a region. Poultries during the earlier decades, were superseded about the middle of the century by equally extensive administration of alcoholic stimulants. But it was gradually discovered that many cases recover perfectly with no other treatment than careful nursing. Its stream began from 1850. It is now an established fact that it has been assigned to drugs only a subordinate place. Rest in bed in the recumbent position; a plentiful supply of fluid nourishment; light poultices, or a thick layer of cotton-wool, over the affected part, are often all that is necessary in a young subject. The danger must be feared in this disease, however, is generally weakness of the heart; and to patients of feeble constitution or advanced age stimulants—digitalis, ammonia, alcohol, &c.—are usually administered, often in large and frequent doses.

Sturges and Coote, History and Relations of Pneumonia (2d ed. 1890).

Po (anc. Eridanus and Padus), the largest river of Italy, rises on Monte Viso, one of the Cottian Alps, at an altitude of 6405 feet, close to the French frontier. It flows eastward for upwards of 20 miles, when, arriving before Saluzzo, it emerges from its rocky defiles and enters upon the plain. From Saluzzo to north of Turin and Chivasso; there it changes its course toward the east, in which direction it flows to its embouchure in the Adriatic. Upwards of 55 miles from its mouth, above Ferrara, it begins to form its delta, 50 miles wide from north to south. The delta is gradually sinking towards the sea, but the Po, flowing from the seashore, now stands 4 miles inland. The Po receives from the left the Ticino, Adda, Mincio, and other streams, and from the right the Trebbia and others. It has an entire length of 360 miles, and drains an area of nearly 28,900 sq. m. Below Parma it forms from the pre-Roman days to the present time, been embanked—in some places with double embankments; and the bed is now high above the plain. It has always been difficult to cross, owing to its width and, still more, the great volume of its waters; hence the strategic and commercial importance of such places as Piacenza and Turin, where the easiest fords are.

Poaceae. See Grasses, Pasture.

Poaching, though not strictly a legal term, has so long been appropriated in popular speech to describe a well-known offence that it is now usually adopted in legal works. It means trespassing on another's lands in pursuit of game; and it is likewise extended to the encouragement of unlawfully fishing in another's waters.

(1) As to Poaching Game.—The general law as to who is entitled to game, and in what circumstances, is stated under the head Game-Laws. In England there are a Day Poaching Act and a Night Poaching Act, imposing penalties on poachers. By the Day Poaching Act, 1831, whoever unlawfully poaches upon any shoot, (q.v.), rabbits, woodcocks, snipe, quails, or land-rails is liable to a penalty of £2. Any person whatever, whether interested in the lands or not, may institute the proceedings for the punishment of the poacher; and the informer is entitled to half the penalty, or his half going to the poor of the parish. When a poacher is found trespassing on a person entitled to the game there, or the tenant, or a gamekeeper or servant of either may demand the poacher's name and place of abode, and if it is refused may arrest such poacher, and take him before a justice of the peace; but the poacher must be taken within twelve hours before the justice, otherwise he is entitled to go at large. In such a case a penalty of £5 may be inflicted. If game he found on the poacher at the time he is caught, and it appears to have been newly caught, the party who is entitled to arrest him is entitled to seize the game also. If the poacher when convicted do not pay the penalty within the time fixed by the justices, he may be committed to the house of correction for a period not exceeding three months. Any person may apply against his conviction to the Court of Quarter Sessions; but he must either remain in custody in the interval, or give security for the costs. The offence of poaching is punished more severely when five or more go out together, and in such case each is liable to a penalty of £5. Moreover, if any of these five or more persons, acting in concert, be armed with a gun, and use violence, each is liable to an additional penalty of £5. By the Night Poaching Act, 1828, which applies to the United Kingdom, it is provided that any person by night, or in the day, poaching in any wood, or other place, is punishable by imprisonment for three months; and for a second offence shall be committed for a period not exceeding six months. The convicted person being in each case liable to a further term of imprisonment on failure to give securities at the end of his sentence; and for a third offence shall be guilty of a misdemeanour, and be liable to penal servitude or two years' imprisonment. In such cases, where the offender shall have been apprehended, and in the act, the owner or occupier of the land or his servants may arrest the poacher, and take him before justices. If the night-poacher, when arrested, use firearms, sticks, or offensive weapons, he shall be guilty of a misdemeanour, and be punishable by penal servitude or two years' imprisonment. In case of three or more night-poachers being armed with guns, bludgeons, or other offensive weapons, each is guilty of a misdemeanour, and is liable to penal servitude or imprisonment for three years. The provisions of the Night Poaching Act, by the amending Act of 1844, extended to public roads and highways, it having been found that the original act was evaded, and the risk of murder greatly increased by poachers frequenting such places.

Under a former law it was, as already mentioned, incompetent for any person except the owner or occupier of the lands or their servants to apprehend the poacher, and even this could be done only when the poacher was caught in the act on the lands; and hence even constables had no power to seize the poacher, though he might be on such lands. But by the Poaching Prevention Act, 1862, which applies to the United Kingdom, if a constable has a suspected poacher in any public place, whom he has reason to suspect of
coming from land where he has been poaching, and of having in his possession game unlawfully got, or a gun or net, such constable may stop and search the poacher; and if game, or implements for taking game, be found on him, may seize and detain them, and summon the poacher before the Justices. If he cannot prove the game was lawfully procured by circumstantial evidence or otherwise that such game was procured by poaching, or that the implements were used for poaching, the poacher may be fined in a penalty of £5, besides forfeiture of the game, and guns, nets, and other implements which he may prove to be his property, and he may also be summoned and search any cart in which he suspects there may be such game or implements. The person convicted may appeal, if he chooses, to the next Quarter Sessions, or, in certain cases, to the Court of Queen's Bench. A conviction can be obtained only in cases of actual seizure of game or implements, but for a conviction it is not necessary that the poacher should be seen actually committing the offence. Poaching hares or rabbits by night in any warren or breeding-ground is a misdemeanour under the Night-poaching Act, 1861. This act does not apply to Scotland.

As game is in the category of wild animals, in England the poacher is entitled to keep the game unless it was both started and caught on the same person's lands. But, as stated above, game may be in reality only stealing under a wilder name, game being as much the fruit of the soil, dependent upon the care and protection of the owner or occupier, as apples or turnips, and that the transition from habitual poaching to stealing is not only easy, but inevitable. The administration of the law by justices, many of whom preserve game, is also objected to. As regards Scotland this objection has been removed by the Game Laws Amendment Act, 1877, under which all summary prosecutions for poaching must be conducted before the sheriff or the petty sessional court of the county or county-town. See Oke, Game Laws (new ed. 1881); Neville, Game Laws (new ed. 1884); Forbes Irvine, Game Laws of Scotland; A. Porter, The Gamekeeper's Manual (2d ed. 1883); Kent, The Fish and Game Laws of the State of New York (1883); and R. Jefferies, The Gamekeeper at Home (1878), and The Amateur Poacher (1880); John Watson, Poachers and Poaching (1881).

(2) Poaching Fish is the unlawfully entering on another's fishery in order to catch fish. Salmon-poaching is illegal or illegal and dangerous because of its dependence on the sea and in all navigable rivers as far as the tide flows; and where he can fish he can catch salmon as well as every other kind of fish. But there is an exception to this generality, which consists in this, that as the crown could before Magna Charta (which took away such right) legally grant a certain fishery in a river to an individual, and as this was, in point of fact, often granted, it follows that it is not uncommon to find, even at the present day, an individual, generally the lord of an adjacent manor, still claiming a several fishery in these places. If he can prove this, he can stop other fishers, and if as far back as one or two centuries it will be inferred that his right dates from before Magna Charta, and it will therefore be sustained. When such is the case the public have no right to fish even in a tidal river or the sea at the specified places, the sole fishing being vested in this individual owner. In streams not tidal the rule is that each riparian owner.—i.e. the owner of the lands on the bank of the stream—has a right to a several or exclusive fishery up to the middle line of the stream. If he is owner of the lands, he has the exclusive fishery in the whole of the stream, so far as his lands extend. As to ponds, whoever is owner of the soil is the owner of a several fishery therein. As to lakes, it is not clearly ascertained how the fishery is to be divided between the owners of the lands therein, but it is supposed that if a highway adjoins a private stream any one may fish in the stream or angle there; but this is a delusion. Nobody is entitled to use a highway for the purpose of fishing or pursuing game, the use of the highway, so far as the public are concerned, being confined to the purposes of travelling or transport. The general rule as to all several.—i.e. exclusive—fisheries is that whoever poaches the fish commits an offence, for which he may be summoned before justices and fined £5, over and above the value of the fish poached; and the person who poaches adjoining the dwelling-house of the owner of the fishery it is a still higher offence, for it is then an indictable misdemeanour. The Fish-poaching Code of England is contained in the Larceny Act, 1861. It is immaterial what kind of fish is caught by poachers, and how they are caught. But a milder punishment is awarded to the poaching angler, for even though he poach in a fishery adjoining the owner's dwelling-house he incurs a penalty of only £2. Whenever a fish-poacher, other than an angler, is caught in the act of poaching he may be at once apprehended, not only by the owner of the fishery, but by anybody; but this can only be done while he is in the spot or near it, for he is entitled to the open highway and unencumbered lands before being arrested he cannot then be apprehended, but can only be summoned before justices in the usual way. In this respect a privilege is given to anglers, for in no case can these be arrested, if they are entitled to the fishery, which is not the case with the poacher, whatever other punishment he may incur, does not lose his fish. With regard, however, to the poaching implements, such as nets, it is
POCAHONTAS

PODARGUS

POCHARD (Fuligula), a genus of diving ducks which are marine during the greater part of the year. One of their distinctive structural features is a membranous lobe on the hind toe. The Common Pochard (F. ferina) is a winter visitor to Britain, and sometimes breeds by the shores of inland meres. The Red-crested Pochard (F. rufiacus) is a rare winter visitor to Britain and the African Pochard (F. nyroca), though the Tufted (F. cristata) and the Spoon (F. marila) are much commoner, and sometimes breed in suitable inland resorts. Nearly allied to F. ferina is an American species (F. americana), and the Canvas-back Duck ('q.v.) also belongs to the same genus.

POCKINGTON, a market-town in the East Riding of Yorkshire, 16 miles ESE. of York. It has a good Early English church (restored 1850) and a grammar-school (1514; reconstituted 1876), where Wilberforce was educated. Pop. 2753.

POCOCK, EDWARD, a learned Orientalist, was born in 1684, and educated at Corpus Christi College, Oxford, of which he was elected fellow in 1728. He early devoted himself to oriental studies, and sailed for Aleppo in 1630 as chaplain to the English factory, but returned in 1636 to fill Land's newly-founded Arabic chair at Oxford, and received in 1643 the college living of Wychbury. His estimable character and great learning raised up for him during the troubles friends like Selden and Owen. He was appointed to the chair of Hebrew in 1648, but his inability to take the engagement of 1649 deprived him of the salary down to the Restoration. He survived till 1701. Pocock's learning was really remarkable, even apart from all allowances for his time. His Specimen Historic Arabum (1649), abridged from Abulfaraj: Porta Mosis (1655)—extracts from Maimonides' Arabic commentary on the Mishna; the Annals of Eutychius (1666), in Arabic and Latin; and an edition of the Arabic history of Barbaraeus (1663), were followed by Commentaries on Mica (1677), Malachi (1677), Hosea (1685), and Joel (1691).

POCOCKE, RICHARD, 'the Traveller,' was born at Southampton in 1704, and educated there and at Corpus Christi College, Oxford. Predecessor successively of Cocks and Water, Bishop of incomes (1745), in 1756 he was consecrated Bishop of Osory, and had just been translated to Meeth, when, on 13th September 1756, while on a visitation, he died very suddenly at Charleville, near Tulhmore. His travels, which took up nearly nine years of his life, and in which he must have ridden some 52,000 miles, are described in two folios dealing with his four years' wanderings in Syria, Egypt, and Mesopotamia (1743-45), in a volume on his tours in Scotland (Scottish History Soc., 1887), in two on his tours through England (Camden Soc., 1888-89) and in one on Ireland (edited by J. T. Stokes, 1891) —books that are as dull as they are valuable. Pococke was, moreover, the pioneer of Alpine travel, for in 1741 he led a dozen Englishmen, all strongly armed, to the Vale of Chamouni, whose grateful inhabitants carried his name and the date on a huge granite boulder close to the Mer de Glace.

POD. See FRUIT.

PODAGRA. See GOUT.

PODARGUS, a genus of birds nearly allied to the true Grouse. They are at home in New Guinea and Australia, are arboreal and nocturnal in their habits, and feed on large insects, which are mostly caught about the trees. Some of them are so expert in capturing trees that Gould says they may be occasionally caught by the hand, or one may be shot without wakening its neighbour. They make rough nests in the eucalyptus or casuarina trees, lay two eggs of spotted white, and the...
work of hatching is shared by both sexes. A podaroma is usually larger than a goose-tuck, and has a wider gape; the oil-gland seems to be absent, and the feathers two remarkable tufts of British brittle feathers, known as "powder-down patches." One of the Australian species, *P. cuvieri,* disturbs the night by a hoarse cry resembling the syllables "More Pork or Mopake," by which names it is therefore known in New South Wales.

**Podestà** (Lat. *potestas,* "power"), an Italian municipal magistrate, sometimes with supreme administrative and military power, sometimes merely judicial.

**Podgoriza,** a fortified town of Montenegro, 16 miles E. of Cetinje, was ceded by Turkey in 1879. Pop. (1885) 6534.

**Podiebrad,** George Bocsko of Podiebrad, Bohemian king, was born of a noble family at Podiebrad on 6th April 1420, and became an adherent of the moderate party of the Hussites (q.v.). When the Catholic barons (1438) carried the election of Albert V. of Austria (11. of Germany), Podiebrad allied himself with the Utraquists in Tabor, where he offered the sovereignty of Bohemia to Casimir, king of Poland. After forcing Albert to raise the siege of Tabor and retire to Prague, Podiebrad was recognised as the leader of the Utraquists; then he seized upon Prague (1448), and got himself made governor or regent of Bohemia, from 1453 to 1457, for the young king Ladislaus. On the death of Ladislaus, Podiebrad was chosen his successor, and was crowned early in 1458. By skilful management and wise policy he succeeded in allaying the bitterness of religious zeal, but only for a while. In 1462 he decided to uphold the terms of the *compacts* of Prague (1453); this angered the pope, Pius II., and he was only prevented from excommunicating Podiebrad through the special intervention of the emperor. The next pope, however, Paul II., did in 1466 promulgate against him the ban of excommunication. Matthias Corvinus of Hungary was the only prince who took the field to enforce it; but he Podiebrad surrounded at Wilamow (1469) and forced into a truce. Nevertheless Matthias was crowned king by the Catholic barons at Olmütz immediately after his death. Podiebrad died on 29th March 1471, having already made arrangements whereby a Polish prince should succeed him.

**Podocarpus.** See Coniferæ.

**Podolia,** or Kamenetz, a government of West, or 'White' Russia, north of Bessarabia, and bordering on the Austrian frontier. Area, 16,224 sq. m.; pop. (1891) 2,617,253, the majority of whom are Hungarians. The surface is a tableland, strewn with hills; nearly three-fourths is arable or available for pasturage.

**Podophialama** (Gr., 'stalk-eyed'), a name often applied to a section of *Crataeæa* (q.v.).

**Podophyllum,** a genus of plants comprising two species, variously ranked by botanists in the natural order Ranunculaceæ, or made the type of a small distinct order, Podophyllææ or Podophyllææ, differing from *Ranunculus* chiefly in having a solitary carpel. The genus Podophyllum has three sepals, six to nine petals, twelve to eighteen stamens, a broad round stigma, seated almost on the top of the germen, and a many-seeded berry. *P. petasum* is a perennial plant, common in North America, and grows in rich woods and on the shady banks of streams, and is known as May-apple, because it flowers and ripens its fruit very early in summer; also as Hog-apple and Wild Lemon. The fruit may be eaten, but is not agreeable. All the other parts are actively emetic. The other species (*P. emodi*) is a native of the Himalayas, and has the same medicinal properties, but in 1859 was shown to yield three times as much of the valuable resin as the American plant.

**Podophyllum** is the resin obtained by means of rectified spirit from the root. In the English Pharmacopœia the root is official, but is only used to prepare the resin (*Podophylli Resina*). The latter is an active purgative, and seems to have the power of relieving the liver by exciting copious biliary discharges. The dose is ½ to 1 grain; its action is slow, generally taking about eight hours. It is apt to grip, and hence is usually given along with carminatives, or in small doses combined with other purgatives.

**Podura.** See Spring-Tails.

**Poe,** Edgar Allan, a talented American littératurist, was born at Boston, January 19, 1809. His mother, Elizabeth Arnold, was an English actress; his father, David Poe, a player of loose habits, the son of a revolutionary veteran at Baltimore. Orphaned at Richmond in his third year, Edgar was adopted by John Allan, a wealthy and childless merchant, who gave him more care than affection. In 1815 the family went to England, and the boy was sent to school at Stoke Newington, a suburb of London. From their return in 1820 till 1825 he attended a classical school at Richmond. The year 1826 was spent at the University of Virginia. Offended by his dissipation and gambling debts, his patron removed him to the counting-room, whence he presently absconded to Boston. Here he published *Tamerlane and other Poems,* by a Bostonian, 1827, a pamphlet of 40 pages (reprinted in London, 1884). Under the new pressure of poverty he enlisted, May 26, 1827, as Edgar A. Perry, giving his age as twenty-two. He served, apparently without fault, in the First Artillery at Forts Independence, Moultrie, and Monroe, and rose to be sergeant-major, January 1, 1829. He now effected a reconciliation with Mr Allan, who procured his discharge, April 15, and after a year's delay his admission to West Point. Meantime his second volume, *Al Aaraaf, Tamerlane, and Minor Poems,* appeared with his name at Baltimore, 1829, 71 pages. He entered the Military Academy, July 1, 1830, recording his age as nineteen. Discipline and constraint did not suit him, and by deliberate neglect of duty he caused his dismissal, March 7, 1831. By this conduct he lost any remaining hope of favour from his patron, and was thrown finally on his own resources, which were probably confined to cadet subscriptions to his *Poems.* The volume appeared as a "second edition" (it was really a third) in
New York, 1831, 124 pages, and contained Irosfel, his earliest poem of value, and To Helen, in a first draft.

Of his life in Baltimore during the next two years few records remain. Here occurred his earliest love-affair, which came to nothing (see 'Poe's Mary') in December 1833. Nearly the fourth of his pen was the $100 prize won by A MS. found in a Bottle, in October 1833. He declined an invitation to dinner 'for reasons of the most humilitating nature—my personal appearance.' John P. Kennedy befriended him, and even, by the testimonial he paid him, showed his approval. From this time he lived with his aunt, Mrs Clemm, and wrote for the Saturday Visitor. Not long before Mr Allan's death in March 1834 Poe made an attempt to see his foster-father, who drove him from the room; this incident, like many others in his life, has been exaggerated. His connection with the Southern Literary Messenger began with its publication of his tale Berenice in March 1835; a few months later he went to Richmond as its assistant-editor. The Clemms soon joined him, and on May 16, 1836, he married his cousin Virginia, who then was nineteen, though a friend swore that she was 'of the full age of twenty-one.' For more than a year he worked hard and usefully on the Messenger, which printed many of his tales, criticisms, and poems, gaining great repute thereby. But Poe was 'irregular, eccentric, and querulous,' and these qualities, with the aid of stimulants, cost him more than one place. He left Richmond in 1837, and after a year or less in New York, of which the chief apparent fruit was The Narrative of Arthur Gordon Pym (1833; 198 pages), in the summer of 1838 established himself (if he could) and at any time to be established in Philadelphia.

Here he prepared The Conchologist's First Book (1839), the matter of which was taken from Cuvier, Wyatt, and Brown; procured at length the publication, without profit to himself, of Tales of the Grotesque and Arabesque (2 vols. 1840); was connected with Burton's Gentleman's Magazine (1839); projected in 1840 the Penn Magazine, which came to nothing, and in 1843 The Stylus, which he never gave up the hope of starting; and for a year (1842-43) edited Graham's Magazine, then in the Pioneer period. His life had been one period of sobriety and patient though ill-requited labour would be interspersed with fits of reckless indulgence and months of desperate poverty. His wife's dangerous illness, caused by the rupture of a blood-vessel while singing, unnerved him, and weakened his always slight power of self-direction. A second prize of $100, won in 1843 by his wonderful story The Gold Bug, again saved the little household from starvation or near it.

In April 1844 he removed to New York, and from October to March following assisted Willis on The Broadway Journal. His poem Home, Home appeared January 29, 1845, and won immediate fame. For a few months he was associated with C. F. Briggs in the Broadway Journal, which became notorious by his assaults on Longfellow as a plagiarist. In this year he published a volume of Tales, and The Raven and other Poems. In the spring of 1846 he occupied the famous cottage at Fordham. Here, January 30, 1847, in deepest poverty, Virginia Poe died, an attractive and pathetic figure, retaining her fragile and childish beauty to the last; she was but twenty-four. Her mother was more than a mere, but a wondrous life of her own, and his book what was best in his nature, and afforded such measure as he attained of happiness.

Except for The Bells, The Domain of Arnheim, the wilful psycho-astronomical 'prose poem' Eureka (1848), and a few minor pieces, the brief remainder of his life might be advanced to beget forgetfulness. Unable to stand alone, he sought vainly, and with an eagerness that approached insanity, to replace what he had lost. He was no libertine; his writings and his life were chaste; with women he was deferential, tender, chivalrous. He idealised them, and in the ensuing years for thirty of his remaining years he could not keep his imaginations in their proper place. Mrs Whitman was not the only object of his homage, and his frantic appeals to her, strangely intermingled with bar-room potations and an attempt at suicide (November 1848), were both controversial and mischievous. From a mind of a mind unhinged. Two months later he was deep in pen-work, and wrote to his 'Annie' that he was 'so, so happy,' with 'how great a burden taken off' his heart. In the spring Mrs Clemm wrote to the same 'Annie,' 'I thought he would die several times. I wish we were both in our graves.'

Starting southward, June 30, he had an attack of delirium tremens in Philadelphia. Recovering, his ticket was furnished by friends who considered it unsafe to trust him with money. He spent over two months in Hells, and at Norfolk, and receiving many attentions. A physician warned him that 'another such indulgence would probably prove fatal.' He became engaged to a lady of means, and about September 30 left Richmond, intending to wind up his affairs in the north and return for his wedding in October. On the 3d of October he was found in a wretched condition at a voting-place in Baltimore and removed to a hospital, where, after expressing the most poignant remorse, he died, October 7, 1849.

Poe's character has been the subject of much heated discussion. Many of his associates, literary and otherwise, have written of his work and of his life. The Memoir prefixed to vol. iii. of his collected works (1850), but since suppressed. Efforts to rehabilitate his memory have been equally far from the truth. After all allowance made for the infirmities of a sensitive spirit, bearing an inherited taint and bowed down by 'unnerving disaster,' the fact remains that he was the main author of his misfortunes. His splendid intellect seemed to lack certain qualities bestowed on common men; his moral vision was less clear, his sympathies were narrow, his will was far weaker than a man's should be. His temperament was feminine, and the 'Imp of the Perverse' was always at his heels. At forty he was no better nor worse than at seventeen, except that his constitution was undermined by excesses. Always he was isolated, absorbed, self-centred, visionary, hopelessly impractical. He wrote to Lowell in 1844, 'My life has been sehr, impulsive, passion, a longing for solitude, a scorn of all things present.' The kindly Briggs, after months of daily intimacy, called him 'characterless' and 'utterly impractical.' He had qualities enough to know that his brilliant writings found with difficulty a slow market and poor prices, but more so that he perpetually sold and resold old things for new. He was more diligent in defending his own ends than in seeking them, in making enemies than in keeping friends. Except Willis, he quarrelled with his employers and associates; men trusted or befriended him to turn from him in the end, and usually with speed. The direct necessity could teach him prudence only by fits and starts; he was not responsible, reliable, respectable as a man; not, upon his own estimate, a man, and his house a failure. His wife had Beauty, caring little for her elder sister Truth; from youth he falsified the facts and dates of his own life, so that his history became a puzzle to be solved by slow and painful labours. Profoundly unmoral, morbid and hectic in his moods, he could bear neither
prosperity nor adversity; 'any motion would up-set him, and his worst falls were after successes, or with success just in sight.'

A member of the seraph and the tramp, he oscillated between the skies and the gutter, gravitating gradually downwards, because he had no god but self. Ambition, aspiration, self-respect, and the strongest love of wealth—these three, and for one devoted child-wife—could not keep him from the brandy and opium which he knew to be his poisons.

As to his genius there is little room for question. Weird, wild, fantastic, almost ghoulish (judged by its results), finding its joy in gloom and its chief inspiration in the dreams and imaginations of dead women, dwelling by choice and habit on themes of ruin and desolation, on the awful, the horrible, even the foul, it was yet most genuine and notable; if not of the highest order, among the most picturesque and striking gifts ever vouchsafed to man. 'everything is subordinately served. In these, and in the more personal of his tales, wherein great wit and madness mingle, he was 'the poet of a single mood.' He will be long remembered for a few poems and many masterpieces of brief, pure prose. His only public walk he stands unsurpassed if not alone, with a halo of mystery, gloom, and terror about him.

Apart from earlier sketches, and Mrs Whittman's *Poë and his Critics* (1809), his life has been written, generally for some reprint of his works. by J. H. Ingram (1874 and 1890), E. H. Stedman (1853; see the six-volume edition of 1884), E. L. Didier (1876), and W. F. Gill (1877). G. E. Woodberry ('American Men of Letters,' 1865) unearthed some new facts. See also E. C. Stedman's *Poe* (1881). An edition by Stedman and Woodberry contains memoir and introduction (10 vols. 1895-96); another edition (10 vols. 1895-96), published by Lippincott, has neither.

**Poerio, CARLO**. Italian patriot, was born on the 10th of December 1803, son of a Neapolitan lawyer who had suffered imprisonment and exile in the cause of liberty. He accompanied his father into exile, but on his return became an advocate at Naples. He was repeatedly imprisoned for his services to the liberal cause; and in 1848 he organised the famous demonstration of the 27th January, which was destined to precipitate the constitution of the 10th February. Under it he was successively nominated director of Police and minister of Public Instruction; but he soon resigned, and was appointed deputy for Naples to the parliament. On the 19th July 1849 he was summarily charged by the provisional Government with the society 'the Italian Unity,' and condemned to irons. With fifteen others he was confined in one small chamber in the island-prison of Nisida. Diplomatic protests from various governments—Mr Gladstone's was an ordered one—had brought from Rome only a tardy and feeble protest in 1850. The allies, however, soon saw that the modern nation had sounded the first trumpet-call of Italian liberty—and eloquent denunciations of the royal tyranny moved Ferdinand II. at last in 1858 to ship sixty-six prisoners to America. They persuaded the captains to land them at the shore, and for one month was confined by Lordown to Turin. There he became a member of the parliament, and in 1861 its vice-president. He died at Florence, 28th April 1867.—The elder brother ALESSANDRO (1802-48); who fell in battle for the liberation of Venice, shared his father's energy, spirit and devotion, and devoted his life mainly to poetry and patriotism. His poems, which contain some of the most stirring Italian songs of freedom, have been repeatedly published. See a monograph on Alessandro by Imbriani (Naples, 1884).

**Poet Laureate. See LAUREATE.**

**Poetry.** That one of the fine arts which employs rhythmical language as the medium of its expression. The present form of the word is of French origin, and was first used as *poetry* (1542), *poeti* (1547), *poetrie* (1566), and *poetry* (1603), as a noun *poetic,* and both are derived from the Greek *poietes,* 'to make.' A poet was *poietes,* 'a maker or composer,' and poetry *poiesis,* 'the act of making or forming.' A poem was *poiesis,* 'a thing made and finished.' Into all these forms there entered the conceptions of artistic fashioning, and poetry from the first was felt to be, like sculpture, painting, or music, the work of a creative craftsman. As we cannot conceive of sculpture without something carved or modelled, or of painting without something painted, so poetry cannot, in the first instance, be conceived without the coincident idea of language rhythmically arranged. If this idea be absent the term must be used allusively or figuratively, as its counterparts often and legitimately are in the cases of those other arts. But to the primitive conception of poetry rhythm is absolutely necessary. In other words, it is only by a license, and in a sense which is unscientific, that we can speak of anything which is not composed in verse as poetry. To this rule, however, there are some conventional exceptions which are not present in his own work.

Verse, therefore, is the essential vehicle of poetry, and on the varieties of versification the external form of any given poetical product depends. That species of rhythm on which verse is founded is the law of regularly recurring succession of articulate sounds. Verse was defined by Dr Edwin Guest as 'a succession of articulate sounds regulated by a rhythm so definite that we can readily foresee the results which follow from its application.' The definiteness, repetition, and formal character of verse-rhythm distinguish it from that laxer and more indulating rhythm which gives charm to fine prose. The difference is one not of amount but of kind. All good verse must be severely regulated, and must obey the laws of its own prosody. The rhythm of prose, on the contrary, must, in order to be good, be recurrent, and be unrecurrent. No greater fault can be committed in prose than the intentional or even accidental introduction of passages which can be read as verse—that is, as recurrent rhythm. Poetry, therefore, in the English sense, is an external form, an arrangement of syllables into verses or staves, distinguished by the rhythmical accidents of quantity and accent, and effected by the law of succession.

This definition of the external form of poetry, however, is not an adequate definition; and to complete it is admittedly so extremely difficult as almost to defy expression. In defining the term poetry,
POETRY

Nevertheless, as an English word, the lexicographers have probably been too much rather than too little affected by the necessity of including a spiritual meaning. Hardly any one has attempted to mean something which excludes unsuccessful effort in rhetorical expression. Hence a certain confusion between the external and the internal, between a craft and an ecstasy. It would be well, perhaps, to bring the term back to its more exact meaning, but it is too late to hope to do this. Poetry must continue to mean not merely language arranged in rhetorical sequence, but verse which is also inspired by imagination, and which attains a measure of perfection in that degree at which it abides. The degree may be a high one, but it is infallible that the rhetorical laws are followed, the work produced must not be refused the title of poetry. The word, indeed, is capable of much expansion. Any man who has written what the world accepts as a *messe*, a finished composition in verse, is allowed the name of poet andlauncher. But our attempts, even though many of them are unsuccessful, are broadly defined as "poetry." The presence of high imagination, and of a brilliant propriety of language, are presupposed in all that is called poetry, but the word must be extended to much that is not very lofty nor very skilful if we are not to slip into pedantry in its use. Wordsworth at one time was of opinion that the only strict antithesis to *Prose* was *Metre*; but it is simpler, as well as more exact, to understand by poetry metrical composition, not troubling ourselves more than is absolutely necessary in its definition about the quality of high imagination. This latter is essential indeed to the best poetry, but not to all poetry in the colloquial use of that term.

In some languages, and particularly in French, *rime* (constantly misspelt *rhyme*, which is a meaningless arrangement of letters formed in imitation of *rhythm*) is an essential part of the form of poetry. In other languages, as in ancient Greek and Latin, *rime* does not exist. In English poetry final *rime*, though not essential, is extremely common, and is the necessary ornament of the main classes of lyrical composition. *Rime* is a correspondence of sound between syllables which occur at regular intervals, and in final *rime* that recurrence always takes place at the end of a verse. It may be single, double, or even triple. *Propriety* and *vigour* in *riming* are important portions of the art of poetry that *rime* cannot be overlooked in the briefest survey. Where *rime* is not rejected altogether, as in blank verse (and in some strophic measures of doubtful value), it forms a main ornament of English verse-composition. One of the chief effects of which poetry produces is due to the skilful arrangement of these recurrent sounds. It is only a poet of great resource and infinite accomplishment who can safely dispense with this fortunate regulation of *rime*. To one who knows his business, the above remarks may be of considerable comfort and encouragement. As Dryden has excellently said, "That which most regulates the fancy and gives the judgment its busiest employment is like to bring forth the richest and clearest thoughts."

It is a popular error that the necessity of finding a *rime* checks the inspiration of a poet, and that he would be more fortunate if he could contrive to do without it. The universal testimony of the poets themselves does not support this notion. The best writers of verse have been unanimous in declaring that the more distinct and spontaneous are the verse-expressions given, the more skilful the brain for verse-expression the more rapidly and inevitably do the *rimes* occur in logical sequence, the proper word fitting into its proper place with as little conscious brain-effort as the proper term or the proper form does in the work of the painter or the sculptor. If this be so, and it seems impossible to doubt it, the difficulty which the unskilful versifier finds in *rimming* is but another safeguard to prevent us from incompetence. For those readers who declare that *rime* gives them no enjoyment, and is only an interruption of the sense, we can but pray that ears may be added to them.

The recognised species of poetical composition are numerous, and are exceedingly difficult to distinguish from one another, because two or more of them may frequently be found existing side by side in the same specimen. Three principal divisions are, however, supposed to include all the minor classes of poetry under general headings. These are lyrical, epical, and dramatic poetry. In the original sense all poetry was *Lyric*—that is to say, was composed to be sung to a musical accompaniment, and could not be conceived except in relation to some supposed accompaniment. In this work of song was divided into two parts, that which was regulated by the air, and that which was expressed in recitative. In the former manner were sung all the poems which were inspired by the passions, which reflected moods individual to the poet, or which were independent of the spirit in particular. In the second manner were chanted matters of narration, statements of fact, didactic, hortatory, and philosophical disquisition. The poems on an air remained lyrical poetry proper, and continued to be more or less fitted to be sung to a musical accompaniment. The poems in recitative became what is vaguely known as Epic poetry, with its attendant classes, the Satire, the Epistle, the Tale, and the Fable. From all these the musical accompaniment soon fell away. In some eastern countries, however, narrative poetry is still, when publicly recited, accompanied by a monotonous music on a stringed instrument.

Dramatic poetry has retained, in its principal branches of Tragedy and Comedy, still less of the singing quality than epic poetry. In many cases drama has thrown off the mask of the air; and in other respects is now included in the general category of poetry partly because of its traditional form, and partly because its imaginative character still links it to lyrical and epic work. The origin of *drama*, however, was wholly lyrical. It was out of the dithyrambical song in honour of Dionysus that tragedy sprang. The litany was chanted by a chorus that danced as it sang, and in the process of time a single personage began to break away from the chorus at intervals, and either to express aspirations of his own, or to narrate stories of the god, or to insinuate the occasion. The *Comedy* had a similar beginning, and by degrees not one but two and then many actors confronted the chorus and drew it into conversation. The development of this new form of poetry was very rapid; it gained variety and a recognised code of forms which has been adhered to with frequent exceptions in the tragedies of *Eschylus*, a body of ancient dramatic poetry still capable, as recent experiments have shown, of satisfying the demands of a modern playwright. Here the purely lyric element, in spite of the predominance of the chorus, is already minimised in favour of the development of personal action and character, so that the subsequent transition to the form of the most modern prose tragedy.
is really very unessential. All the principles of dramatic poetry may be comprised in an essay on the *Agamemnon*.

One of these elements, then, the Song, the Statement, and the Drama, all poetry that is not of a primitive nature is capable of being resolved. That which was primitive—and of this we have to conjecture more than we can prove—was probably Song alone. But, while we divide poetry into these three elements, it is not to be supposed that they form the same easy division of poetical literature. Here are found, indeed, the three great classes, but, as has been already said, they are constantly detected existing side by side in one and the same composition. The more elaborate the species of poetry the more likely are we to find upon analysis that the classes are confounded in it. In the Song we still preserve the simplest form of poem. This is a short piece in regular recurrent rhythm, expressing with the utmost conciseness a single enthusiastic and intense personal emotion, which it pours forth without deviation at a breath. When the spontaneous outburst is over the song naturally closes.

No other species of poetry is so simple as this. The Ode, which is often regarded not merely as a lofty form of lyric, but as the typical form par excellence, is not so long and elaborate to be sung spontaneously, it requires sung in the drama in calling to its aid a chorus and an antithesis of singers; upon epic by its excursions into narrative and didactic reflection. The ode, in which we include its innermost form the Elegy, remains, however, truly lyrical in its intention and singularly ill-fitted to be sung. It offers no musical variety, whereas its very beauties, and in particular those subtle harmonies which are secured by a proper attention to the structure of its quatrains and stanzas, would not merely gain nothing, but would lose much of their lyrical charm. In it we can imagine even the sonnet chanted to some simple conventional melody, unobtrusive enough not to conceal its intellectual beauties nor that vein of reflective and pensive narration which links it to the epic order; and we must confess that we regard the sonnet as essentially lyrical, notwithstanding its complexity and monotony. Not less than the song, the sonnet requires to consist of the spontaneous expression of a single intense emotion. Whatever is true of the sonnet is true of the other traditional forms, some of which, as, for instance, the Rondeau, approach the song more closely, while others, as, for example, the grandiose Chant Royal, take their place on the further side of the sonnet, between the ode and the latter.

If in the divisions of lyrical poetry we find the ode, the sonnet, and the couplet, the counterpart is still more true when we turn to a similar examination of epic and dramatic poetry. In the first case we possess an exquisite form, less successfully cultivated in England than in Italy, the Tera Rex, in which the epic and the lyriepic elements co-exist to an almost equal degree. Here it is impossible to say whether the art of narrative or the art of song predominates. Even in the pure epic neither the lyrical nor the dramatic element is omitted. Whenever a burst of enthusiasm or passion seizes the narrator, he passes without transition into lyric; whenever from describing his personages he proceeds to a record of their conversation, he suddenly transforms his epic into drama. Indeed, the rank of the various sections of the epic order of poetry may almost be determined by the opportunity they give for an admixture of the others. The Epistle is one of the least lyrical sections of all poetry; it may, however, yet contain an element of the drama. Satire, when it compures no admixture of narrative, is apt to fall very low in the poetic scale. If its passion be enthusiastic and genuine it may attain to a certain lyric afflatus; but there is little of the instinct of song in mere rage and disdain. Pure satire is a commonly solely by its very nature and is one of those species of literature which prove the necessity of giving to poetry a definition depending in the first instance not on its truth or beauty as a 'criticism of life,' but on its rhythmic structure.

Drama, as existing in modern Europe, has lost much of the external appearance of poetry. The distinction which admits a comedy in prose within the order of poetical literature and yet excludes a novel seems an arbitrary one. But it can be accounted for on traditional grounds. The novel has always best, from the days of the later Greeks, written in prose, and properly so, for it is independent of regulated form. Comedy, on the other hand, has but very lately, and still not completely, escaped from the bonds of verse. Rhythmic form is still largely used for tragedy, although the tendency in the construction of the spoken is more towards prose, with a restraint which adds to the reader's pleasure, but in a much less degree to the spectator's. In other divisions of dramatric literature verse and even rime are still essential. In Opera, which is a comedy so closely bound with a conventional species of drama, both are necessary; and Pastoral imperatively demands for its graceful convention the ornament of metre. Dialogue, a dramatic form, may be combined even with an epical species as a medium for giving information or exhortation. Hastyly looked at, however, drama appears in its modern aspects to be divorced more and more completely from the sister branches of poetry. It is therefore important to insist on the fact that the great poetical principle of unity in variety rules here as it does in those compositions which seem to be the more complex. To a certain extent, the element holding the parts of a drama together, balancing them, and supplying them with the necessary fire and harmony, the humblest play cannot maintain its existence. It is this more or less concealed, which it is the business of a 'director' to make familiar, which must always distinguish dramatic literature from the varieties of prose fiction. As long as it obeys these laws it holds its place in the order of poetry, although it may have abandoned its rhythmic shape. If it throws off these fortunate restraints it either perishes altogether or it becomes a mere variety of the prose novel.

In the incessant discussion which takes place as to the nature of poetry, the real aspect of the question is too frequently obscured by a confusion between Poetry, as a craft practised by artists, and the Poetical as a classing of compositions. The latter, which has been analysed with extraordinary minuteness by the Germans, and in particular by Goethe and by Hegel, is not necessarily combined with any of the external forms of poetical literature. This distinction, admirably laid down by Diotima in the *Symposium* of Plato, has been generally forgotten by those who have endeavoured to sentimentalise the art and to confuse our ideas of it by such vague and futile definitions as the well-known formula 'Poetry is impassioned truth.' It seems almost waste of words to point out that while the best poetry must be impassioned and must be true, in accordance with Aristotle's dictum that the superiority of poetry consists 'in its possessing a higher truth and a higher seriousness,' yet that no definition which confines itself to mortal
or sentimental attributes can be adequate to distinguish an art which consists of the making of a certain definite thing in a certain definite form.

In short, and in spite of the extreme unwillingness of the metaphysician to acknowledge it, we must admit the idea of the making of poetry cannot be divorced from the incident of 'making,' whether we call it with Wordsworth 'impassioned expression' or employ the broader and simpler word 'execution.' Until the passion and the truth are fused into actual speech, and until that speech takes a rhetorical form, those elements may be 'poetical' as well as 'true,' but they do not form poetry. None of the wild words of Mr Ruskin deserve an immortality of repudiation more thoroughly than the following phrase, which is always on the lips of those who write laxly and nebulously about the poetic art. 'No weight nor mass nor beauty of execution can outweigh one grain or fragment of thought,' says Mr Ruskin. If this were true, half of the noblest poetry in the world would cease to possess any value. Thought may and often does accompany the expression of the passion. But it is not equivalent to it in execution, in imagoes, inseparable in images. 'Execution,' poetry—Horace' (1474-1688). It has a value that is the unity of the artist.

It is desirable to define what is meant by 'execution,' for on this depends our whole conception of the practice of poetry as an art. It is not confined to the observance of the technical laws of this form of composition, to a correct and beautiful use of rhythm, of stanzaic form, of rhyme, and of that variety in unity in which the charm of verse consists. All this is part of poetical execution, and an extremely important part. In most cases it has been held true that an individual cannot be without it. In execution, as in the other fine arts, is the mechanical performance by which the effect desired is produced in the most perfect and most characteristic manner, so as in the happiest combination to illustrate the nature of the art itself and the individuality of the artist. As the medium in which the poet works is language, execution in his case is the arrangement of the best words in the best order, in the best order being, in all but a few anomalous cases, a rhetorical one. The technical laws of verse, however, deal only with the 'best order.' There remain, as a part of execution, 'the best words.' This section of the definition covers all the intellectual propriety, the moral passion, the verbal felicity, the inmost charms and graces, of which 'the best order' is but the vehicle. It is part of a poet's technical work, part of his business as a maker, to produce this manifold perfection of regulated language, and all these beauties of expression and feeling cannot be rudely divided from that execution of which they are an inherent feature. The bad poet may have the intellect of Locke or Newton, and still learn to write poetical negations of his verses that in poetry no weight nor mass of thought can outweigh one grain of executive skill. It would, nevertheless, be a grave error to insist so emphatically on the importance of the outward form of poetry as to encourage neglect of its inward character. In a definition of poetry it has been deemed needful to dwell here on the fact that it is primarily an art and subjected to definite laws. But, as Joubrant has said, 'the lyre is a winged instrument,' and the closest attention to its consecutive arrangement will not give us the quality of light if inspiration be lacking. The vivid pleasure produced by the best poetry is due in large measure to the merits of its execution—its music, the splendor of its images, the harmony and felicity of its arrangement of language. But there is something beyond and above this 'completing feeling of delight,' there is a spiritual emotion which is the spontaneous result of close attention to great poetry, and which is created in the soul only by verse that is of the highest value. This emotion is founded on the Aristotelian qualities of 'the highest truth' and 'the higher seriousness,' and is inseparable from, though not to be confounded with, the mere physical delight in lovely sounds and marshalled groups of images. In this exquisite passion of poetry there is something supernatural, which evades analysis. It combines the experience of the intellectual with the spiritual: it has been felt and witnessed into what has only been, and can only be, imagined. The literature of all countries and of all ages has proved that this subtle and divine emotion is produced in its most direct form by the art of language rhythmically arranged, and to this art is given the name of Poetry.

The prose fragment called the Poetics of Aristotle is the earliest and most important treatise on the art of poetry which has come down to us from antiquity. What is commonly known as Horace's 'Art of Poetry' gives us the vision of an admirable Latin writer on verse and on the poet. In 1527 Vida published his Latin poem, Ars Poetica, which exercised a great authority, and was by many students preferred to Horace. Of more modern interest is Scépeau's Poétique Libri Septem (1561). The first manual of modern Italian prosody was Girolamo Muzio's Arte Poetica (1551). In the English of Elizabeth we have three important treatises on the art. An Apology for Poetry (1593), by Sir Philip Sidney; A Discourse of English Poetry (1586), by W. Webbe; and The Art of English Poetry (1598), by George Puttenham. In France the first important treatise on the art of poetry was the Art Poétique (1604), by Vauquelin de la Fresnaye. Nicolas Boileau, 'the Lawyer of Parnassus,' wrote an Art Poétique. Among French works of the 18th century the most important was the Poétique de la Poésie Française (1749), by Olivier, and Réflexions sur la Poésie (1752), by Louis Racine. Dryden's Essay on Dramatic Poetry belongs to 1699. Among modern works must be cited that portion of Hegel's Aesthétique, 'Guide's History of English Rhymes (1838; new ed. 1882) remains the best authority on British prosody, while the Petit Traité de Poésie Française is greatly to be recommended.

GREEK.

Homer (about 900).
Alcæus (600-550 B.C.).
Sappho (680-570 B.C.).
Eschylus (525-461 B.C.).
Pindar (500-466 B.C.).
Sophocles (496-405 B.C.).
Euripides (480-400 B.C.).
Aristophanes (445-385 B.C.).
Menander (452-291 B.C.).

LATIN.

Tibullus (53-18 B.C.).
Horace (65-8 B.C.).
Ovid (43 B.C.-A.D. 17 or 18).
Lucan (9-59 A.D.).
Marcellus (101-41 A.D.).
Juvenal (35-137 A.D.).

ITALIAN.

Dante (1265-1321).
Petrarch (1304-74).
Boccaccio (1313-91).
Ariosto (1474-1533).
Tasso (1543-1595).
Goldoni (1707-93).
Alfieri (1749-1803).
Manzoni (1785-1873).
Leopardi (1798-1837).
Pogge (Aponos cataphractus), a small fish, not uncommon on British coasts, also known as Armed Bullhead, Lyre, Pluck, and Noble. It is related to the Bullhead (q.v.). The body, about 6 inches long, is encased by large scales; the head is very broad, and the mouth is very small. Notwithstanding its uncouth appearance, it is good to eat.

Poggenztorf, Johann Christian, a German physicist, was born at Hamburg, 29th December 1796. He studied pharmacy, chemistry, and physics, and was professor of Physics at Berlin from 1834 till 1862. He was a member of the Berlin Academy of Sciences. His chief discoveries were in connection with electricity and galvanism; he also invented a multiplying galvanometer for measuring the electro-chemical action of currents. From 1824 he edited the Annalen der Physik und Chemie, better known as Poggendorff's Annalen, an important organ for the history of the physical sciences. Besides helping Liebig and Wöhler to prepare the Wasserkocher (1837-51), he wrote Lebenslinien zu einer Geschichte der exakten Wissenschaften (1853), Biographisches-Literarisches Wörterbuch zur Geschichte der exakten Wissenschaften (2 vols. 1857-63), and Geschichte der Physik (1879). He died 24th January 1877.

Poggio Bracciolini, Gian Francesco, a famous humanist, was born in 1260 at Terranova in Florence. He studied Latin under John of Ravena, and Greek under Manuel Chrysoloras, and early gained the notice of the Florentine scholars for his skill in copying MSS. About 1492 he became a secretary to the Roman curia; but, though the offices he held were of small importance, he seems to have taken no interest whatever in the movement of church affairs, but to have been devoted heart and soul to the resuscitation of classical learning. In the course of his duties at the Lateran, he explored the Swiss and Swedish convents for MSS., and later in his wider travels to England and elsewhere he never lost sight of the dearest interest of his life. He was able to recover MSS. of Quintilian, Ammianus Marcellinus, Lucretius, Silius Italicus, Voltaire, and other Roman authors. About 1452 he retired to Florence, and next year succeeded Carlo Aretino as historiographer to the republic. Here he died in 1459. His works include Letters (best ed. by Tonelli, 3 vols. Flo. 1852-61); moral essays On Nobility, On the Ineffectuality of Princes (with an account of Age (he himself in 1455 took to wife a girl of eighteen), and the like; a rhetorical Latin History of Florence, in imitation of Livy; a series of unclean and unscrupulous polemical invectives against contemporaries, especially Filippo Strozzi and Valla; and a poor translation into Latin of Xenophon's Cyropaedia. But his most famous book is the Liber Facetiarum, a collection of humorous and not too decent stories and jests, written in fair Latin, and full of merry raffistry at the expense of the monks and secular clergy. The book has been studied in the study of the diffusion and development of folk-tales, and here Poggio takes a place with Straparola, Morlino, Bocaccio, Sacchetti, and Bandello, between the later contovers of who have borrowed or worked up their stories on the one hand, and such earlier storytellers as the Zoppa, the Disciplina Clericorum, the Aurea Legenda, the Gesta Romanorum, and the Fabliaux on the other. A good edition (Fr. trans. and text) is that of Isidore Lisieux (Paris, 1875).

Pounding (same root as Eng. pound), in the law of Scotland, means the seizing and selling of a debtor's goods under process of law, or under the warrant of a heritable security, in order to pay the debt. It is either real or personal. Real pounding is the attaching of goods or movables on the land over which some heritable security exists. It is one mode in which heritable security is made efficacious. "The sheriff shall serve the warrant of him that is pounder to the land, to obtain payment of his feu-duities; and the holder of a heritable bond can do the same in order to recover his debt. Personal pounding is the mode in which a decree of the court is made efficacious by the messenger or bailiff seizing the movables of the debtor. In 1839 he was empowered to a debtor has been charged to pay the debt and the days of charge have elapsed. The debtor's
POINSETTIA

POISON

goods being pointed, they are appraised or valued, and the messenger reports his execution to the sheriff, or other judge ordinary, who grants warrant to sell the goods by public rump after advertisements. The net amount of the sale is paid over to the creditor in payment for them, they are delivered to the creditor at the appraised value. There is also another kind of pointing, called a pointing of stray cattle, which takes place whenever the cattle of a stranger trespass on lands, in which case the owner or occupier of the lands can seize them at his own hand, without judicial warrant, and keep them as a security until the damage done by the cattle is paid to the owner of the land. The pointer must, however, take care to keep the cattle in a proper place, and feed them. In England the word pointing is not used, the corresponding term being Distress (q.v.).

POINSETTIA. a name given to the Mexican shrub 

Euphorbia pulcherrima, introduced into the horticulture of other lands by Joel Roberts Poinsett (1779–1851), U.S. minister to Mexico. It is remarkable for the large and conspicuous vermilion bracts below its yellowish flowers.

POINSETTIA-Plire, the principal town and port, though not the capital, of Guadeloupe (q.v.), on the south-west side of Grande-Terre. It is fortified, and has some sugar-boiling. Pop. 17,000.

Point de Galle. See GALLE.

Pointed Architecture. See GOTHIC.

POINTER. a breed introduced from Spain about the middle of the 18th century. The Spanish pointer was a larger and much slower dog than the modern English pointer, rather wanting in stamina, and inclined to "knock up" with a hard day's work; but, if not hurried, was possessed of wonderful nose and powers of scent. As shooting became more common, and guns approached nearer to perfection, the Spanish pointer was found to be too slow and soft. With the object of removing these defects, crosses with the greyhound to improve the speed, and with the bulldog to get courage, were tried, but with little success, until about the beginning of the 19th century the well-known Colonel Thornton tried a cross with the lighter variety of foxhound. He soon succeeded in breeding a light and active dog, capable of ranging at a fast pace for a considerable time, and though possibly not with the nose of the old Spanish pointer, yet with sufficient for the purpose. Other breeders followed suit, and a distinct strain known as the English Pointer was soon established. By careful selection the hound tendency to hunt a foot-scent was eradicated, or nearly so, while some of the speed and staying powers of the hound were retained. The act of "pointing" when the game is first scented was at first carefully taught, but gradually became instinctive, until now well-bred puppies of a few months old may be seen pointing at any object which excites them. In general appearance the pointer somewhat resembles the foxhound, though he is a lighter and more active dog, with a finer coat. The head of the pointer should be rounder, broader, and longer than that of the foxhound, with an intelligent expression; a small eye or too much lip greatly detracts from the appearance. The shoulders should be sloping and powerful, as the dog has often to stop suddenly on a "point" when at full speed. The body should be built on graceful and strong lines, chest not too wide, but very deep, feet round and compact. Liver and white, and lemon and white, are the popular colours, as they are easily seen in heather or turnips, but whole black or liver has many admirers. Owing to the changed conditions of agriculture, the pointer is not now made an extensiy for pheasant shooting, but is still used for grouse. In hot weather, where water is scarce, the pointer has a great advantage over the setter, but succumbs sooner to cold and wet than the heavy coated setter. As the pointer is seldom kept as a companion, his intelligence is not of a high order, but he is easily kept in command, and is generally good tempered.

POISON is commonly defined to be a substance which, when administered in small quantity, is capable of acting deleteriously on the body; but this definition is obviously too restricted, for it would exclude numerous substances which are only poisons when administered in large doses, as the salts of lead, antimony, &c.; hence the quantity required to kill must not enter into the definition. A good practical definition of a poison is "any substance or matter which, when introduced into the body in any way, can destroy life by its own inherent qualities without acting mechanically."

This definition includes poisonsos solids, liquids, and gases of definite chemical composition—the products of decomposition or of bacterial organisms, and the virus of contagious diseases. The last mentioned produce the symptoms of the various infectious and contagious diseases and are not included in treatises on poisons. The others are classified sometimes according to their source, as mineral, vegetable, and animal; or more conveniently according to their action, as Irritants, Narcotic-irritants, Corrosive-irritants, Corrosive, and so forth.

The Irritants, when taken in ordinary doses, speedily occasion intense vomiting and purging and severe abdominal pain. They act chiefly on the stomach and intestines, which they irritate, inflame, and frequently corrode, and may thus occasion inflammation, perforation.

Amongst those which possess corrosive properties are the strong mineral acids, caustic alkalies, corrosive sublimate, &c.; whilst among the pure irritants which exert no destructive chemical action on the tissues with which they come in contact may be mentioned cantharides. The Narcotic-irritants act specially on the brain and spinal cord. Amongst their most common symptoms are giddiness, headache, obscurity of sight or double vision, stupor, loss of power of the voluntary muscles, convulsions, and, finally, complete coma. These poisons have an acrid, burning taste, nor do they usually give rise to vomiting or diarrhoea, and, excepting a slight fulness of the cerebral vessels, they leave no well-marked post-mortem appearance. They are few in number, and none of them belong to the mineral kingdom. The Narcotic-irritants have, as a rule, certain impulse effects of varying periods after they have been swallowed they give rise to vomiting and purging, like irritants, and sooner or later produce stupor, coma, paralysis, and convulsions, owing to their effect on the brain and spinal marrow. As familiar examples we may
point to monkshood, tobacco, and poisonous mush-
rooms. Sometimes the more violent of the poisons
here classed as irritants are made into a separate
group—Corrohle;s; the neroitics are put under the
head Neartities; and the gaseous poisons are treated
as a separate class.

Under the head of Irritant Poisons may be included
(1) Mineral Acids, as sulphuretted, nitric, and
hydrochloric acids; vegetable acids, and some of
their salts, oxide of carbon (hence potash), tartaric
acid, and tartaric acid (in doses of half an ounce or
more); the alkalies, as pearl-ash (carbonate of potash),
soda, and carbonates of lime; common salt, and
pearlash (sodium pernitrate), as well as carbonate
of potash; (2) Vegetable Substances—viz. colo-cynth
and gamboge in large doses, savin, croton-oil,
elaterum, &c.; and (3) Animal Substances, such as
cantharides, to which must be added the occasional
cases in which sausages, and certain fish and
molluscs, usually quite innocuous, act as irritant poisons.
The Narcotic Poisons include opium, hydrocyanic (or prussic
acid), cyanide of potassium, hemoglobin, alcohol, ether,
chloroform, and chloroform. The Narcotic-irritant Poisons
include nux vomica, meadow saffron (Crocus sativus), white
hemlock, the common rue, spikenard, garlic, belladonna,
water hemlock, hemlock water-dropwort (Eunicea crocata),
fool's parsley, thorn-apple, monkshood oraconite, deadly nightshade,
tobacco, Indian tobacco (Lobelia inflata), the bark and
seeds of the common laburnum, the berries and leaves
of the yew-tree, and certain kinds of fungi.
The cases in which there are antidotes qualified
to neutralise chemically the action of the poison are
few in number. For the mineral acids chalk
or magnesia in water must be used, with the
vomiting fluid; bichloride of mercury should be
given freely. The alkalies and their carbonates
must be neutralised by vinegar and water; or lemon-
juce mixed with water, after which milk should be
given. For oxalic acid the antidote is chalk or
magnesia in water, by which an insoluble oxalate
of lime or magnesium is formed. For arsenic the
hydrated peroxide of iron has been regarded as
an antidote, but its efficacy is doubtful. Vomiting
should be excited by the administration of a scruple
of sulphate of zinc in warm water, and, after the
stomach has been well cleared out, demulcent fluids,
such as flour and water or milk, should be given.
Corrosive sublimate combines with albumen (white
of egg), and forms an insoluble inert mass; nitrate
of silver is neutralised by chloride of sodium (com-
mon salt) dissolved in water; tartarated antimony
is neutralised by the administration of decoction
of bark or gall-nuts; and acetate of lead is rendered inert by the administra-
tion of sulphate of magnesia, which converts it into
an insoluble sulphate of lead. In all cases of sus-
pected poisoning, in which the poison is of
unknown nature, the safest course is at once to produce
vomiting by sulphate of zinc, or in its absence by
a dessert-spoonful of flour of mustard suspended in
tepid water, and to continue the vomiting till all
the contents of the stomach are discharged, after
which milk should be given freely.

Most of the known gases have a poisonous action
when inhaled into the lungs; in these cases death
may be due simply to suffocation or to a specific
toxic action of the gas. In cases of poisoning by
smoke, or fume, or by gases, the remedies are
seldom employed as an instrument of self-destruction.
It is established by numerous experiments that air con-
taining more than one-tenth of its volume of car-
bonic oxide, deserves to be considered as a death
of higher animals; when diluted with two or more
volumes of air it can be breathed, and produces
symptoms of vertigo and somnolency, and so great
a loss of muscular power that the individual, if in
an erect or sitting position, falls as if struck to
the ground. The respiration, which at first is difficult
and stertorous, becomes suspended. The action of
the heart is at first violent, but soon ceases, sensi-
bility is lost, and the person now falls into a coma-
tose or death-like state. Those who have been
asphyxiated usually feel pain in the head, and
the general soreness of the body for some days, and in
a few severe cases paralysis of the muscles of the
face has remained. The patient must, of course,
be at once removed from the poisonous atmosphere,
after which artificial respiration should be had
for and continued; poison may be poured on the head and spine; while if the
surface be cold a warm bath should be employed.
When respiration is re-established venesection
will often relieve the congestion of the vessels of the
brain. The inhalation of oxygen gas is said to have been of service in these cases. Carbonic oxide
is also an active poison, and is present in coal-gas
and in charcoal furnaces. Both carbonic acid
and carbonic oxide act as powerful narcotics. The fatal
power of ordinary coal-gas as an asphyxiant and irri-
tant is probably due to the carbonic oxide present;
the post-mortem appearances of the organs in cases of poisoning by coal-gas and by carbonic oxide.
Sulphurated hydrogen, which occurs abund-
antly in foul drains, sewers, cesspools, &c., is a
gaseous poison whose effects are often noticed.
Nothing certain is known of the smallest propor-
tion of this gas required to destroy human life;
but air containing only \( \frac{1}{1000} \) of its volume of this
gas will destroy a dog; and when the gas exists in
the proportion of \( \frac{1}{100} \) it will kill a horse.
During the construction of the Thames Tunnel
death occurred from the men employed in the work,
shut up from the presence of this gas, which was probably
derived from the action of the water on the iron
pyrites in the clay, and which issued in sudden
bursts from the walls. By respiring this atmosphere
the strongest and most robust men were in the
course of a few months reduced to an extreme state
of exhaustion, and several died. The symptoms
with which they were first affected were giddiness,
sickness, and general debility; they became ema-
ciated, and fell into a state of low fever accompanied
by delirium. In this case the dilution was extreme;
when the gas is breathed in a more concentrated
form the person speedily falls, apparently lifeless.
It appears to act as a narcotic poison when concen-
trated, but like a narcotic-irritant when much
diluted with air. The action of the vapour of
sulphide of carbon is somewhat similar, and frequently
present in cesspools, &c., is probably much the
same as that of sulphurated hydrogen. Many of
the gases which are only found as products of the
laboratory are in the highest degree poisons, as
arseniated hydrogen; many are only poisonous
in the presence of some little amount of
risk of inspiring them it is unnecessary to enter
into details.

In point of Law, the use of poison to kill or
injure a human being or certain animals renders
the poisoner amenable to the criminal courts. With
regard to the sale of poisons, the legislature found
it necessary to put some restrictions on one description—viz. arsenic—in order to prevent persons obtaining it with facility, and in such a manner as to avoid the possibility of their being used for the purposes of poisoning. The act requires every person who sells arsenic to enter in his books the date and quantity and purpose of its use, and later acts apply this rule to other poisons. It is not to be sold to one who is unknown to the vendor unless in presence of a witness who is known, and whose place of abode is recorded in the book. The arsenic must also be mixed with soot or indigo, in the proportion of 4 oz. of soot or indigo to the lb. All the boxes, bottles, &c. must be labelled 'Poison.' Those who offend as to arsenic incur a penalty of £50; but in ordinary prescriptions poisons may be used without incurring the view of detection. As to the restriction on the sale of other poisons, see Chemists and Druggists. The offences committed by those who administer poisons to mankind are as follows: Whoever causes death by poison commits murder, for the means are immaterial if the death was caused by such means with a felonious intent. Where death is not caused, nevertheless whoever administers poison, or causes it to be administered to any person, with intent to commit murder is guilty of felony, and is liable to penal servitude for life, or for any number of years, whoever attempts to administer poison, or other destructive thing, to any person with intent to commit murder is guilty of felony, and is punishable in the same way. These offences are committed whether the poison administered or attempted to be administered, does injury or not; and it is a sufficient con- mitting of the offence if the poison is put in such a place that a party was likely, and was intended to take it. Moreover, even though murder was not intended, but merely an intent to endanger life or inflict grievous bodily harm, still the offence is felony, and is punishable by penal servitude varying from three to ten years. There is also a similar punishment for the attempt to administer any stupe- fying drug. Not only is it a crime to administer or attempt to administer poison to human beings, but if cattle are maliciously killed by poison the offender is punishable by penal servitude from three to fourteen years. So to kill by poison any dog, bird, beast, or other animal, ordinarily kept in a state of confinement, is an offence pun-ishable by justices of the peace with imprisonment for six months, or a fine of £20 over and above the injury done by the poison. Any person on land who kill game he incurs a penalty of £10. Moreover, by the Act 26 and 27 Vict. chap. 113, extending to the United Kingdom, whoever sells or offers to sell poisoned grain, seed, or meal incurs a penalty of £10. Whoever sows, lays, or puts on ground such poisoned grain incurs a like penalty. The use of poisoned flesh is also prohibited. But the sale or use of any solution, material, or ingredient for dressing, protecting, or preparing any grain or seed for agricultural use only, if used bonâ fide, is not interfered with.

Secret Poisoning is a mode of taking away life by poisons so slow in their operation that the gradual sinking of the victims under their influence closely resembled the effects of disease or the ordinary decay of nature. It has been practised in all ages, and several undoubted and numerous supposed instances are reported by ancient and modern writers. The prevailing ignorance of pathology and chemistry enabled crimes to be carried out with impunity with poisons which would be readily detected at the present day; and for similar reasons many deaths were ascribed to poison that were doubtless due to natural causes. It is im- possible to attach much credence to stories such as that Henry VI. was killed by a pair of poisoned gloves, or that victims were simply got rid of by inducing them to smell a poisoned rose. And it is wholly incredible that in pre-scientific days treach- eros and secret and mysterious methods of poisoning beyond the power of detection that are happily denied to scientific investigators in days when we are ac- quainted with ten times as many and ten times as subtle poisons. In secret poisoning various preparations of arsenic seem once to have been most frequently used. In the 17th century this atrocious practice became of specially frequent oc- currence; and from this time it rapidly increased, spread over western Europe like an epidemic, and became gradually a regular branch of edu- cation, and the profession of so-called medical men of science, or those who afterwards pretended to heal disease by science, chemistry, magic, or astrology. These persons regarded the knowledge of the mode of prepar- ing secret poisons as of the highest importance, and many of them realised large sums by the sale of their preparations, and occasionally of the secret of their composition. It was in Italy and France that this art was chiefly practised and brought to the highest perfection; but it seems also to have prevailed in England to a considerable extent, for in 1531 the poisoning of seventeen per- sons, two of whom died, by the Bishop of Rochester's chef de cuisine was one instance of the employment of secret poisons to be high-treason, and sentenced those who were found guilty of it to be boiled to death. This act was repealed in 1547.

The only undoubted instance of this crime which appears prominently in English history is the murder of Sir Thomas Overbury (q.v.) by Viscount Chester (the favourite minion of James I.) and his wife, the divorced Countess of Essex. Prince Henry was falsely supposed to have been poisoned by his father, James I. (1612); and James's own death was similarly ascribed to nefarious practices on the part of Buckingham, nay, even of Charles I. (Milton). Undoubtedly such was the popular impression at the time, for Dr Lamb, a conjurer and quack, who was believed to have furnished Buckingham with the poisons, died at the age of three months, and his body was found in a wooden box, which was thrown into Wood Street, Cheapside, London, and beheaded and stoned to death. But it was in Italy that this mode of poisoning was most prevalent. There, judging from the writings of various authors, it seems to have been looked upon as a not unjustifi- able and approved practice of poisoning by poison; and from the time of the Lombard invasion down to the 17th century Italian history teems with instances which sufficiently show that poison was both the favourite weapon of the oppressor and the protection or revenge of the oppressed. The Borgias (q.v.) are generally singled out and held up to the horror and detestation of mankind; but as far as their poisonings are concerned they merely employed this method of destroying their adver- saries a little more frequently than their neigh- bours. To show the popular feeling on this subject was this custom and practice that is mentioned in the Mémoires of Henry II., fifth Duke of Guise, of a soldier who was requested to rid the Duke of Gennaro Annese, one of his opponents in Naples. Assassination was the mode proposed to the soldier, but he 'shrank with horror from the suggestion, and declared that the Duke and Rome were safe from poison Annese.' It was shortly after the date of this story (1648) that secret poisonning became so frequent; and the Catholic clergy, despite the rules of the confessional, felt themselves bound to acquit Pope Alexander VII. with the extent of the practice. On investigation it was found that young widows were extraordinarily abundant in Rome, and that most of the unhappy marriages
were speedily dissolved by the sickness and death of the husband; and further inquiries resulted in the discovery of a scoundrel, scaldy young, of whom, which met at the house of an old bag, by name Hieronyma Spara, a reputed witch and fortune-teller, who supplied those of them who wished to resent the infidelities of their husbands with a slow poison, clear, tasteless, and insipid, and of strength such as made them take the victim at a week, month, or number of months, as the purchaser preferred. The ladies of Rome had been long acquainted with the 'wonderful elixir' compounded by La Spara; but they kept the secret so well, and made each effectual use of their knowledge after several years, during which a large number of unsuspected victims had perished, and even then through a cunning artefact of the police, that the whole proceedings were brought to light. La Spara and thirteen of her companions were hanged, a large number of the culprits were whipped half-naked through the streets of Rome, and some of the highest rank suffered fines and banishment. About half a century afterwards the discovery was made of a similar organisation at Naples, headed by an old woman named 'Frenchman Mary,' who manufactured and sold it under the name of concocted and sold it extensively in Naples under the name of acqua, and even sent it to all parts of Italy under the name of Mania of St Nicola of Bari, giving it the same name as the renowned medicine of all ages, aqua vitae, but a poison. This poison, now best known as the 'Aqua Tofana' or 'Aqua di Perugia,' is said to have been compounded of arsenical neutral salts; while Garrelli states that it was crystallised arsenic dissolved in a large quantity of water; but both of these products were prepared indubitably, and speedily by gradually weakening the appetite and digestive organs. After having directly or indirectly caused the death of more than 600 persons, Tofanile was at length seized, tried, and executed in 1722. From this time the mania for secret poisoning gradually died away in Italy.

Catharine de Medici has been frequently charged with wholesale poisoning, and in 1588 four of the Scottish commissioners who had been present at Queen Mary's marriage to the Dauphin were sentenced to death as poisoners. But the poisoning in question was about the middle of the 17th century that this horrible practice seems to have become most prevalent in France. Here, too, the agents were married women, and their husbands the victims; and, as in Italy, the extent to which the practice was carried was first made known by the clergy. The government, acting on the information thus obtained, seized and imprisoned in the Bastille two Italians named Exil and Glaser, who were suspected of having been the manufacturers and venders of the poisons. Glaser died in prison, but Exil, becoming acquainted with another prisoner named St Croix, communicated to him his secret, which the latter made considerable use of after his release, compounding in particular the poison known as 'succession powder,' which subsequently became the more usual name of it. It was the same St Croix who played such a prominent part in the tragic history of the Marquis de Brinvilles (q.v.). Penautier, the treasurer of the province of Languedoc, and the Cardinal de Bonsy were both pupils of St Croix, and managed, the one to pave the way for his own advancement, and the other to rid himself of his numerous creditors by the administration of poison; but the great influence of these men and the want of direct evidence barred all proceedings against them. Secret poisoning now became fashionable; the passions of jealousy, revenge, avarice, and even petty spite were all satisfied in the same way, and as a necessary consequence other offences decreased in proportion. The prisons filled with suspected criminals, and the 'Chambre Ardente' was instituted for the special purpose of trying these offenders. In Paris this trade was chiefly in the hands of two women named Lavoisin and Lavigreux, who combined with the ostensible occupa- tion of midwife the celebration of masses to wives the decease of their husbands, to neely heins that of their rich relatives, taking care at the same time to be instrumental in fulfilling their own predictions. Their houses were frequented by numbers of all classes, both from Paris and the provinces; every little celebrity, the celebrated Marshal de Luxembourg (q.v.), the Dukes of Bouillon, and the Comte de Soissons; the two former of these, however, went merely from curiosity. Lavoisin and her confederate were at last discovered, tried, condemned, and burned alive in the Place de Cité; 22d May 1680. The poisoners employed in this manner were hung in various cities of France. So common had this atrocious practice been that Madame de Sévigné, in one of her letters, expresses a fear lest the terms 'poison' and 'poisoner' should become synonymous. For two years after the execution of the two Parisian poisoners the crime continued to be largely committed, being fostered by the impunity with which offenders of high rank were allowed to escape; and it was not till more than a hundred persons had been tried and the state of these trials that the government succeeded in suppressing it. The mania for secret poisoning has not since been revived to the same extent, though isolated instances of its practice have occasionally been discovered, particularly in Hungary, where, within the last half of the 19th century, very extraordinary disclosures have at different times been made of the prevalence of this frightful crime among the peasant women. During the times of slavery the Obeah men among the negroes in the West Indies were credited with being expert poisoners. They used vegetable poisons obtained from plants, and there can be no doubt were often instrumental in getting rid of tyrannical or otherwise objectionable masters. In Britain famous poisoning trials have been those of W. Palmer (1885); of Bites (1870); of Taylor (1879); of Croix (1885); of Pritchard, M.D. (two victims, 1865); of Mary Ann Cotton (sixteen victims, 1872); of G. H. Lamson, M.D. (1882); of Cross, M.D. (1887); and Mrs Maybrick (1889). See the articles on ADULTERATION, ASPHYXIANTS, NARCOTICS, DISSECTION, WOUNDS, LEAD-POISONING, PYRAMEI, PITOMINATE, SNAKES, VENOMOUS BITES, WOUNDS; the classification of diseases at DISEASE; for poisoned arrows, ARCHERY and CURAR; for the more important poisons and their treatment, ACID, ARSENIC, HYDROCHLORIC ACID, STARCHINE, UPHAR, &c.; for toxic and anti-toxic methods, and theories therein involved, GERM, BACTERIA, DIPHTHERIA, HYDROPHOBIA, TETANUS, TUBERCULOSIS, and the measures taken for their prevention; and works on toxicology by Christison (1829), Taylor (1847); 2d ed. 1875), Reese (1874), Wormley (1867, 2d ed. 1875), A. Winter Blyth (1883); 2d ed. 1886); and J. D. Mann (1836).—For the Poison Ivy, see SACHUR.

Poison, Simeon-Denis, was born at Pithiviers, in Loiret, 21st June 1781; and received into the École Polytechnique in 1798, attracted the notice of Lagrange and Laplace, and was appointed for him a brilliant career. In 1802 he became a professor in the Polytechnic; in 1808 a member of the Bureau des Longitudes; in 1809 professor in the Faculty of Sciences; member of the Institute in 1812, &c.; and this list of distinctions was crowned in 1837 by his elevation to the dignity of a peer of France. He died 25th April 1840. Poison's
whole life was devoted to the prosecution of scientific research, and the fruits of his pen number about 300 publications, including 30 books. Poisson was a professor of the Ecole Polytechnique, of the Academy of Sciences, and other scientific journals. Of the separate treatises published by Poisson the best known is the Traité de Mécanique (2 vols. 1833); others were on capillary action, the mathematical calculus of probabilities, and the mathematical theories of heat, and, lastly, the celebrated work Sur l'Invarianibilité des moyens Mouvements des grands Axes Planetaires.

Poitiers, the capital of the French department of Vienne, occupies the summit and slopes of a little eminence, round which once flowed the Clairs and the Beivre, 61 miles SSW. of Tours. Before the revolution it had an immense number of religious edifices, which even yet are sufficiently numerous. The most interesting are the little Temple de St Jean, originally a baptistery of the 6th or 7th century; the abbey church of St Radegonde, with the same name of the pilgrims; and the noble cathedral of St Pierre (1161-15th century), in which, or in the older edifice that occupied its site, twenty-three councils were held—the first in the 4th, and the last in the 15th century. Other edifices are the Palais-de-Justice (the palace formerly of the Counts of Poitou) and the Hôtel-de-Ville (1876). A university, founded by Charles VII. in 1431, is now represented by a school of law, with faculties also of science and literature. There are besides a public library of 30,000 volumes and 400 MSS., a museum, and several learned societies, including one for studying the antiquities of western France (1834). Pop. (1872) 28,247; (1891) 37,497. Poitiers, the Limousin of the Romans, derivatives its present name (earlier Poictiers) from the Pictavi or Pictones. In and around it are numerous Celtic and Roman remains, a dolmen, baths, some fragments of a huge amphitheatre, &c.; and here in 1882 the remains of a whole Gallo-Roman town were discovered, with temple, baths, and streets, spread over 14 acres. In the vicinity Alaric II., the Visigoth, was defeated and slain by Clovis in 507; and southwest of Poitiers the famous Wars Charles Martel won his great victory in 732 over the Saracens under Abd-ar-Rahman. Later still (on 19th September 1356), at a spot 5 miles north of Poitiers, Edward the Black Prince, with some 12,000 or 14,000 Englishmen and Gascons, defeated the army of the troops of King John of France, killing 11,000 and taking more than 2000 prisoners, among those the monarch himself and one of his sons. St Hilary (q.v.) was the first bishop of Poitiers, which long was capital of the province of Poitou. From this town the ancient family took its name to which Diana of Poitiers (q.v.) belonged.

Poitou, a former province of south-western France, coincident with the present departments of Deux Sèvres, Vendée, and Vienne. It was divided into Upper and Lower Poitou, and had for its capital Poitiers. Its early history is the same as that of Aquitania (q.v.). Poitou became a possession of the English crown when Eleanor, Countess of Poitou and Duchess of Aquitaine, married (1152) Henry of Anjou (see Henry II.). Philip Augustus reconquered it in 1205. In 1399 it reverted to England, but nine years later was retaken by Charles V. See Aubr, Histoire de Poitou (1880-88).

Poke (Phytolaca americana), an American bracteate racemose, white flowers and deep-purple berries (Inkberries or Pigeonberries). See also HELLEBORE.

Poker, a round game at cards (developed from the older game of brag). Each player has five cards
dealt him. A sum called the ante is deposited by the oldest hand. The players then look at their hands. The round may then begin. If the player to the left of the dealer chooses not to play, his opponent may do so, if he will play or pass. If he passes he throws down his cards and stakes nothing. If he plays he has to chip to fill—i.e. to stake a sum equal to twice the ante; the amount chipped by the ante, if he plays, or makes good the ante, is only equal to his first stake. Each player's contention may then discontinue any of his cards and receive from the dealer an equal number of cards from the top of the pack, but no one is obliged to discard any. When all have filled, each player in order must either raise his stake or go out of the game, forfeiting what he has chipped. The raising generally is limited, but any less sum than the limit is to be considered. Subsequent players must either see the raise—i.e. make the sum next staked equal to that of the last raiser—or go before—i.e. raise higher, or go out of the game. The raising, seeing, going better, or going out, as the case may be, continues until either all the players but one have got out (when the one left in takes the pool), or until all the stakes of the players left in are equal, no one going better. Then a call is declared. The player to the left of the one who calls takes the pool. He has then a new hand, and the best combination he holds which has a poker value. The subsequent players in order either show anything they have better, or throw down their hands. The best poker hand takes the pool.

In case of absolute equality the pool is divided. The value of the hands is as follows, beginning with the best: (1) Straight flush, sequence of five cards of the same suit; (2) Fours, four cards of the same rank, accompanied by any other card; (3) Full, three cards of the same rank, and a pair; (4) Flush, five cards of the same suit, not in sequence; (5) Straight, any five cards in sequence; (6) Triplets, three cards of the same rank, not accompanied by a pair; (7) Two pairs; (8) One pair; (9) Highest card. The cards rank as at whist (ace highest), except in the case of straightflushes, when ace may be highest or lowest—i.e. ace, king, queen, knave, ten, or five, four, three, two, ace form the highest and lowest straights respectively. If more than one player holds a straight flush the sequence headed by the highest card wins; the same as between two straights. Similarly, the highest fours win, the highest triplets in triplet hands; in the case of fulls, the highest holds the highest wins. As between two flushes, the highest card wins; if these tie, the next highest, and so on. If two players each hold two pairs, the highest pair wins; if the two pairs tie, the remaining highest card wins; with one pair, the same. If none of the players remaining in the game hold any of the above combinations, each shows his highest card; if there is a tie, the next highest, and so on. There are numerous varieties in the way of playing, for which treatises on poker should be consulted. The above describes the simplest form of Draw Poker, the game most commonly played. See books by Keller (New York, 1887) and Guerndale (1889).

Poker-drawings, the name given to designs (after well-known pictures generally) burnt into lime-tree or other wood with 'pokers,' which rather resemble plumbers' tools. The name is chiefly applied to 'poker,' 'pyrotechnic,' or 'pyrographic' artists were John Cranch (1751-1823), Smith of Skipton, and Dr Griffiths, the master of University College, for whose chapel he executed an altar-piece for Carlo Dolce. At Knole are two poker-drawings ascribed to Salvador Rosso. A similar process of adorning ships' cabins, table-tops, &c., was patented in 1865.
Polish (Polski), a town of India, in the Rajput state of Jodhpur, 70 miles NW. of Jodhpur.

Poland, the most important naval station of Austria-Hungary, is situated near the southern extremity of the peninsula of ISTRIA, 105 miles by rail S. of Trieste. The harbour is thoroughly sheltered, deep, and spacious enough to accommodate the largest fleet. The town is protected by a fortified belt, and is overlooked by the citadel, by which it and the bay are commanded. The arsenal employs about 2400 men. There are also artillery and powder stores, docks, slips, &c.

The cathedral dates from the 15th century. Pola is also a shipping port, exporting wood, fish, sand, and building timber, and importing wine, canvas, and bricks. Pop. (1850) 27,173; (1890) 39,273, of whom 10,000 belonged to the garrison. Founded traditionally by the Colchians who were sent in pursuit of Jason, Pola was destroyed by Augustus, but rebuilt at the request of his daughter Julia, on which account it was named Piaetas Julia. At the beginning of the 3d century it had 30,000 inhabitants, and was a station of the Roman fleet. It was destroyed in 1297 by its Venetian masters, who had conquered it in 1148, and afterwards ruledit for 257 years. After routing the Venetians in see fight off the town, once more ravaged it. But it only passed from Venice in 1797 to Austria, who chose it as her chief naval harbour in 1848. It contains numerous interesting Roman remains, among them a well-preserved amphitheatre, 450 feet long and 360 broad. A temple and several ancient gates are also extant. See Allison's Antiquities of Pola (Lond. 1819), and Jackson's Dalmatia, the Quarnaro, and Istria (1887).

Polabians, an ancient Slavic race, belonging to the same group as the Poles, occupying the country of the Leve Elbe. They have long been Germanised, and their language is now extinct. The term is sometimes used in a wider sense for all Slavonic peoples west and north-west of the Oder and the Erzgebirge. See Slavs.

Pola, a species of vessel in use in the Mediterranean and Indian seas, with jib-lugs; the fore- and main-masts being of one piece ("pole-masts"), and the mizen-mast with a top and topmast.

Pola. See Poloaise.

Poland (called by the natives Polski, a word of the same root as Pole, "a plain"), a former kingdom of Europe, was, immediately previous to its dismemberment, bounded on the N. by the Baltic Sea from Danzig to Riga, and by the Russian provinces of Pskov and Pskov; on the E. by the Russian provinces of Smolensk, Ternopol, and Kharson; on the S. by Bessarabia, Moldavia, and the Carpathian Mountains; and on the W. by the Prussian provinces of Silesia, Brandenburg, and Pomerania. Its greatest length from north to south was 713 English miles, and from east to west 693 miles, embracing an area of about 292,000 English sq. m. (40,000 larger than Austria-Hungary is now); an area which in 1890 had a population of 24,000,000. This extensive tract forms part of the great European central plain, and is crossed by only one range of hills, which rise from the north side of the Carpathians and run north-east through the country, forming the watershed between the rivers which flow into the Baltic and Black Sea. The soil is mostly a light fertile loam, well adapted for cereals, though here and there occur extensive barren tracts of sand, heath, and swamp, especially in the eastern districts. Much of the fertile soil is rich pasture-land, and much is occupied with forests of pine, birch, oak, &c. Rye, wheat, barley, and other cereals, hemp, timber, honey and wax, cattle, sheep, and hogs, vast mines of salt; and a little silver, iron, copper, and lead constitute the natural riches of the country; and for the purposes of commerce the Vistula, Dnieper, Dvina, and their tributaries afford great facilities.

The kingdom of Poland, during the period of its greatest extent, after the abolition of the grand-duchy of Lithuania at the close of the 14th century, was subdivided, for purposes of government, into about forty palatines (Pol. województwa), which were mostly governed by hereditary chieftains. The people were divided into two great classes—nobles and serfs. The nobility was divided into two classes, to which were the privileged and governing classes, included the higher nobles, the inferior nobles (a numerous class, corresponding to the knights and gentry of other countries), and the clergy, and numbered in all 200,000; the serfs formed the agricultural labourers, and were attached to the soil. Their condition is described by all travellers as a very pitiable one. Such trade as the country had was mostly in the hands of the Germans and Jews. The nobles were the proprietors of the soil, and appropriated the larger portion of its products, the serfs being left with a bare subsistence. The system was calculated, and hospitable, but quarrelsome, and generally preferred their own interests to that of their country; the serfs (originally called Knize; Lat. Knieten) were sunk in poverty and ignorance, and the present system is that of the old. In the Poland of former days consists of Poles, Lithuanians, Germans, Jews, Malo-Russians, Romanians, Gypsies, &c. The Poles, who number 10,000,000, form the bulk of the population; the Lithuanians, 2,400,000 in number, inhabit the north-eastern part of the country; the Germans, numbering more than 2,000,000, live mostly in the towns; the Jews are very numerous, being reckoned at 2,200,000. Of Roman Catholics there are about 9,400,000; of members of the Greek Church (including Uniates), 7,900,000; of Protestants, 2,300,000; the rest are Jews, Armenians in Galicia, &c.

History,—The Poles are ethnologically a branch of the Slavs (q.v.). The name appears first in history as the designation of a tribe, the Poliani, who dwelt beyond the Oder and the Vistula, being surrounded by the kindred tribes of the Masovii, Kujavi, Chrobates, Silesians, Obotrites, and others. In course of time the name Polani became pre-dominant. There is no real Polish history till the reign of Mieszczlaw (962-992); up to the period of this sovereign we have only fables. He became a convert to Christianity, and Poland took rank as one of the political powers of Europe. Mieszczlaw acknowledged himself to be the feudatory of Otton of Germany. In his time the first Polish bishopric was founded at Posen. He was succeeded by his son Boleslas I. (992-1025), who extended his kingdom beyond the Oder, the Carpathians, and the Dnieper. He was recognised as king by the German emperors. After a period of anarchy he was succeeded by his son Casimir (1040-58), whose reign, and that of his warlike son Boleslas II. (1058-1101), although brilliant, were of little real profit to the country. The latter monarch having murdered the Bishop of Cracow with his own hand, Poland was laid under the papal interdict, and the people absolved from their allegiance, whereupon the Poles fled to Hungary. For two hundred years from this time Poland was only a duchy. Boleslas III., surnamed the "Wry-mouthed" (1102-38), an energetic monarch, annexed Pomerania.

In the time of Casimir II. (1177-94) we have the senate established, which was formed from the bishops, palatines, and castellans. His death was
the signal for a contest among the various claimants for the throne, which was speedily followed, as usual, by a division of the country, and during this disturbance Pomoronia emancipated itself from Polish rule. In 1226 the Teutonic Knights were summoned by the Duke of Masovia to aid him against the pagan Prussians; but they soon became as formidable enemies to Poland as the Prussians, and conquered a large part of Podolia and Lithuania. The Mongols swept over the country in 1241, committing great devastations, and defeated the Poles in a battle at Liegnitz. Many districts of the country were now colonised by Germans, and numbers of Jews took refuge in Poland. The Germans obtained great privileges from the Polish king, who was one of the few to endure the Teutonic burgenon. The reign of Ladislaus the Short (1305–33) is important, because in his reign the first Polish diet (1331) was summoned at Checiny. In conjunction with Gedymin, Grand-duke of Lithuania, a vigorous war was carried on against the Teutonic Knights. His son, Casimir the Great (1333–70), increased the prosperity of Poland. Commerce was active, and Danzig and Cracow joined the league of the Hansa. In 1347 was enacted the celebrated Statute of Wilscha, the foundation of Polish law; in this reign also Galicia was united to Poland. With Casimir the dynasty of the Piastas became extinct, after a rule of 510 years, according to the old Polish chroniclers. His nephew, Louis, king of Hungary, succeeded him by the will of the deceased monarch and the election of the diet. On his death without male heirs the succession fell to his daughter Jadwiga or Hedwig, who was induced by the diet to marry Jagiello, Grand-duke of Lithuania, who founded the dynasty of the Jagellons (q.v.; 1386–1572), and first united Lithuania and Poland, thus doubling the extent, though not the population, of the kingdom. In 1410 the Teutonic Knights were defeated in the battle of Grunwald. His son, Ladislaus, who was also chosen king of Hungary, fell at the battle of Varna in 1444 fighting against the Turks. Casimir, who succeeded, recovered West Prussia from the Teutonic Knights and compelled them to do homage for East Prussia. In 1454 was held the diet at Nieszawa, at which the celebrated statute was enacted which conferred great privileges upon the Polish nobility. The brief reigns of Casimir's two sons were marked only by the increased power of the diet, which had by this time absorbed all but the accouts of supreme authority, the great lords of Poland from a monarchy into an oligarchy. The king thus possessed but little power beyond what his personal influence gave him.

Sigismund 1. (1506–48), also son of Casimir IV., had a long and prosperous reign, Poland being at that time the dominant country of eastern Europe. Very different opinions have been held about this monarch, some Polish historians praising his government, while Bohrnskynski and others consider him to have been a weak man. His court was filled with factions fomented by his wife, Bona Sforza, daughter of the Duke of Milan, a malignant and avaricious woman. The doctrines of the Reformation penetrated to Poland, and were a source of fresh discontent. In a war with Basil, the Grand-duke of Russia, Sigismund lost Smolensk, but he was partly compensated by obtaining lordship over Moldavia. In 1529 Sigismund issued a legal code for Lithuania, which forms an important monument of Polish law. In 1537 occurred the first rokok, or rebellion of the nobility against the kingly authority. Sigismund was about to set out to Wallachia, and was obliged to make several concessions before they would accompany him. In 1548 the king died at the advanced age of eighty-two.

He was succeeded by his son, Sigismund II. (1548–72), otherwise called Sigismund Augustus, but this prince was not elected till a debate had taken place about his marriage. He had secretly espoused as a widower a widower of the Granhuse Radzizzill, and the nobles required the union to be annulled, because they fancied that the country

![Poland and Lithuania map](image-url)
would gain more by a foreign alliance. Sigismund, however, carried his point, and his wife was crowned in 1550, but died soon after, not without suspicions of having been poisoned by her mother-in-law, Bona, who in this reign left Poland for her native country, carrying with her a vast amount of treasure. The quarrel between Protestants and Romanists raged fiercely, and the circumstances of the time caused it to spread rapidly in Poland. We hear of persons being burned to death for their adhesion to it. Sigismund showed great indecision in the matter. In 1568, by the diet of Lublin, Lithuania was first declared indissolubly to Poland, and from this time there was to be but one diet for the united realm, and Warsaw, for greater convenience, became the capital. Poland also gained Livonia. In 1572 the king died. In the diet held the year after at Warsaw it was enacted that there should be toleration for all religious opinions, but the nobles were still to have power over their serfs in spiritual matters.

The population almost doubled itself, but the nobles became every year more impatient of restraint, and the crown was now virtually elective. The command of the government was divided into the ordinary diet and the post, or deputies of the nobility, together with the higher nobility, sat in one chamber. The king had the right of summoning the diet, which only lasted for six weeks, and its decisions were required at a later stage, as we see in the splendid triumph of the idea of Saxon supremacy. The unanimity in voting is thoroughly Slavonic, and is to be found in the old Russian folk-notces. The right of forbidding the passing of any measure was called in Poland the liberum veto (in Polish, nie pozwalanie), and sought as legitimate to a stagnant state still. It was employed by many of the corrupt Polish nobles to avoid the detection of their malpractices or to gratify their private malice, and hastened the ruin of the country.

The diet of 1573 elected Henry of Valois (III. of France, q.v.), a workman, who fled in the most ludicrous fashion from the country after a reign of about five months, and was succeeded by Stephen Batory (1575–86), voivode of Transylvania, one of Poland's best kings, who carried on war successfully against the Russians, and compelled them to cross the Dnieper. Batory, the Cossacks of the Ukraine into regiments of frontier soldiers, Batory, who had no heirs, was succeeded by Sigismund III. (1586–1632), the son of Catharine, sister of Sigismund II., who had married John Vasa, king of Sweden. He signed the pacula conventa, as the agreement between the Poles and their king was named, and an alliance offensive and defensive was made between Poland and Sweden. Constant disputes took place between the king and the diet, and he was a great persecutor of the Dissidents, as the Protestants were called. Sigismund assisted the claims of the false Demetrius, who was assassinated at Moscow in 1606, and we find the Poles afterwards taking that city and causing Ladislaus, the son of Sigismund, to be crowned czar; but he was soon defeated, and ultimately fled to Turkey, where the Romanovs ascended the throne in the person of Michael. Nor was Sigismund successful in his attempts to get the crown of Sweden. He died in 1632, and was followed by his sons Ladislaus IV. (1632–48), the electors of Saxony being naturally the closest to the crown, and his brother John, who was elected king; but his election was opposed by Austria and Russia, and in his place was chosen Augustus III. (son of the last sovereign), a weak and incapable man. The condition of the country now continued to decay. During the reign of this dynasty Wallachia and Moldavia were taken by the Turks from the Polish protectorate, Livonia was conquered (1655–21) by Sweden, and Brandenburg established itself in complete independence (1657). In 1652 Sicienski, the convert of the Jesuits, was accepted by the liberum veto. The Cossacks had been gored into rebellion by oppression and religious persecution, as they were members of the Greek church, and finally went over to Russia. This occurred in the unfortunate days of John Casimir; and during the same reign Poland was attacked simultaneously by Russia, Sweden, Brandenburg, and the Cossacks; the country was entirely overrun, Warsaw, Wilno, and Lenberg taken, and the capital taken. Many of the Polish nobles behaved with great treachery, but the invaders were finally driven out. In 1660 Livonia was ceded to Sweden. In 1667, by the treaty of Andruszow, the territory beyond the Vistula was ceded to Russia. John Casimir abdicating in 1668, and retired to France, where he died in 1672.

Michael Wisniewiecki (1668–74), son of a famous general, but a weak and very insignificant man, was elected king—it is said almost against his own will. He was a mere puppet in the hands of his subjects. A war with Turkey was concluded by the ignominious peace of Buczac in 1672, by which the town of Kamienieck remained in the hands of the Ottomans. But the senate rejected the treaty; the Polish army was reinforced, and the Turks expelled; and Maria, the widow of Sigismund, who ruled the Turks at Chezmin the following year. Michael died suddenly in 1674. After some dissensions concerning the election of a successor, John Sobieski (q.v., 1674–96) was chosen, but his reign, although adorned by the splendid triumph of Vienna (1683), was productive of little good to his country, chiefly through the continual dissensions of the nobles. Sobieski's successor the Prince of Conti was legally elected and proclaimed king; but Augustus II. of Saxony, who reigned for seven years, was driven out by the House of Austria, entered Poland at the head of the Saxons, and succeeded in obtaining the throne. Augustus showed little sympathy with his Polish subjects; he promised to reconquer for Poland her lost provinces, but this promise was chiefly made as an excuse for keeping his Saxan army in the country, in violation of the pacula conventa. His war with the Turks restored to Poland part of the Ukraine and the fortress of Kamienieck; but that with Charles XII. brought nothing but misfortune. Cracow was taken in 1702; Augustus was deposed, and Stanislaus Leszyenski (1685–90), was practically in power, while his brother Stanislaus, who had been elected in his place, "all the courts of Europe acknowledged Stanislaus, except that of Peter the Great; and, when the latter defeated Charles at the battle of Pultowa in 1709, Leszyenski was compelled to leave the country. He returned. In this reign Poland lost Courland, one of its siefs, which was given by the Empress Anna to Biron, her favourite. Religious fanaticism was also rampant. The Dissidents were very much persecuted, and a riot having taken place in 1724 at Thorn, several of the leading citizens, including the burgomaster, were put to death. In 1733 a law was passed excluding them from all public offices. This same year the contemplative Augustus died. At the instigation of some of his supporters, Stanislaus Leszyenski, who was then residing in France, succeeded, and by some means returned to Poland and was elected king; but his election was opposed by Austria and Russia, and in his place was chosen Augustus III. (son of the last sovereign), a weak and incapable man. The condition of the country continued to decay. During this reign Turkestan was ceded to Russia, and the more enlightened Poles, seeing the radical defects of the constitution, the want of a strong government, and the dangers of the liberum veto, entered into a league for the establishment of a well-organised hereditary monarchy. The convent parlementary party was now generally hostile to the Turkish influence, while the reformers supported the Jesuits in their exclusion of dissenters.
from public offices. In 1764 Stanislaus Augustus Poniatowski was elected king, chiefly through the intrigues of the Empress Catharine. Although a man of refined manners, he was weak, and not fitted to serve the country at such a crisis. The reforming, or Czartoryski party (so called because it was headed by a member of this celebrated family), had succeeded in abolishing the liberum veto, and effecting many other improvements; but they at the same time more severely oppressed the Dissidents, whom the Russians pretended to protect.

The Confederation of Bar (so called from Bar in Podolia) was now (1768) formed by a few patriots, an army of about 8000 men was assembled, and war declared against Russia. But they were not successful, and a bold attempt to carry off the king also failed. Frederick the Great of Prussia, who had formerly gained the consent of Austria to a partition of Poland, made the same proposal to Russia in 1770, and in 1772 the first partition was effected. The territories seized by the three powers were as follows:

<table>
<thead>
<tr>
<th>Country</th>
<th>English sq. miles</th>

<td>2,700,000</td>
</tr>
</tbody>
</table>

The whole country was now aroused to a sense of its danger; and the diet of the diminished kingdom laboured to amend the constitution. In 1788 a remarkable diet was opened which lasted four years. Many changes were introduced. The liberum veto was formally suppressed, and the throne was declared hereditary. The burgurers were sent to depute to the diet on the same terms as the nobles; the peasants were not set free, but their condition was improved; and the Dissidents were granted complete toleration, although the Roman Catholic was declared to be the dominant religion. In this they were encouraged by Prussia, whose king, Frederick William, swore to defend them against Russia. The new constitution was promulgated May 2, 1791. But some of the nobles were discontented at the loss of their privileges by the new order of things, and formed in 1792 the Confederation of Targovia (q.v.), and at their instigation Russian troops invaded Poland and Lithuania. Prussia now joined the Russians, and a second fruitless resistance to the united troops of Prussia and Russia, which was headed by Joseph Poniatowski (q.v.) and Kosciusko (q.v.), was followed by a second partition (1793) between those two countries as follows:

Cracow, with a small surrounding territory, was declared independent under the protection of Austria. Alexander I. gave the Poles a constitution, including the independence of the ministry, a separate army, and liberty of the press. General Zajacek was appointed viceroy, and the Grand-duke Constantine took command of the army. For some time matters seemed to go on smoothly, but a spirit of discontent soon developed itself. Complaints were made that the freedom of the press was interfered with, and secret societies were formed. An insurrection broke out in November 1830; the grand-duke was obliged to quit the city, and General Chlopicki was appointed dictator. Early in 1831 a large Russian army, under Diebitsch, entered the country. Chlopicki

King Stanislaus resigned his crown, and died at St Petersburg in 1798. He lies buried in the Roman Catholic church there.

The main causes of the fall of Poland appear to have been (1) the want of patriotism and cohesion among the nobles, each pursuing his own interests, and the country thus being divided among a number of petty tyrants; (2) the want of a national middle class, the trade of the country being almost entirely in the hands of Jews and Germans; (3) the intolerance of the Jesuits, who persecuted on the one hand the Dissidents, which caused them to sympathise with Prussia, and on the other persecuted the Orthodox inhabitants of the eastern provinces and the Coassarks, who thus looked to Russia; (4) in a less degree than the first three causes, the weakness of character of the kings—though the throne was not entirely in their hands—confessed that they had no fair play; (5) the want of natural frontiers.

The subsequent success of the French against the Russians and the promises of Napoleon to reconstitute Poland roused him round him the Poles, who distinguished themselves in several campaigns against their old enemies; but all that Napoleon accomplished in fulfilment of his promise was the establishment, by the treaty of Tilsit (1807), of the duchy of Warsaw, chiefly out of the Prussian share of Poland, with a liberal constitution and the Elector of Saxony as its head. In 1806 Western Galicia was taken from Austria and added to the duchy, but the advance of the allied army in 1813 put an end to its existence. After the cessions by Austria in 1809 the duchy contained 58,200 English sq. m., with a population of about 4,000,000. Danzig was also declared a republic, but given back to Prussia (February 3, 1814).

The division of Poland was rearranged by the Congress of Vienna in 1815; the original shares of Prussia and Austria were diminished, and that part of the duchy of Warsaw which was not restored to Prussia and Austria was united as the kingdom of Poland to the Russian empire, but merely by the bond of a personal union (the same monarch being the sovereign of each), and the two states being wholly independent of each other. The remaining parts of Poland were incorporated with the kingdoms which had seized them. The partition of Poland as thus finally arranged was as follows:

| Mohileff, Valholya, Klef, Podilia, and the Kingdom of Poland (see below). Of these portions of the original kingdom of Poland now belonging to Russia it must be remarked that Courland was ceded to Russia in the reign of Catherine II. by the free action of the inhabitants; Klef had belonged to Russia by conquest since 1667.

Kosciusko was appointed viceroy, and the Grand-duke Constantine took command of the army. For some time matters seemed to go on smoothly, but a spirit of discontent soon developed itself. Complaints were made that the freedom of the press was interfered with, and secret societies were formed. An insurrection broke out in November 1830; the grand-duke was obliged to quit the city, and General Chlopicki was appointed dictator. Early in 1831 a large Russian army, under Diebitsch, entered the country. Chlopicki
resigned his dictatorship, and Prince Czartoryski was appointed president of the provisional government. From January 1831 till 8th September of the same year a series of sangri»ry engagements took place, in which the Poles were at first successful. On the 8th of September, however, Paskevitch (q.v.), who had succeeded Lubitsch, took Warsaw, and the insurrection was at an end. The Poles had not succeeded in obtaining any assistance from foreign powers. From this time the independence of Poland was suppressed, and in 1832 it was declared an integral part of the Russian empire. A separate administration was headed by a vicerey chosen by the czar; the constitution was annulled, and a strict censorship of the press was established. Many of the literary treasures were carried off to the public library of St Petersburg. Slight outbreaks occurred in 1846, which were severely repressed. Simultaneous disturbances in the Russian and Austrian portions of Poland met with the same fate. Their leaders in Prussia were imprisoned, but released by the revolution of 1848 at Berlin. In no part of the lost province has the work of denationalisation been more thorough than at Warsaw, where it proceeded quietly, but thoroughly. In Galicia the peasants at the same time massacred many of the nobles. On the 6th of November 1848 the republic of Cracow was incorporated with Austria.

After the accession of Alexander II. in 1855 the country was again thoroughly reorganised. An amnesty brought back many of those who had been expatriated, and various other reforms were hoped for. On the 29th November, on the thirtieth anniversary of the insurrection, many political manifestations took place, but in a formless way elsewhere. On the 6th a rebellion took place, and some persons were unfortunately killed. Warsaw was now declared in a state of siege. In June 1862 an attempt was made to assassinate General Luders, the governor, who was succeeded by the Grand-duke Constantine, the brother of the emperor, the Marquis Wielopolski being appointed chief minister. Meanwhile Alexander II. had made great concessions; the public offices of the country were to be filled by Poles; the Polish language was to be the official one, and municipal institutions were granted to Warsaw and the chief cities. The people, however, received these overtures sullenly, and on the night of January 15, 1863, a secret conscription was held, and those suspected of disaffection to the government were seized in their beds to be enlisted. Attempts were made to assassinate the grand-duke and other Russian officials, and Lithuania and Volhynia were also declared in a state of siege. The committee of the National government issued its first proclamation in February 1863; and a week afterwards Mieroslawski raised the standard of insurrection in the north-east, on the frontier of Posen. The committee (Rzecz') had secret sessions, and was for a long time able to defy the Russian government: its emissaries, called stilettoksi, put to death many obnoxious persons and Russian spies. It also issued two Conclusions from time to time, and many districts of Augustovo, Radom, Lublin, Volhynia, and Lithuania were speedily in insurrection. It was a mere guerrilla war, and no great or decisive conflicts took place; but the sympathy of Europe was largely enlisted on behalf of the Poles. Incendium and murder were rampant; and at last, with the assistance of Prussia and the secret support of Austria, the czar's troops succeeded in taunting out (1864) the last embers of insurrection. Langiewicz, one of the leaders who had escaped, was captured, and murdered in 1878, but at length made his escape into Galicia. From the time of the suppression of the insurrection the kingdom of Poland has disappeared from all official documents. All education in the university and the schools is now carried on in the Russian language.

Among histories may be recommended Histoire de Pologne, by Lelewel (Paris, 1844); Geschichte Polens, by Köppel and Caro (vols. i.-vi., Gotha, 1840—88); Dieje Polakie w Zeitschriften, by Bobrzyński. See also Count Motie's Poland (Eng. trans., 1858), and the present writer's PoZand (1893). For maps of Poland at various dates, see, besides that given above, the statistical maps on p. 646.

RUSSIAN POLAND.—The so-called 'Kingdom of Poland,' united to Russia in 1815, had its own constitution till 1830, and a separate government till 1844, when, after the suppression of the revolt, the last visible remnant of independence was taken away. The administration was at first given to eight military governors, and then to a commission sitting in St Petersburg. Finally, in 1868, the Polish province was absolutely incorporated with Russia, and the ten governments into which it was divided are grouped with the governments of Russia proper. In 1867 the area of the 'kingdom' was about 4,500,000 sq. m., with a population of 5,700,000, of whom 4,300,000 were Roman Catholics, 780,000 Jews, 260,000 Greek Catholics (mostly United), and the rest Lutherans or other Protestants. In 1890 the ten Polish provinces—Kalisz, Kielce, Loniza, Lublin, Piotrkow, Plock, Radom, Siedlice, Sarnecz, and Warsaw—had a population of about 8,105,000. The several areas and populations of these governments will be found in the table at Russia. About 10,000,000 still here and in Prussia and Austria speak the Polish tongue. The surface and roll of the Russian Polish province resembles that of the rest of old Poland; the commerce is still mostly in the hands of the Jews.

POLISH LANGUAGE AND LITERATURE.—The Polish language is one of the most widely-spread branches of the Slavonic family; it forms the western branch together with Bohemian and Sorbian or Lusatian Wendish. Like all the Slavonic languages, it is highly inflected, having seven cases, and, by means of the so-called 'aspect,' expressing very delicate distinctions of meaning in the verb. Like Russian, however, it lacks the imperfect and aorist which are found in Bulgarian and Serbian. It has a rich vocabulary and a great power of compound words. It resembles the Old Slavonic in having two nasals, like the French en and in; these are found nowhere else among Slavs except in a Bulgaro- German dialect. After the introduction of Christianity Latins exercised a great influence on its vocabulary and literature, and subsequent to the 14th century it adopted into its vocabulary numerous German words. Already in the 16th century Polish was a highly cultivated language, and began to supplant Latin, until then the language of the state and of the learned. The best Polish grammars are those of Malecki, Gramatyka Historyczno- Porownawcza Jezu Polskiego ('Historico-comparative Grammar of the Polish Language,' Lemberg, 1879), and G. W. Wassy's Vergleichende Sprachlehre der polnischen Sprache (Berlin, 1845); the most comprehensive dictionary is that of Linde (new ed. Lemberg, 1854—60); that of Banitke (2 vols., Breslau, 1896) is good, and so also is the English-Polish dictionary published at Berlin in 1848.

The history of Polish literature is divisible into five distinct periods. (1) From the earliest times to the middle of the 16th century, the epoch of the Reformation. The Poles, unlike most of their Slavonic kindred, are poor in legendary and cepitricel and number of the early literature is in Latin. Casimir III. (q.v.), surnamed 'the Great,' did more than any other early Polish
monarch for the encouragement of literature, and among other things founded the university of Cracow, which has continued to be the centre of intellectual activity in Poland. The oldest literary monuments is a hymn to the Virgin Mary, ascribed to St Adalbert. The MS, in which it is preserved is dated 1408. Belonging to the middle of the 14th century is the so-called psalter of Queen Margaret, discovered at the turn of the 19th century, which has been edited by Professor Nehring; there is also the Bible of Queen Sophia, which has come down in an imperfect copy, and is said to have been written about 1455; it has been edited by Professor Malecki. Writers of Latin chronicles were Martin Ciurl (died 1560 and 1582); Kadulek (1160-1225), and Jan Dlugosz or Longiussi (1415-80), all of whom were ecclesiastics. The last is also worthy of remembrance as an able diplomatist. Jan Laski, Archbishop of Gnesen (1457-1531), published a valuable collection of the oldest Polish laws, Communie Instructi Polonicie Regni Privilegij. In 1474 the first printing-press was established at Cracow by Günther Zainer; the first book in the Polish language was published there in 1521. In 1543 died the great astronomer Nicholas Copernicus. Some other specimens of other works of the 16th century will be found collected in the valuable work of Nehring, Altpolnische Sprachdenkmaler (Berlin, 1887).

(2) The second period of Polish literature embraces that which is called the golden age (1548-1606). The series of poets begins with Nicholas Roy (1583-69); commonly called the 'father of Polish poetry,' who spent his life at the courts of the Sigismunds. He was a Protestant. His best work is Zwiewnice i albo zygot Poczeciego Chlojowiecka ('The Mirror: or the Life of an Honourable Man,' 1567); he also wrote a play on the subject of Joseph. Although his language is rough and careless, there is much shrewdness and satire in his writings. Jan Kochanowski (1530-84), called the prince of Polish poets, has left a great deal of verse, the most beautiful of which are his Treny or Lamentations on the death of his father. His Uganda, a historical translation of the Jerusalem Delivered of Tasso, Szarycz (1581) introduced the sonnet into Polish. Szymonowicz (1557-1629) was a writer of good pastoral poetry ('Sielanki'), as was also Zimowycz (1629), a native of Lemberg. Sebastia Knioowicz, called Acorna (died 1602), is celebrated as a satirist and descriptiver poet. The Reformation made rapid progress in Poland; many of the nobility were Calvinists, and the Socini became to reside in the country. Translations of the Bible appeared, but the Jesuit reaction soon made itself felt, especially under the influence of Skarga (1552-1612), renowned for his pulpit eloquence. Among the historians of this period the most celebrated are Martin Bielski, whose Chronicle was continued by his son Joachim; Latka Gornicki (died 1591), author of a history of the Polish crown (Dziwce w Koronie Polskiej), was a Jesuit; Cracow (1557) and 1582), whose Chronicle of Lithuania (Königsh. 1582) is an admirable work; and Papatzek (died 1614).

(3) The third period of Polish literature, also called the Macaronic (1606-1764), is coincident with the classic period in Latin literature and obtained for the language a footing in Poland about 1566, through the influence of Cardinal Hüss, soon got possession of the schools, and seriously checked the intellectual development of the nation. The literature of the period is for the most part poor, consisting mainly of bombastic panegyric; the language being corrupted by Latinisms and frequently by the introduction of whole Latin sen-

...tenences—hence the term Macaronic. To this period belong Casimir Sarsibeski, known by his Latin name Sarbitius (1560-1610), a celebrated writer and poet. He was a bishop and a poet of learning who has been called the author of the poem Wysna Chrystianata, or War of Chocim, long preserved in manuscript; Kochowski (died 1699), a soldier-poet, who has left some sprightly odes; Twardowski (died 1660), a very prolific writer, author of a poem on Ludzislan (Lithuania); (1610-1650), who has left some bitter satires reviving his name as a genius, and who was betrayed to the Swedes; Choseiski, the translator of Lucan; Morsztyn, the translator of Corneille; and Elizabeth Druszaacka (died 1760), whose writings show some feeling for nature. History again begins in fashion, in spite of having been written in the golden age in Polish; we may mention Starowowski; (died 1656), author of Poloniae sive Status Regni Polonicie Descriptio (Wollenbutfett, 1656), and other works; Kojałowicz, a Jesuit (died 1617), who wrote a History of Lithuania; and Kaspar Niesiecki, a Jesuit (died 1744), whose Krono Polonae (4 vols. Lemb. 1728-43) is the most important work on Polish heraldry.

(4) The fourth period is that of the reign of Stanislaus Poniatowski and the dismemberment of Poland, till the rise of romanticism (1764-1822). This period marks the transition partly to the influence of French culture, partly to the development of literature and science by King Stanislaus, the princes Czartoryski, Jabłonowski, and other noblemen, and the educational reforms of Stanislaus Konarski (1700-73). The good work begun by Konarski was carried on by Kopeyzyński (1735-1817) Ignacy, who was the first to establish on a scientific basis the grammar of the Polish language in his Grammarka Narodowa; other authors were Bohomolcz and Zablocki, who adapted a great many French pieces for the stage. But the best writer for the stage was a man who belonged to a later period. The most noted dramatist, however, of this time, who may perhaps be called the real founder of the Polish stage, was Boguński (1739-1829), who wrote above eighty plays, the majority of which, under the title of 'Dziela Miejski,' were published at Warsaw (9 vols. 1820). The most conspicuous poet of this time was Ignacy Krasicki (1735-1801), who tried all kinds of literature—an epic on the war of Chocim, a weak production, and some satires and fables. We must also mention Trembecki; Wojciech Jagloń, the grocer; Grosz, and Weyzy Adal. Naruszewski, who was a macaronic poet, but he wrote a valuable History Narodu Polskiego ('History of the Polish People'), which he carried down to the year 1836. In 1801 the historian Tadeusz Czéki, Franciszek Dunowicz, and Bishop Jan Albertrandy founded at Warsaw the 'Society of the Friends of Knowledge,' which especially under the auspices of Stanisłav bore good fruit till it was dissolved in 1832, when its library of 50,000 volumes was carried off to St Petersburg. At the same time Józef Ossoliński, Hugo Kołataj, and Konstanty Potocki, a Polish poet and writer, exercised a great influence on the renunciation of the national spirit. Karpinski (1745-1825) was a very popular poet as a writer of sentimental elegies and idylls, and Woroniez (1757-1829) was celebrated both as a poet and divine. Niemecwiecz (1757-1841) was a statesman and wrote the first of his historical songs (Spiewy Historyczne). Lastly, as the great precursor of the romantic school, must be mentioned Kazimierz Brodziński (1791-1835), whose idyll Wiesław has been much admired.

(5) The fifth period comprises from 1822 to the present time; the era of romanticism, dating from the appearance of Mickiewicz, the greatest Polish poet. At Wilno, which after 1815 became the centre
of Polish literary activity, several young men united, with Adam Mickiewicz (1798-1855) at their head, in a crusade against the still dominant French school of literature. After a short stay in Russia, Mickiewicz emigrated, in 1809, and spent the last part of his life at Paris. He died at Constantinople, whether he had gone on a political mission at the time of the Crimean war. We have only space to mention some of his chief works, his Ballads, Sonnets, Konrad Wallenrod, and Pan Tadeusz; the last of which were translated into English, and are now included in the English language. Anton Malczewski (1792-1826), remembered by his Maria, a pathetic story of the Ukraine, was a prominent poet of what has been called the Ukraine school; Goszcynski (1806-76) was author of the narrative poem Zamek Kaniowski; Bohdan Zaleski, author of Dukh od Stepni; others are Odyncie, the friend of Mickiewicz, Siemiencki, Garzyński, Gaszynski. The two names most worthy to be placed by the side of that of Mickiewicz are those of Sigismund Krasiński (1812-59), author of the strange poem Nadwórna Komedia (the Undivine Comedy), and Julius Słowacki (1809-49). Most of these men belonged to what was called the Polish Emigration, whose headquarters were at Paris. Of the Polish novelists we have only space to mention the prolific Józef Ignacy Kraszewski, whose works amount to 312, and Henrik Sienkiewicz. The most original writer for the stage whom the Poles have produced is Count Alexander Fredro (1783-1876); he is a thoroughly national writer; although French influence is visible in his pieces, the characters are Polish. Many distinguished historical writers belong to this later period, of whom we may mention Janchim Lelewel (1786-1862), the author of many works of the greatest value, Sniżski, Schmitt, Sznajchla, and Michal Bohurzynski, professor in the university of Cracow. By these means the history of Poland has been treated in all its details with great vigour. Among later poets may be mentioned Pol, Ujejski, and Lenartowicz; Adam Asnyk, the most popular of recent Polish poets; and the poetesses Gabriela Zmichowska (1856-78) and Marya Krzynówek. The history of Polish literature has been written by Bentkowski and Wisniewski. Mention may also be made of Nischmann's Geschichte der Polnischen Literatur (1881), and the present writer's Early Slavonic Literature (1886) and Poland (1893).

Polar Bear. See Bear.

Polar Circle. See Arctic.

Polar Exploration. In scientific geography much of the best work done in the 19th century is due to discoveries made in the Arctic and Antarctic regions. In the former, more especially, not only have new lands been surveyed, but large and important accessions have been made to several branches of natural science. The original motive, however, in England at least, for exploring the Arctic regions was to discover a route to the wealthy countries of eastern Asia, and to share in the traffic monopolised by Spain and Portugal when at the height of their power. Thus arose a double series of attempts, either to coast westward along the north of Europe and Asia, or to sail westward across the Atlantic; the latter being afterwards modified into attempts to coast westward along the north of America. Hence arose the terms ‘North-east Passage’ and ‘North-west Passage.’

Some have traced the history of Arctic exploration to the time of Knipovich, who, in his translation of Orosius (q.v.), inserted an account of the voyages of Oethere and Wulfstan, narrated to him by Oethere himself, who seems to have sailed round the North Cape to Lapland. The voyages of the Norsemen to Greenland (q.v.) and the opposite coast of America in the 10th and following centuries may be regarded as to some extent coming within early Arctic attempts. Cabot’s discovery in 1497 of Newfoundland and Labrador might, however, be termed the first attempt to explore the opposite Arctic regions—for the earlier expeditions claimed on behalf of Portugal must be regarded as mythical. Three years after Cabot, Gaspar Cortereal and his brother made two separate voyages in the same direction, sailing northwards by Labrador, where they were wrecked on 30th May 1498. Bunge, a Danishman, commanded in 1553 by Sir Hugh Willoughby led the way to the North-east Passage. Willoughby sighted Nova Zembla, but he and his men ultimately perished on the coast of Lapland. Chancellor, who accompanied him, landed in Russia near Archangel. Other Englishmen followed, Burroughs (1556), Pet and Jackman (1580), Henry Hudson (1608-9), Wood (1676), but none succeeded in getting much beyond Nova Zembla, though they did good work in exploring the north coast of Europe, Spitzbergen, and the other islands in these seas. In 1594-97 Barents, a Dutchman, led three expeditions, wintering on the north-east coast of Nova Zembla, 1596-97 (see HARENTZ). After the failures of Hudson and Wood in the 17th century, the attempt to sail eastwards came to be considered quite hopeless. In 1683 and 1684, Whidbey, sailing along 81° 30' N., in the neighbourhood of Spitzbergen.

Meanwhile some exploration of the Arctic parts of America had been going on. Frobisher first sailed in 1576, and in 1583-88 the great navigator Davis sailed up the strait bearing his name to 72° 41' N., and coasted the west of Greenland, ‘the land of desolation.’ In a tract of Davis’ published in 1596, there are arguments for a North-west Passage. Hudson, who had tried the North-east Passage, discovered in 1610 the strait and great bay which bear his name. From the size of the latter it was concluded it may be part of the Pacific; but that was disproved by Button, the next English explorer (1612). In 1615-16 Baffin, who went out at first under Bylot, had had some scientific training, proved himself as skillful a navigator as Davis. He found the great northern outlet to Baffin bay, and recorded some important magnetic observations. After the expedition of Fox and James in 1631, which only led to the partial exploration of what then was named Fox Channel, the North American coast was neglected for more than a century.

Russia was naturally interested in the exploration of the Siberian coast, and from Peter the Great’s time took her proper share in the maritime discovery. Behring, after receiving instructions from Czar Peter on his death-bed, sailed from Okhotsk, and discovered the straits which bear his name. In a second voyage (1741) he sailed from Petropolokvivo and explored part of north-west America. Another Russian expedition in 1742 found (but did not succeed in rounding) the most northerly point of Siberia, named from the discoverer Chelyuskin (or Severo); and an earlier one sailed from the Yenisei to 75° 15' N. In 1765 Chitsakoff sailed to Spitzbergen, and finally reached 80° 4' N. The New Siberian Islands were explored by Hedenström in 1809-11, by Anson in 1835, and in 1848-51 by Bering. He explored the Siberian coast between Cape Chugskoi and the Kolyma in 1820-23, and in 1848 Middendorf laid down the unvisited coast in the neighbourhood of Cape Chelyuskin. In the reign of George III, Franklin was a member of an expedition to search for the Northwest Passage, the starting point of this expedition being at the Cape of Good Hope. Captain Phillip (afterwards Lord Mulgrave) sailed in June 1773 to Spitzbergen, where the heavy pack-ice kept him nearly a month from proceeding farther north. Finally he reached 80° 48' N., and Cook, who next made the attempt,
Polar exploration could only penetrate to 70° 45'. The government offered a prize of £5000 to any crew that should reach 89° N. long.; but after those failures there was no effort made till 1806, when Scoresby reached 81° 45' N. immediately above Spitsbergen. In following expeditions Scoresby explored Jan Mayen Island and the east coast of Greenland, largely adding to our knowledge of the physical geography and natural history of the Arctic regions. The expeditions of Buchan and Franklin in 1818, of Clavering in 1823, of Graah in 1828, of De Blosseville in 1832, did not reach higher latitudes than those which preceded them.

To encourage polar exploration on the North American coast the British government had promised a reward of £20,000; yet nothing was done till the Admiralty in 1818 sent out Ross and Parry, who only explored part of Lancaster Sound. Next year Parry alone discovered Prince Regent Inlet, Barrow Strait, and (110° W.) Melville Sound. Following up this line of exploration, Ross in 1829 at last reached a point only 200 miles from Turnagain Point, which had recently been found by another expedition sailing eastward from Behring Strait. Ross then named Boothia Felix, in which the magnetic pole lay, and King William's Island. In 1826–27 Franklin traced the North American coast from the Mackenzie River westwards to Cape Beechey, 860 miles, while his companions, Richardson and Kendall, proceeded eastwards towards the Coppermine River. Deneal and Simpson in 1838 extended the survey of the American coast for about 100 miles, from Point Turnagain. In 1846–47 Dr John Rae explored the west shore of Boothia Gulf, and discovered Boothia Felix to be a peninsula. In 1851 the same explorer surveyed the coast from the Mackenzie River to King William Land, and also the south-east coast of Victoria Land.

The success of Ross led to Sir John Franklin's expedition (left England May 19, 1845), so unfortunate to him and his crew, so famous from the
number of search-parties which it occasioned. His object was to penetrate to Behring Strait from Lancaster Sound (see Franklin, Sir John). In 70° N. lat., 98° 30' W. long., on the west side of King William's Land, the ships were beset, and Franklin died June 1847. The survivors abandoned the ships, and all perished. Many search expeditions were sent out. One of these, under Collinson and M'Clyre, sailed from Plymouth to Behring Strait in 1850. Fixed in the ice on its eastward voyage, M'Clyre's ship was rescued next spring by Sir Edward Belcher, about 60 miles west of Barrow Strait. Belcher now returned towards the Atlantic, and thus M'Clyre with his crew reached England in 1854 after actually traversing the North-west Passage from ocean to ocean. He therefore received the honour of knighthood, and a sum of £10,000 was voted by parliament to him and the crew. One of the last search expeditions was that in the Fox, under Captain (now Sir) Leopold M'Climock, sent out by Lady Franklin in 1857. M'Climock obtained many relics from the

Eskimo of Boothia, and in a cairn in Point Victory found the record which told the story of the expedition. Perhaps we should here note the fact that afterwards, 1879–80, one of the United States search expeditions, under Lieutenant Schwatka, found evidence that Franklin had really completed the discovery of the North-west Passage. Owing to the different Franklin expeditions from Great Britain and the United States the whole Arctic coast of North America was explored almost exhaustively, so that several routes are now completely mapped between Davis Strait and Behring Strait. For commercial purposes, however, the North-west Passage is of no value whatever.

And now to return to the North-east Passage. In 1827 Parry sailed to Spitzbergen, and after much toilsome effort reached 82° 40' N. After that little was done in this region till Sweden began to take an active interest in the exploration, under the active guidance of Professor (afterwards Baron)
Nordenskiöld, who in 1838-72 did much exploring work in the Spitzbergen islands and seas. In two voyages he reached the Gipsy Compass on the island of Spitzbergen, in 1838, and Cape Chelyuskin, 77° 41' N., and after wintering near Behring Strait sailed into the Pacific and reached Yokohama, 21 September 1839. Thus, three and a quarter centuries after the attempt of Willoughby, the North-East passage was at last completed. Before that date an Austrian expedition under Lieutenant Payer and Wegrepp had been singularly successful, having discovered an island about 200 miles north of Nova Zembla, as large apparently as Spitzbergen. This new country, Franz-Josef Land, extends from 80° N. to about 83°. It was still farther explored to the north-west in 1880 by Mr. Leith Smith, who spent the winter 1881-82 there, and his companions escaping with great difficulty. The Jackson-Harmsworth expedition did valuable work there in 1894-95.

The more recent exploration to the north of America has added little to our geographical knowledge, however interesting in certain scientific aspects. The expedition of Kane and Hayes in 1833-55 reached in sledges Cape Constitution in 82° 27' N., and saw what appeared to be an open polar sea. Hayes again (1860-61) reached 81° 37' N. In 1877 the Polaris, under Captain C. F. Hall, 11° 30' from the U.S., and which reached the latitude 82° 16', which was surpassed in 1876 by the English expedition under Captain Nares; Captain A. H. Markham, by means of sledges, reaching 83° 20' N. At the same time Adrich explored the north shore of Grinnell Land. More famous and more disastrous was the 'Lady Franklin Bay Expedition,' 1881-84, conducted by Lieutenant Greely; the relief party sent in the summer of 1883, being unfortunately entrusted to military men, failed to reach the explorers, who, therefore, compelled to abandon their ships and find their way southwards through almost impassable ice. In October 1883 Greely and his brave companions landed at Cape Sabine, the bleakest spot probably in all the Arctic regions; and there in June 1884 Commander Selby found the six men who still survived. Greely and his associates are the subject of scientific interest the 'Lady Franklin Bay Expedition,' 1881-84, conducted by Lieutenant Greely; the relief party sent in the summer of 1883, being unfortunately entrusted to military men, failed to reach the explorers, who, therefore, compelled to abandon their ships and find their way southwards through almost impassable ice. In October 1883 Greely and his brave companions landed at Cape Sabine, the bleakest spot probably in all the Arctic regions; and there in June 1884 Commander Selby found the six men who still survived. Greely and his associates are the subject of scientific interest.

The Jeannette expedition under Commander De Long, sent out by the New York Herald in 1879 to the north by Behring Strait, ended in disaster. The vessel was crushed in the ice in June 1882 in 77° N., 153° E., and De Long and many of his men perished. The ice plateau which covers Greenland (q.v.) was in 1898 crossed from east to west by Nansen and Peary did good work there in 1898-99. In 1899-90 Nansen (q.v.) undertook a more adventurous journey, drifting in the frozen-in Fram as far north as 84° 4', and with one companion penetrating on foot to 88° 14'; all returned in safety. Andre started on his still more adventurous balloon journey to the Pacific and in 1896-97 the Duke of Abruzzi reached lat. 86° 19' 48".

At the suggestion of Lieutenant Weydrecht, an International series of polar observatories was established around the north pole area, for the purpose of continuous observation beginning with August 1882. The stations selected were the following: Rossiseknp, in Lapland (Norwegians); Ice Fjord, Spitzbergen (Swedes); Lena Mouth, Siberia, and Möller Bay, Nova Zembla (Russians); Dickson Harbour, mouth of the Yenisei (Danes); Drygalski (Dutch); Great Slave Lake (English); Point Barrow on north coast of America, east of Behring Strait, and Lady Franklin Bay, in Grinnell Land (the United States, the latter being Greely's expedition); Cumberland Bay, Davis Strait (Germans); Jan Mayen Island (Australians); Goldhaber, Greenland (Danes). The Germans had also a station on South Georgia Island, on the verge of the Antarctic, and the French on the south coast of Patagonia. The result was a series of observations of high value on the physics, meteorology, and natural history of the polar, especially the magnetic situation.

Thus, the expeditions are all still in progress, and the result of the last one which was continued for some years under Bunge and Toll, who not only explored the mainland, but made a thorough investigation of the New Siberian Islands.

It only now remains to survey shortly the polar explorations of the mighty Southern or Antarctic Ocean. Some of the earlier navigators of the 16th and 17th century were drifted south as far as South Georgia and South Shetland. Cook was the first to undertake a systematic exploration of the region, sailing all round at a high latitude, and so disproving the theory that there existed an entrance to the Antarctic to be found on old maps. Cook reached 71° 15' S., in 106° 50' W. In 1821 the Russian Bellinghausen discovered the islands named Alexander Land and Peter Land. Weddell afterwards sailed south to 74° 15', and in 1851 Biscoe discovered Enterprise Land, 65° 57' S., and Graham Land, 67° S. The French expedition, 1838, under D'Urville, found its advance to the pole blocked by a bank extending east and west for 300 miles; La Terre Adélie, in 140° E., was first named in this voyage. In 1840 the United States expedition under Captain Wilkes discovered a long coast-line, apparently extending from Enterprise Land eastwards to Ringgold's Knoll, but the only part of this which has since been found was discovered by Balleny in 1839. The most important results obtained in the Antarctic region are due to Sir James Clark Ross, who made three voyages, 1839-43, discovering Victoria Island, with a lofty range containing the volcanoes Erebus and Terror. He traced the coast from 71° S. to 78° 10', the highest latitude yet reached in the Antarctic, after passing some ice-floes which were 100 miles broad. These southern expeditions of a like nature which the Southern Continent, in which some of the greatest explorers, have supplied valuable information for students of magnetism, meteorology, geology, and natural history, besides extending the bounds of geographical science. The Challenger expedition only just crossed the Antarctic circle. The general result of all the exploring work is that in the north polar regions the unknown has been pushed back to within 80° N. lat.; while in the south, the Greenland and the Nova Zembla regions exploration has been carried to within about 400 miles from the North Pole. Once again, therefore, with the exception of patches here and there, the southern pole region is a great blank within the Antarctic Circle. The Australians have been making efforts within the past few years to take up Antarctic exploration afresh, but nothing has yet been done. The Royal Geographical Society in England has again raised the necessary funds for an Antarctic expedition, and Germany provided for one on an ample scale in 1890 under Von Drygalski.

The physical geography of the north and south polar regions is largely treated at ARCTIC OCEAN, ANTARCTIC OCEAN. See also GEOGRAPHY, POLAR.
Polarisation.

(1) Of Light.—An ordinary narrow beam of sunlight has no sides, and is always divided into two equal beams by a crystal of ice—lact also. A thin plate of doubly-refracting rock crystal, or of some other glass or water, will then be found in general that different results, as regards the intensities of these two beams, are produced by turning the crystal of Iceland spar round the axis of the beam into different successive positions. The beam is no longer the same all round, but has acquired sides. On the vibratory or undulatory theory of Light (q.v.) this shows that the vibrations must be transverse to the direction of propagation (see POLARITY).

Suppose a long cord, fixed to a distant wall, to be held in the hand; apply a sharp up-and-down motion, and the cord will remain always parallel to the cord to the wall; this illustrates the mode of vibration in a beam of plane polarised light. Make the hand move in a circle, in a direction contrary to that of the hands of a clock; a wave will run along the cord in a single plane all the way; and will advance after the fashion, of a coke-screw; this illustrates the mode of vibration in a right-handed circularly polarised beam of light. Make the hand move in a circle clockwise; the wave-screw advances in a left-handed circularly polarised light. Make the hand move in an ellipse; an elliptical disturbance travels, screw-fashion, right- or left-handed as the case may be; this represents elliptically polarised light.

Communicate a series of disturbances of the greatest irregularity, in which no one direction, up or down, right or left, has on the whole any predominance; the irregular succession of transverse disturbances which will travel along the cord will represent the vibration in a beam of common or natural light.

Assume that while communicating these irregular disturbances to the beam the hands are employed in making the cord travel with reference to any particular direction, say up and down; the vibrations in that direction are on the whole less than those from right to left; and the whole complex of irregular disturbances would, if the wave trains all tend to fill up an ellipse with their trace-marking rather than to fill up a circle, as the vibrations in common light would tend to do; this would represent the nature of the vibrations in partially polarised light. Now suppose a slot in a board, which will allow the cord to swing from end to end of the slot, but will not allow the cord to swing athwart the slot; all those oscillations or components of oscillation which are parallel to the slot will be able to traverse the slot; but those which are at right angles to these will not be allowed to pass. On endeavouring to transmit light, and upon the complex of oscillations which illustrate the vibrations of common or natural light, it will be found that no motion at right angles to the slot is transmitted, and that what does pass through is a complex of irregular oscillations transmitted by the first thin plate through the second slot, at right angles to the first, will cut off the whole of what passes through the first; and the propagation of transverse oscillations along a cord may thus be entirely checked. If, however, the second slot be parallel to the first, all the oscillations transmitted by the first may pass through the second also; and if it lie in an intermediate direction, the second slot will allow a proportion to pass, which depends upon the angle between the two slots, being proportional to \( \cos \theta \), where \( \theta \) is that angle. The first slot illustrates the functions of a polariser; the second illustrates those of a second polariser or analyser. A polariser reduces incident common light to a plane polarised condition, and an analyser at right angles to the polariser will quench it almost completely.

The phenomena of polarised light were first observed in sunlight reflected from water or glass. Common or natural light so reflected is always, except when it retraces its path by direct reflection, in fact, plane polarised. The polarisation is more or less complete according to the angle of incidence. At one particular angle of incidence the reflected light is as nearly plane polarised as the particular reflecting substance employed can make it. At this angle, the so-called angle of complete polarisation, the reflected and the refracted rays are (or tend to be) at right angles to one another, and \( \tan \theta = \mu \), where \( \theta \) is the angle between the incident ray and the normal, and \( \mu \) is the index of refraction (see REFRACTION).

Metal reflectors have no angle of complete, but they polarise the light, especially when the angle of incidence is such as to make the reflected light to be plane-polarised. Metal reflectors, which are not polished with a plane, are termed `unidirectional'; and such substances as glass, which are usually said to have an angle of complete polarisation by reflection, it is only those whose index of refraction is \( \approx 1.46 \) which can completely polarise common light. In the case of the reflected light from the glass of the reflected plane polarised beam is in that of the original incident beam of common light as 6:22 to 100, or 6:32 per cent. The intensity of light polarised by one reflection is therefore a good deal less than the 50 per cent, which might be secured by any contrivance which effectually acted in a way analogous to the first slot above mentioned. The intensity of light polarised by reflection is greatly improved by using, instead of a single reflecting plate, a pile of plates. A crystal of tourmaline or of isodi-sulphate of quinine will, on the whole, allow only light polarised in one particular plane to pass through; but then it darkens it and colours it. Advantage is accordingly taken of the property of a doubly-refracting transparent crystal, such as Iceland spar, of dividing an incident beam of common light into two beams which are, in any given part of the crystal, polarised in planes at right angles to one another, and each of which possesses (absorption apart) half the intensity of the original beam. See REFRACTION (Doubly).

As these two beams diverge from one another they form a plane carried in the plane of the paper, and it is easy to arrange that one of them shall remain parallel to the axis of the incident beam and of the apparatus, while the other is allowed to wander away laterally; and this is the basis of the construction of the prisms of Nicol, Pouchault, Wolfsen, Rochon, and others, which receive incident ordinary light and transmit plane polarised light.

Two beams of plane polarised light can interfere with one another (see INTERFERENCE) when their vibrations are wholly or partly in the same direction, but not if they are at right angles to one another; and a beam of light polarised in any way can give rise to the phenomena of Diffraction (q.v.).

On interposing in the path of a plane polarised beam of light an analyser, so placed as to allow none of that light to be transmitted, and then changing the analyser a thin film of a doubly-refracting substance, such as mica, the field of view may become filled with light. The doubly-refracting film generally breaks the incident plane polarised beam into two parallel, but not if they are at right angles to one another, and on the whole coincident if of sufficient breadth. These two beams are differentially retarded in the mica; and, according to the amount
of this relative retardation and to the position of the principal plane of the incorporated film, their resultant, that which reaches the analyser, may be a beam plane polarised in the original plane, plane polarised in another plane, elliptically polarised, or circularly polarised. In all these cases except the first, the analyser lets some light through. If we substitute in the analyser a doubly-refracting crystal, there will in general be two images seen on looking through; but as this crystal itself introduces relative retardations, the result of which depends on the wave-lengths—i.e. on the colours—the different wave-lengths may give different relative retardations, and the two images may appear in the eye as one. In this case the two images may thus be coloured; and when coloured they will be complementarily coloured. The phenomena of colour produced by the reflection of polarised light upon various doubly-refracting crystals and films, &c.,—all which colour-phenomena, are due to varying relative retardations of ordinary and extraordinary rays in doubly-refracting media, and are either uniform all over the resultant wave-front or vary with respect to particular parts of it—are of great value. These give the same beauty. For an account of these we refer to Thomas Preston’s Theory of Light (Lond. 1890).

A beam of plane polarised light may be recognised by means of a crystal of Iceland spar. Paste a piece of paper with a pin-hole in it on one end of the crystal; look through, turning the crystal round, each of the two images waxes and wanes and disappears alternately with the other. In partially polarised ordinary light, and in elliptically polarised light, the two images wax and wane alternately with one another, but do not disappear. In circularly polarised light the images remain equal to one another, and present no variation of intensity. Circularly or elliptically polarised light is converted by a plate of mica of proper thickness into plane polarised light; natural light, unpolarised or partially unpolarised, is not so affected by the same plate of mica. These criteria enable the character of a given beam of light to be readily recognised.

The name of Rotatory Polarisation is given to the phenomenon observed when a beam of plane polarised light is sent through a slice of quartz cut parallel to one axis. The plane of polarisation is found to have been rotated, and that into a different position for each component colour; so that, with white light incident, a crystal of Iceland spar gives two images complementarily coloured, and varying in colour on rotation of the prism. This property of rotation is shared by many substances even in solution: cane-sugar, grape-sugar, camphor not like quartz, rotating the plane of polarisation to the right (dextro-rotatory); fruit-sugar and starch rotate the plane to the left (levo-rotatory). Upon this property are based various instruments for the determination of sugar in the solution called saccharimeters. If the light whose plane has been rotated be reflected back through the plane-rotating medium, the rotation is reversed, and the light emerges polarised in the original plane. A somewhat similar phenomenon, though much less pronounced, is observed on passing a beam of light through heavy glass in a strong magnetic field; but here, if the path of the light be reversed by reflection, the rotation of the plane is not reversed but doubled.

As to the direction of vibration in a plane polarised light, it is to be noted that in the production of a plane polarised light by reflection it is necessary to consider whether the vibration is to be polarised in the plane of incidence—i.e. in a plane containing both incident and reflected rays: the question is whether the vibration is in this plane or at right angles to it. Fresnel worked out the consequences of the vibration being at right angles to this plane, and arrived at (on the assumption that the density of the ether in two medium, at whose bounding surface reflection takes place, is different in the two media, while its elasticity is the same in both) at consequences consistent with experiment. Neumann and MacCullagh, from the contrary hypothesis of the uniform density of the ether, and on the hypothesis that the vibrations are parallel to the plane of polarisation, arrived at optical conclusions which, so far as it is possible to test them by experiment, are equally consistent with observation. Clerk-Maxwell's demonstration of the phenomena of light, confirmed by Hertz’s researches (see Magnetism), requires that there should be an undulatory propagation of electric disturbances at right angles to the plane of polarisation, and of magnetic disturbances parallel to that plane.

Polarisation of light is useful in several ways. A polariser can be made to cut off the glare from the surface of water while we look into its depths; or to cut off a large portion of the light which is reflected from haze and obscures our view of landscape; or it may be used in examining the light of the sky, for it is possible to account for the phenomenon of skylight by the rotation of light in reflection (see Sky). A polariser and analyser are of use in examining the strained condition of glass which, when heated or bent, &c., or too suddenly cooled, will give rise between crossed prisms to phenomena analogous to those produced by a doubly-refracting crystal; and they are also of use in low-power microscopic work for the examination or identification of crystals and of many organic structures. Crossed prisms have also been used to reduce the intensity of a beam of light to any required percentage for photometric purposes.

(2) Polarisation of the dielectric or medium between two opposite charges of electricity; a condition of stress.

(3) Polarisation of a Galvanic Cell.—Production of a reverse ‘electromotive force’ by the deposition of elements of the electrolyte upon, or their combination with, the plates of the cell.

(4) Polarisation of Electrodes.—An entirely similar phenomenon in an electrolytic cell. When the battery is taken off, a reverse current flows from the electrolytic cell; this is the basis of the gas battery and of the modern accumulator (see Electrolysis).

Polarity, in physical science, a word of various application; but in all its uses there is present the idea of a directed quantity or Vector (q.v.). A sphere, situated in space, is a perfect type of all-sidedness, presenting the same aspect in every direction. Let this sphere, however, begin to rotate about some diameter, and at once it becomes a polar body; it becomes possessed of polarity (see Polars). Looked at from one end, it appears rotating clockwise; looked at from the other, it appears rotating counter-clockwise. A similar polarity is acquired by a body of any shape when it is set spinning about some polar axis. Hence we may take rotation as a very perfect illustration of kinematic polarity.

Perhaps the most familiar example in physics of a polar body is the magnet. Its polarity is a force-polarity, the ends or poles of one magnet having a certain magnetic power upon the ends of another. This particular action is, however, only one of a host of manifestations of what is known as Magnetism (q.v.); and the general tendency in modern theory is to explain all magnetic phenomena as being essentially rotations of a physical, dynamical point of view, the conception of rotation as a true type of polarity. The phenomena of statical electricity have also been discussed as analogous to certain phenomena in vortex motion.
In electrolytic polarisation, however, it is difficult to see any rotational analogy. Here the electrodes which bring and carry away again the electric current flowing through the decomposing liquid acquire new properties and functions which have distinct directive relations to the current itself and prevent them. See Electricity, Induction, Magnetism.

In all the cases so far mentioned the polarity or polarisation involved is of such a nature as that originally typified by the sphere's rotation; there are two entities in which some respects have opposite characteristics. In polarisation of Light (q.v.), however, this condition is no longer always fulfilled. For instance, a plane polarised ray of light which is stopped by a Nicol prism passes more or less completely as soon as the prism is rotated around an axis colatitude with the ray. The ray has, in fact, peculiarities as regards its sides—its 'polarity', is strictly speaking, lateral, not polar. On the other hand, in a circularly polarised ray we have, according to the ordinary theory, a true kinematic polarity of a rotational kind, so that, looking along the ray we are able to distinguish right-handed and left-handed circular polarisations. It may be mentioned as a final illustration that the rotation of the plane of polarisation by means of quartz or a saccharine solution is not a real polar phenomenon, the rotation being for any one substance in the plane normal to the travelling ray; but that the rotation of the plane of polarisation in a magnetic field is a true polar phenomenon, changing sign with the direction of the field.

**Polar Lights.** See Aurora Borialis.

**Polder,** in the Netherlands, is land below the level of the sea or nearest river, which, originally a morass or lake, has been drained and brought under cultivation by throwing sand or gravel into the water. A polder, formed of a canal of sufficient height to command a run towards the sea or river, is made, and when carried quite round, as in the case of the Haarlem Lake, it is called the Ringovart. At one or more points on the embankment apparatus for lifting water is placed, and worked by wind or steam power. If the lake deepens towards the centre, several embankments and canals are necessary, the one within the other, formed at different levels as the water-surface becomes lessened, a connection being maintained with the outer canal, which secures a run for the water. In the Netherlands in North Holland are four canal systems, the land between forming long parallelograms. The water from the inner space is lifted into the first canal; that again, with the drainage of the second section, is thrown into the second, and so on until the outer canal is reached and the water obtained. The polders in the Netherlands are very numerous, the most important being the Haarlem Lake (q.v.), possibly to be surpassed by that of the Zuider Zee (q.v.). See also Holland, Vol. V. p. 739.

**Pole.** See Rod.

**Pole, De la,** a family descended from William de la Pole, a Hull merchant, whose son Michael in 1383 became chancellor under Richard II., in 1385 was made Earl of Suffolk, and in 1389 died an exile in France. His grandson William (1396-1450) was the year before his death raised from Earl to be Duke of Suffolk, having since 1445 been practically prime-minister to King Henry VI. He was a disaster to the nation; and he was on his way to a five years' banishment in Flanders, when he was captured by a ship sent after him, and beheaded. John de la Pole, Duke of Suffolk (died 1491), married Elizabeth, sister to Edward IV. and Richard III., and from his son John, Earl of Lincoln (died 1487), Edmund, Earl of Suffolk (executed by Henry VIII., 1513), two churchmen, four daughters, and Richard, on whose death at the battle of Pavia in 1525 the line became extinct.

**Pole, Reginald, 'Cardinal of England,' was the son of Sir Richard Pole, and Margaret, Countess of Salisbury, the daughter of the Duke of Clarence and niece of Edward IV. He was born in Staffordshire, March 1503. He received the rudiments of his education from the Carthusians at West Sheen, and at the age of twelve went to Pagans, Oxford University, and was afterwards proceeded to Padua. He returned to England in 1523. He was then high in Henry's favour, while Queen Catharine was much attached to his mother. Pole's position, when the question of the king's divorce was raised, became a difficult one. He appeared at first disposed to take the king's side. In 1530 we find him in Paris endeavouring to obtain from the university a decision favourable to the divorce, but shortly afterwards he became a convert of Cranmer, refused the archbishopric of York which was offered to him on the death of Wolsey, and renounced the king upon the course he was pursuing. Henry, however, made no open quarrel with him; and Pole left England in 1532, and after a short stay at Avignon travelled to France, and there bore his name and his weight with both men of learning and piety—Sadolet, Contarini, Morone, Flamino, Priuli, and others—who were urgent for an internal reformation of the church, and whose views on justification by faith and grace were approximating closely to the doctrine of Luther. Pole still retained his English ecclesiastical revenues, and made no hostile demonstrations against Henry, but in 1533 he entered into a political correspondence with the Emperor Charles V. Pole was now completely by Henry to declare himself, which he did in a violent letter addressed to the king, afterwards famous in its revised form as the treatise De Unitate Ecclesiastica. The king withdrew Pole's pension and prebends. Paul III., on the other hand, made him a cardinal (22d December 1538), and sent him to the Low Countries to confer there with agents of the English malcontents. Henry retaliated by causing a bill of attainder to be passed against him, and by setting a price on his head. His mother, with other relatives, was thrown into the Tower. He was received in Brussels by the Emperor, and was made a cardinal, and subsequently beheaded. Pole's diplomatic career was not, however, a brilliant one. His several attempts to procure the invasion of England were not successful. From 1539 to 1542 he acted as governor of the 'Patrimony of St Peter,' of which Viterbo was the capital. He took an active part in the discussions on the Interim, and when the Council of Trent was opened in 1545, he was one of the three cardinals who acted as legate-presidents. In the conciliar session of 1541, in 1549, Pole was at one moment on the point of being elected pope; after the election of Del Monte, as Julius III., he lived in retirement at a Benedictine monastery at Maguzzano on the lake of Garda, until the death of Edward V. He then proceeded to England as legato a latere, to assist Queen Mary in the reconciliation of the kingdom to the Church of Rome.

Pole was still only in deacon's orders, and had not abandoned the idea which he had apparently entertained, of an active part in the southern Marches of Tudor. The queen for a moment considered the project of obtaining a dispensation for this union with favour, but the influence of Charles V. pre-
POLENTA

vailed in favour of his son Philip. The emperor's fear of Pole's interference or precipitancy led to the legate being prohibited from continuing English for Pole. Philip was married July 25, 1554. Pole's attainder was removed by parliament, November 22, and two days later he arrived in London. He was provided with ample powers to allow the owners of the confiscated church property to retain their possessions, a condition which was understood to be absolutely necessary to secure the submission of parliament. On the 30th Pole solemnly dissolved the Houses of Parliament and country from their schism, and reconciled the Church of England to Rome. As long as Cranmer lived Pole would not accept a provincial archbishopric at Canterbury, although the see was vacant by the former's degradation, but after Cranmer was burnt Pole was ordained priest, 26th March 1556, and on the 22nd consecrated archbishop. In the meantime Giovanni Pietro Caraffa, once a friend of Pole and afterwards his bitter enemy, had become (May 1555) Pope Paul IV. The pope was indignant at the concessions made by the authority of his predecessor to the holders of church property, and he revived the accusations of heresy which had been in former days brought against Pole, both on the ground of his heresy and on his sympathies with the papal governor at Viterbo, and of his well-known opinions on justification. Paul IV. was, moreover, now at war with Spain, and could not tolerate Pole as his ambassador at the court of Philip and Mary in England. The cardinal's legation was accordingly cancelled, and he was summoned before the Inquisition, into the prisons of which the pope had already thrown Pole's friend the Cardinal Morone. Mary angrily protested, and the pope somewhat relented. He would not reinstate Pole, but appointed William Peto, a Franciscan friar, as cardinal legate in his place. The queen gave orders that the papal messenger bearing the hat should be stopped at Calais, and Peto died without receiving it. When peace was made between the pope and Spain, Paul still refused to reinstate Pole as his legate, and he did not withdraw the odious and unjust accusations of heresy. When the queen died, 17th November 1558, Pole, whose health had been long feeble, was lying dangerously ill. The impending failure of all his hopes no doubt hastened his end. He died on the following day, sixteen hours after the queen, in his fifty-eighth year.

It has been a disputed question how far Pole was responsible for Mary's persecution of Protestants. His leniency towards heretics in Italy had even brought him into trouble. Nevertheless it is remarkable that after Philip's departure from England and Gardiner's death (November 1555), when Pole became the queen's supreme adviser and her inseparable companion, the persecution increased in violence. If it was not instigated by Pole, it could not have continued without his sanction and support. In his diocese of Canterbury he issued in the first year of the reign an edict against heretics, and in July he delivered over to the secular arm five persons, who were burnt alive at Canterbury a week before his death.

Besides the above-mentioned De Unitate, Pole was the author of De Concilio (Rome, 1502), De summis Pontificum officiis (Rome, 1503), and De Austriaco Leone (Louvain, 1569). His letters, with a life prefixed, were published by Quirini (Brescia, 1744). Beccatelli's life of Pole, originally written in Italian, was published in a Latin translation by C. F. B. I. in 1690, and an English translation by B. Pye in 1706. The first edition of Phillippus' life, which occasioned much controversy, appeared in 1764-67. The fullest recent life of Pole is that by Hook, vol. i. and 2d. (London, 1798). See English Church History, Commentaries, Banke's Lives of the Popes, Froude's History, and Dixon's History of the Church of England, vol. iv.

**POLENTA**

Pole-axe (originally pollax, from poll, 'the head,' and axe; see BATTLE AXE.

Polecat, or Fitchet (Mustela putorius, or Fitchet) is a quadruped of the Weasel family (Mustelidae), and commonly referred to the same genus with the weasel, stoat or ermine, &c. It is the largest of the six British species of that genus, the length of the head and body being about 17 inches, the length of the tail more than 6 inches, the form stouter than that of the weasel or of the ermine. Its colour is a deep blackish brown; the head, tail, and feet almost black, the under parts yellowish, the ears edged with white, and a whitish space round the muzzle. The hair is of two kinds—a short woolly fur, which is pale yellow, or somewhat tawny, and long shining hairs of a rich black or brownish-black colour, which are most numerous on the darkest parts. The nose is sharp, the ears short and round, the tail pretty equally covered with longish hair. There is a pouch or follicle under the tail, which exudes a yellowish, creamy substance of a very fetid odour; and this odour is particularly strong when the animal is irritated or alarmed. Hence, apparently, its name *Foumart* ('Foul Marten'), which, with various provincial modifications, as *Fumart*, *Thoumart*, &c., is prevalent in most parts of Britain. The origin of the names Polecat and Fitchet is much more uncertain.

The polecat was much more common in Britain in former times than now, and is almost extirpated from some districts, through the constant war waged against it by game-keepers and others; and it is said that it is a veritable rat, bearing five, six, or even seven young at one birth. It is extremely destructive in the poultry-yard, the abundance present there inviting it to drink blood and eat brains, which seem to be its favourite luxuries. The rabbit is followed by the polecat into its burrow, and its ravages among poultry are partly compensated by its destruction of rats. The taming of the polecat does not seem to have been attempted. The smell prevents it. The skin is imported from the north of Europe under the name of *fitch*, and is used as a kind of fur, similar but inferior to that of the *Marten* (q. v., and see *Furs*). To artists the hair of the *fitch* or *fitchet* is well known as that of which their best brushes are made; the hairs used for this purpose being the long hairs already noticed, which grow through the lighter-coloured fur of the animal. The Ferret (q. v.) is supposed by some to be a mere variety of the polecat. A dark-coloured kind of ferret is commonly regarded as a cross between the polecat and the ferret, and is sometimes called the polecat-ferret.

**Polemoniaceae**, a natural order of plants, mostly herbaceous, allied to Convolvulaceae, and containing more than 100 known species, natives of temperate countries, and particularly abundant in the north-western parts of America. *Polemonium caruleum* is Jacob's Ladder (q. v.); *Phlox* is also of the order.

**Polenta**, an Italian dish, the chief ingredients of which are maize meal and salt. Sometimes wheat
or chestnut meal is used. It is made into a thick paste, cut into finger-like strips, and baked, generally with an addition of cheese. It is eaten either by itself or with roast liver or steamed meat and sauce. A similar dish, called Mamaliga, is eaten in Transylvania and Lower Hungary.

Poles (Gr. poleis, a ‘turning-point’), in Geography, are the two extremities of the axis round which the earth revolves; they are therefore situated the one on the north, and the other on the south side of the equator, and equidistant from all parts of it, or in 90° N. lat. and 90° S. lat. They are called the north and south poles of the Earth (q.v.).—In Astronomy the poles, which, for distinction, are frequently denominated ‘celestial poles,’ are those points in the heavens to which the earth’s axis is directed, and round which the heavens seem to revolve. The celestial poles are valuable points of reference to astronomers and geographers, so that the determination of their position in the heavens is of the utmost importance. Unfortunately, no stars mark their exact situation (see POLE-STAR)—though there is a minute telescopic star only a few seconds from the north pole, which may be employed instead of it in rough observations—and therefore it is necessary to seek some means for discovering its precise position. This is effected in the following manner: A bright star (generally the pole-star) is selected, and its position in its upper and its lower Cutsunations (q.v.) is accurately noted; the point midway between these two positions of the star is the pole of the heavens. The observation of the star’s two positions must be corrected for refraction, and it is for this reason that the pole-star is selected, since the effect of refraction is much the same in both positions of the star. The term ‘poles’ has, however, a wider application, also including the extremities of a line passing through the centre of a great circle perpendicular to its plane; thus, we have the poles of the horizon (viz. the zenith and nadir), the poles of the ecliptic, the poles of a meridian; and, in the same sense, the terrestrial and celestial poles of the heaven, as the poles of the equator and equinoctial respectively. Pole, in Physics, denotes those points of a body at which its attractive or repulsive energy is concentrated; see POLARITY, and MAGNETISM.

Pole-star, or Polaris, the nearest conspicuous star to the north pole of the celestial equator. The star which at the present time goes under the name of the pole-star is generally the main star of the constellation of Ursa Major. By examining attentively the general movement of the stars throughout a clear winter’s night, we obverse that they describe circles which are largest at the equator, and become smaller and smaller as we approach a certain point (the north pole of the celestial equator), close to which is the star above mentioned. This ‘pole-star’ is, however, a little less than 1° from the pole, and has a small but sensible motion round it. Owing to the motion of the pole of the celestial equator round that of the ecliptic (see PRECESSION), this star will in course of time (about 2100 A.D.) approach to within 28′ from the north pole, and will then recede from it. At the time of Hipparchus (150 B.C.) it was 12°, and in 1785 2′ 2″ from the north pole. Its place can easily be found in the heavens, for a line drawn through the stars Arcturus and Polaris (two pointers, from this peculiarity of the constellation Ursa Major, or the Great Bear, and produced northwards for about 4½ times its own length, will almost touch the pole-star. Two thousand years ago, in the place of the pole-star, there were two stars, and about 2300 years before the Christian era the star a in the constellation of the Dragon was not more than 10′ from the north pole; while 12,000 years after the present time the bright star Vega in Lyra will be within 5′ of it. See star-map at Ursa Major.

The south pole of the celestial equator is not similarly marked by the near neighbourhood of a bright star, the only star deserving the name of the south pole-star being of the sixth or least visible magnitude.

Pollautes. See TIBERGISE.

Police (Gr. politeia) is in modern times held to be synonymous with the whole body of men employed as constables, or with the system of administration under which such constables perform their duties in connection with the maintenance of law and order and the prevention and detection of crime. Originally, however, the politeia of the Greeks had a much wider signification, and what we now term force formed but a part of the regulation of the affairs of a state or country, which was the meaning of the original word. The Greeks, by the adoption of this term, says an old writer on police administration, apparently intended to indicate that the execution of those functions which were essential for the maintenance of that civil society which is the essence of every city, were two things inseparable from each other. The strictly executive character of police duties, however, as performed in Great Britain of the 19th century, was not always recognised in ancient times, as is governed by the English law, the district magistrate, who is ex officio head of the police within the limits of his jurisdiction, is also a judicial officer with extensive powers. In the capital of England itself, where the distinction between executive and magisterial functions is specially marked, the chief among these officials who were entrusted with police administration. It is difficult to refer to any country in which the separation of executive from judicial or magisterial functions has so strictly been carried out as would appear to be required under our modern interpretation of police duties. The French system of police, which is based on the old Roman administration, unites to a very considerable extent executive with judicial functions. The same remark applies to continental police administration generally; and even in the great dependency of India, a domain, by English law, the district magistrate, who is ex officio head of the police within the limits of his jurisdiction, is also a judicial officer with extensive powers. In the capital of England itself, where the distinction between executive and magisterial functions is specially marked, the chief among these officials is still, by virtue of his office, a justice of the peace, although the exercise of his powers in that capacity is restricted by certain conditions.

The existing system of police administration in the United Kingdom is of very recent origin; it arose within the 19th century, and in many instances was developed within the reign of Queen Victoria. In the early period of English history there was no such institution as a separate body of police. The responsibility for maintenance of the peace was imposed on each hundred or tithing, and the members of these divisions were held jointly liable for the consequences of any infraction of the laws which took place within their limits. Self-interest made every member of the association a constant, and although the collective responsibility of the tithing or hundred was for executive purposes represented by the headman of each, such transfer of liability was not recognised by the law when any penalty for breach of the peace was incurred. As time went on the business of the headman of the local division was taken by a constable or constables in the various villages or parishes of the country. In the larger towns the members of the various wards at first
maintained order and kept watch within their various limits; gradually separate watchmen, very inadequately paid, were introduced; but the inefficiency with which watch and ward duties were performed, and the impunity with which crimes were committed, were conspicuous, and in no place more than in the metropolis itself. During the 18th century spasmodic attempts were made to improve the administration in London, both as regards prevention and detection of crime. Horse patrols were introduced; a detective staff was organised; but the whole system was fragmentary and disjointed and the courts under which it was administered were manifestly unsatisfactory. The deprecatory of the old 'Charlies,' as the watchmen were called, and their inability to afford protection to the inhabitants of London, were proverbial; and as to Edinburgh we may read in the pages of the *Heart of Midlothian* Sir Walter Scott's description of 'that black banditti,' the 'City Guard,' who were in his days the 'alternate terror and derision of the petulant brood of the High School,' and objects of scorn to the citizens generally. At last in 1829 Sir Robert Peel constituted the Metropolitan Police, and the whole police system of the metropolis outside of the narrow limits of the City of London itself, and placing the control of the new force in the hands of the Secretary of State, Counties and boroughs followed suit in remodelling their police on the administrative principles adopted—save with reference to local control—by Sir Robert Peel in 1829, and since then the present system of police administration throughout the country has been developed on the lines of the original statute, 10 Geo. IV., chap. 44, amplified by 2 and 3 Vict. chap. 47. The new guardians of the peace in the metropolis, the constables, were of course, police-constables, and were in a sense a development of the tithing-man of old; but they resembled him even less than a member for a metropolitan borough resembles the burgesses who appeared before the chief-justices at Westminster with a statement of accounts in the reign of John. Yet the stages of growth are sufficiently well marked—from the responsibility of the tithing to the responsibility of its head, from the functions of the head board or tithing-man to the functions of the constable, from the election of a plurality of constables, to the election of a plurality of constables, and finally from a plurality of constables, deputy constables, and watchmen, under parochial or other local authority, to a plurality of constables under the central authority of a Secretary of State ("Pike's History of Crime in England, ii. 460").

In 1897 the police force in England and Wales had a total strength of 42,140 officers and men; in Scotland, 4,707; Ireland, 12,900. In 1891 the numbers were 37,657, 4194, and 13,977 in the three countries respectively; the total cost being about £2,500,000 a year. The proportion of police engaged in the maintenance of the peace, with reference to population and (b) to £10,000 of rateable value in the following cities and large towns, is as follows:

The above figures show that in determining the number of the police the authorities of each city and town have taken into consideration the varying needs and circumstances of each place, rather than to have aimed at subordinating their requirements to a theoretical proportion of police to population.

The police force throughout the country is in all respects a civil body. In the metropolis and in the larger towns it is of course necessary that the constables should be more or less drilled, to enable them when called on to act together in bodies, but the force is in its essence, constitution, and performance of duty, civil and non-military. In English police in London, they are called out by magistrates to supplement the police in the maintenance of law and order, but, thanks to the law-abiding character of the people, such occasions are of rare occurrence. The only branch of the force of which the constitution is more military than civil is the Royal Irish Constabulary, which will be noticed further on.

The control of the various police forces throughout the country rests with local authorities; the only exception to the rule being the Metropolitan Police, who remain, as they were originally designed to be, under the control of the Secretary of State. In England and in the larger counties and boroughs, police are provided by the counties and the boroughs, but in the smaller counties and boroughs the chief-justice of the peace is in charge. In Ireland the practice is the same, except that the chief justice of the peace is the agent of the Government through the Her Majesty's Secretary of State for the Home Department. On the continent of Europe the police forces still remain under the direct control of the state, and to a greater or less extent are frequently used for political purposes, as well as in the conservation of the public peace. In the United States (see below) the principle of local control is general, but in many of the larger cities police appointments are not altogether unconnected with services rendered to local politicians.

**Metropolitan Police.**—The total strength of the Metropolitan Police (exclusive of the City of London, which has a separate police force), as established by 2 and 3 Vict. chap. 47, extends over a radius of 15 miles from Charing Cross, and embraces a radius of about 700 sq. m. The population of the district may be estimated at not less than 53 millions; its acreage is about 441,000 acres; and the length of beats covered in the various streets, squares, and roads amounts to 8200 miles. Under 23 and 24 Vict. chap. 125, the Mayor of the metropolis is nominated by the Secretary of State, and employed in Her Majesty's dockyards and in the principal stations of the War Department. The cost of police per inhabitant is about 4s. 8d. Since 1868 the cost of the force has been limited to the proceeds of a 9d. rate on the rental assessed in the Metropolitan Police district, of which 4d., till 1889 contributed by the Treasury, is now paid by the county councils, out of the Exchequer Contribution Account, and 5d. by the parishes. In 1890 an annual sum of £160,000 was allotted out of the proceeds of the Local Taxation Act, to defray part of the expenses of the police force. The amount available for police purposes in the metropolis may be put down as the total proceeds of the 9d. rate under the original statute, plus £160,000.

That the police of the metropolis is a costly body is apparent. Not only is the population which the force is called on to protect enormous, but it is also exceptionally congested in many localities. The locomotion of such enormous masses of people develops difficulties in dealing with traffic unknown elsewhere. The annual charge for buildings, rent, and taxes is, and must be, higher than in other places, and the loss of small quantities of property by the police force is not merely with an exceptionally numerous and skilful class of criminals, but to secure the safety of the largest body of citizens in the world while engaged in their lawful occupations, creates sources of expense.
peculiar to London; indeed, so many circumstances, non-existent elsewhere, combine to render the administration of this force expensive that in no other community the headquarters’ office, which, not compared with that of even the largest cities and towns of the kingdom.

The system of administration is a development of the principle on which the force was first established by Sir Robert Peel—"unity of design and responsibility of its agents." The head-quarters, or the commissioner, who, acting under the immediate authority of the Secretary of State, is responsible for the administration of the system throughout the Metropolitan Police District. The commissioner is vested with the power of a justice of the peace for Middlesex and the City of London, but is debarred from acting in this capacity at general or quarter sessions, or in any manner out of sessions except for the preservation of the peace, or for the prevention of crimes generally. Under the commissioner are three assistant-commissioners, vested with powers of justices, two of whom deal with details of discipline and ordinary business, the third being specially entrusted with the control of the criminal department.

The whole of the Metropolitan Police District is marked off into two divisions, each having a force of several hundred men under the charge of a superintendent, aided by a chief-inspector, inspectors, and sergeants. The superintendent is responsible for all the details of police administration within his division. For executive purposes the divisions are subdivided into chief-constable districts, each district comprising several divisions, and being in charge of a superior officer termed chief-constable.

Attached to each of the exterior divisions is a force of mounted men, aggregating in all about 250. The services of these men are employed on occasions of processions, public meetings, and similar demonstrations, the mounted force are brought in and perform valuable service. The Thames or River Police are recruited from sailors, and patrol the river in boats and steam-launches. Each principal station is in direct communication by telegraph with the headquarters, which, since November 1890, has been situated on the Thames Embankment, and is known as New Scotland Yard; and between every divisional station and its subdivisions the same system of telegraphic communication is maintained. For the detection of crime a special staff of officers is located in each division. Local crime is dealt with by these officers; for the conduct of special cases a separate detective staff is maintained at headquarters, under the control of the superintendent of the Criminal Investigation Department, and the whole detective organisation is specially under the charge of the chief-constable of the Criminal Department and of one of the assistant-commissioners. The supervision of habitual criminals is specially looked after at headquarters by the Convict Superintendents. The strength of the detective department is above 300 men.

County and Borough Police.—The total number of county and borough police in Great Britain is:

<table>
<thead>
<tr>
<th>Counties</th>
<th>Boroughs</th>

<td>Scotland</td>
<td>1,597</td>
</tr>
</tbody>
</table>

All such police are under the control of local authorities. By the Local Government Acts of 1888 great changes were made as to the bodies entrusted with such control, and the county councils superseded in many instances the previous agencies for regulating police administration. With reference to counties, the control of the police is vested in a standing committee, consisting of an equal number of county councillors appointed by the quarter sessions and by the county council. In the case of cities and larger boroughs, which are termed county boroughs, the local councils retain the power which they formerly had, and smaller boroughs are treated as parts of the counties in which they are situated. The control of the police is vested by the quarter sessions of the county over the ‘City Police’ was in no way affected by the Local Government Acts of 1888. The cost of police, as before, is paid from rates levied in counties and boroughs, supplemented by a contribution from the ‘Exchequer Contribution Account’ of half the cost of pay and clothing of every force certified to be in an efficient condition. Such contribution was formerly made directly by the Treasury in aid of the local rate under the County and Borough Police Acts. Under the Local Government Acts of 1888, however, each sum, consisting of duties on local taxation, licences, and the probate duty, is now placed to the credit of the police account of the county fund in counties, and by the county councils disbursed to county police. In boroughs having a separate police force the amounts are paid to and expended by the local councils.

The chief executive officers of county and borough police forces, who are appointed by local authorities, are styled chief-constables; superintendents or chief-constables; and for inspection purposes, by the Act of 1882, are connected with the chief-constable of the county. In Scotland, two officers for the whole of England and Wales, and one for Scotland, are appointed by the Secretary of State. The system of administration in cities and large towns is based, as far as circumstances admit, on that which prevails in the Metropolitan Police District. In county districts concentration of the police is not required the duties are arranged to suit the requirements of each locality. Some of the more important railway companies employ a special staff of railway police.

Police in Ireland.—There are only two police forces in Ireland: the Dublin Metropolitan Police, which has jurisdiction within the limits of the capital, and the Royal Irish Constabulary, which, as an imperial force, performs police duty for the whole of the rest of Ireland. The Metropolitan Police of Dublin numbers 1214 men, under the command of a commissioner, and its administration is on the lines of the Metropolitan Police. The Royal Irish Constabulary is the only force in the kingdom which is practically on a military footing, and the members of which are armed, drilled, and disciplined as soldiers. Ordinary civil police duties, both in towns and counties, are performed by this force, but it is unfortunately too often that they are called upon to act as soldiers in cases of great disturbance. The chief-constable of the Royal Irish Constabulary is directly under the Irish government. It consists of 12,763 members, officers and men, and is commanded by an inspector-general. Under this officer is a deputy inspector-general, who again is aided by three assistant inspectors-general at headquarters. Each county is served by a chief-inspector of police, and counties again are subdivided into districts, over each of which a district inspector is placed. Below these officers come head-constables, sergeants, and constables, all trained to the use of arms, and disciplined as soldiers.

Police courts.—These may be termed courts of first instance for hearing criminal cases. In counties such courts are held by justices of the peace, sitting at either petty or special sessions; in boroughs by stipendiary magistrates, or by mem-
members of the local councils in their magisterial capacity. For the city of London there is one police-court held at the Mansion House, and presided over by the Lord Mayor or one of the aldermen. In the Metropolitan Police Bureau there are five police-court justices, each of whom is the chief of which is held at Bow Street by the chief-magistrate, assisted by two magistrates. To each of the other Metropolitan police-courts two stipendiary magistrates are attached. In Scotland sheriff-courts, both in towns and counties, dispose of a large number of minor cases committed to them. The number of criminal offenders convicted in 1890-98 was between 8000 and 8000 a year in England and Wales, between 1900 and 1700 a year in Scotland, and between 1500 and 1000 in Ireland.

**France.**—France is divided into two great branches—(1) The Police Judiciaire, whose business is to discover offenders, gather evidence against them, and hand them over to the proper tribunal (see FRANCE, Vol. IV. p. 776); (2) the Police Administrative, whose functions correspond more closely to those of the English police in maintaining order. They, however, (as police générale and police municipale), wider powers and more varied duties, having to superintend public meetings, inspect public food-supplies, administer the laws as to the publication of printed matter, the watching of watchmen, the prevention of thefts, examinations of morbid states, and to note the sale of arms. There is a special department of police politique. The armed police, with military organisation, on foot or mounted, known as gendamerie (21,000 men), together with gardes forestiers (8000) and gendarmes champêtres (21,000), are commissioners of justice (20,000), and the agents de police (14,000), belong to the judicial police. The nearest equivalents to English constables are the gardiens de la paix, formerly called sergents de ville, of whom Paris has some 6000. The Service de Sûreté is the detective department.

**United States.**—In the United States, where each state and each city has its own separate administration, the police system closely resembles that of England. The organisation of a uniformed municipal police is comparatively recent, even in the largest cities. New York, not substituted for the inefficient night-watch until 1845. The police organisation of that city may be taken as representative of the American system generally. The department of police of the city of New York consists of a board of police, comprising commissioners appointed by the mayor, and the 'police force' and officers appointed by the board. The city (with an area of about 82 square miles before the year 1897, and 359 square miles since) is divided into inspection districts, which are subdivided into precincts. At the head of the force is a superintendent, under whom there are inspectors, a captain over each precinct, sergeants, roundsmen (visiting officers), patrolmen (the body of the force), and doormen at the stations. There are also about a score of police surgeons. The general administration of the force is vested in the board of police who make appointments, transfers, &c., hear charges against members of the force, and make rules and regulations for the discipline of the department. The orders, however, must not conflict with the constitution of the Union or of the state. The superintendent is the chief executive officer, who is appointed by the board, to whom he makes written quarterly reports; and he receives similar quarterly reports in writing from each of the inspectors. The captains report every morning to the central office. The roundsmen must see that the patrolmen are properly performing their duty, and the sergeants again are responsible for both roundsmen and patrolmen. Besides the general force, there are several 'squads' organised for special duties. These include the 'sanitary police company,' whose members inspect buildings, premises, employments, ventilation, sewerage, &c., which are dangerous to health, or conducive to the spread of disease. They also visit lunatic asylums, report nuisances, and seize food unfit for consumption; officers of this company also act as school-board officers, and others, qualified as engineers, inspect steam-boats and stationary steam-boilers used for motive power in the city. The city also has several 'squad' officers, and others are the mounted squad for duty near Central Park, the mounted patrol for rural precincts, the harbour police, the 'police reserve' (for enforcing city ordinances), the Broadway squad (for aiding pedestrians in crossing the day), special service officers, and special officers who falls the duty of seeing that the streets are kept clean, and a bureau of street cleaning is appointed by the board to supervise this department. Another duty imposed upon the New York police relates to elections: all elections within the city are held under their supervision, and the votes are counted by the board, to whom the returns are transmitted. In 1897 the police force of New York was 3500 men, and of Brooklyn 12,000; and since the creation of 'Greater New York' in that year, the number of police has been proportionately increased.

**Australia.**—In the southern part of New South Wales the number of the police force is 1000; in Victoria, about as many; in South Australia, 500; in Queensland, 900; in Western Australia, 500; in Tasmania, 270; in New Zealand, 390.

See PRISON, JUSTICE OF THE PEACE; F. W. Maitland, Justice and Police (1882); Tiedemann, Police Power in the United States (1887); G. W. Hale, Police and Prison Discipline (1894).

**POLIGNAC,** an ancient French family, which claims to derive its name from a castle—the ancient *Apolliniacum*—in the department of Haute-Loire, and which since the 9th century possessed the district of Velay. Among its most famous members was Cardinal Melchior de Polignac (1661-1742), who was employed in diplomatic missions in Poland and at Rome, and received a cardinal's hat after acting as plenipotentiary of Louis XIV. at the peace of Utrecht (1712). On 4 July 1732 he was named minister of state, and the next year he was appointed Archbishop of Auch. Polignac succeeded Bossuet at the French Academy in 1704, and left unfinished the *Anti-Lucrétia* (1745), a poem intended for a rehabilitation of Lucretius. Some other members of the Polignac family are more notorious than noteworthy. In the reign of Louis XVI. Iolante-Martine Gabrielle de Palatson, Duchesse de Polignac (born 1749; died at Vienna, 9th December 1783), and her husband, Joseph Duc de Polignac (died at St. Petersburg, 1817), grand-nephew of the cardinal, were among the worst, but unhappily most favoured, advisers of Marie Antoinette. They obtained vast sums of the public money from their royal master and mistress, and were largely responsible for the extravagance of the court, and for the operations of the Duc de Polignac knew how they were hated, and were the first of the noblesse to emigrate. From the Empress Catharine of Russia the duke received an estate at St. Petersburg, and did not return to France at the Restoration.—His son, Auguste Jules Aimé de Polignac (1748-1817), who was ambassador at Versailles, 14th May 1780. On the Restoration he returned to France; became intimate with the Comte d'Artois, afterwards Charles X.; from his devotion to the policy of Rome received from the pope in 1820 the title of Prince; was appointed ambassador at the English court; and finally, in 1829, became head of the last Bourbon
ministry, in which capacity he promulgated the
ratal ordinances that cost Charles X. his throne.
He then attempted to flee, but was captured at
Granville on the 15th of August, was tried, and
carded to death on the scaffold in the Palace of
Ham, but was set at liberty by the amnesty of
1836. He took up his residence in England,
but died at St Germain, 2d March 1847. He was a
puzzle-headed man; 'a mere idiot' Guizot called
him to Bishop Wilberforce.—His son, Prince
Amherst (1812-90), was a leading monarchist.

Polishing. See French Polishing; also DIAMOND, GRAIN.

Polishing Slate, a mineral composed chiefly of
silica, with a little alumina, lime, oxide of iron,
and water; white, yellowish white, or yellow; and
of specific gravity about half that of water. It
is used for polishing glass, marble, and metals.

Politician. ANGELO POLIZIANO (Latinised Politianus) was
born at Montepulciano in Tusc-
any, on the 14th July 1525. His real name was
Ambrogini, but, in accordance with a common
practice at the Renaissance, he early called himself
by the Latinised form of his native town, which
Italianised into Poliziano is the name by which he
is known in his own country. His father, Bene-
detto, after the death of his own child, who was
assassinated by certain of his fellow-citizens, and
left his widow and five children so scantly pro-
vided for that, even after Angelo the eldest had
given the most signal proofs of his genius, he was
on the point of being taken from his studies and
put to a trade. At the age of ten he was sent to
Florence, then under Lorenzo de'Medici, the
brilliant centre of the Italian Renaissance.
Here he had as his teachers the most famous
scholars of his time, the Greeks Arcypophus and
Kallisto, and the Italians Landino and Ficino.
His progress in the ancient languages, the special
studies of the period, was extraordinary even in
that age of precocious talents. By his sixteenth
year he wrote epigrams in Latin and Greek that
excited the wonder of his teachers. At seventeen
he began the translation of the Iliad into Latin
hexameters, a work which it had been the ambition
of all the Italian humanists to achieve. The first
book had already been translated by another
scholar, and Politian at different periods carried
on the work to the end of the fifth. By his success
with the second book he was admitted into the Latin
circle of the 'Homeric youth,' and attracted the attention
of the great Lorenzo himself, who now stood his firm
friend and patron. Thus secure of a settled position
his life was thenceforward devoted to incessant
study, and he was soon recognised as the prince of
Italian scholars, and the most remarkable literary
genius of his time. At the age of thirty he became
professor of Greek and Latin in the university of
Florence, and the fame of his predications drew
students from every part of Europe, among whom
by his influence were the famous historians Bene-
lin, Grocyn, and Linacre may be specially mentioned.
Politian was also entrusted with the education of
Lorenzo's sons, Piero and Giovanni (afterwards Leo X.);
but their mother Clarice, who had ex-
cellent reason for doubting the genuine scholar-
ship of the director of her court, insisted on
his being removed from their immediate super-
tendence. In such occupation, varied by occa-
sional visits to other towns of Italy, Politian lived
at Fiesole in a villa assigned to him by Lorenzo,
who never left Florence. He died at Fiesole on
the 1st of February 1537. His death is the most
serious trial of his life, and he mourned his death in a
Latin elegy, which has been described as unique
alike in form and feeling in modern Latin poetry.
Two years later he himself died during the tem-
porary supremacy of Savonarola, whose religious
zeal was directed against every principle of
that pagan revival which it had been the life's work
of Lorenzo and Politian to forward. Politian's epi-
morphous was the first example of modern Latin
literature, and it is entirely in the ironical and sceptical spirit of that
movement of which he was so brilliant a repre-
sentative that its lofty closes any account of him-
self. It is as follows: 'Politian lies in this grave, the
angel who had one head and, what is new, three
tongues.'

Politian has the double distinction of being both
a scholar of the first rank and a poet of high merit
alike in Latin and in his mother tongue. Of
his industry as a scholar his translations of classical
authors (Eucletus, Herodotus, Hippocrates, Galen,
Plato's Charides, to mention a few of the long
series) are ample evidence, while his edition of the
Pandects of Justinian is regarded by modern
scholars as excellent even when tried by the latest
tests. His original works in Latin fill a thick and
closely-printed quarto, half of which is made up
of twelve books of letters, and the rest with his
poems in prose and verse. Among Neo-Latin
poets Politian holds perhaps the first place, his
peculiar distinction being that, while he is not
careful of classical purity, he has charged his verse
with a modern thought that is purely Italian, and he
was in Italian literature also he takes a high rank, both
in virtue of his own poetic production and as
having at a critical period given an impulse to the
cultivation of the Italian language. Before him
the Italian humanists regarded their native tongue
simply as a tool for the study of Latin, which, without serving the
needs of the people, but was beneath the attention of
scholars. The weight of Politian's name and example moved them to think differently, and
thereafterward Italian was secure of a place among
the other modern literatures. Of his productions
in Italian his Orfeo deserves special mention as
having been the first secular drama in the language.
As to his personal character, Politian had in full
measure the two great blemishes of the scholars
of the Revival of Letters, and notably those of Italy.
He was addicted to the lowest forms of vice, and
he knew no bounds to his abuse of those who had
the ill-fortune to offend him.

See Opera Ang. Politiani (Florence, 1499); Le Stanz, l'Orfo e le Rime di Messer Ano. Ambrogiati, illustrate da Giovan Carduccis (Florence, 1623); For accounts of Politian, see Biography of Life of Polizian', by J. A. Symonds, Renaissance in Italy, vol. ii.; Von Reumont, Lorenzo de'Medici (vol. ii. Eng. trans. 1876).

Political Economy is variously defined. According to the definition most generally accepted
in England, it is the science which is concerned
with the production, distribution, and exchange
of wealth. In Professor Marshall's Principles of
Economics it is defined as 'a study of man's
actions in the ordinary business of life; it inquires
how he gets his income, and how he spends it.'
The name 'The Elements of Political Economy'
dated only from 1615, having been first used (in this special sense, as
distinguished from domestic economy and moral
economy and from political theory) by Montelé-
tien de Vatteville in his Traite de L'Economie
Politique.

The science of political economy is a branch of the
study of man. Man is a creature with many
needs, which he seeks to satisfy by applying his
labour to the nature by which he is surrounded.
These needs are not a fixed quantity, but grow
and change with the development of society, as
man's devices for their satisfaction receive a cor-
responding development. In the growth of these
needs and of the devices to satisfy them we can
trace the economic development of the human
race. Political economy may be regarded as the
systematic and comprehensive study of the phenomena connected therewith. There have been economic facts therefore ever since the origin of man; but there was no real science of political economy from Adam Smith and his forerunners in France in the 18th century. Science generally is the systematic study of facts which existed before the study began. Yet, while political economy did not exist as an independent and comprehensive branch of human knowledge before the 18th century, much attention was given to particular economic facts. Various economic problems had received great and serious attention.

The history of political economy naturally falls into three divisions, the ancient, the medieval, and the modern. We shall treat them briefly in their order.

(1) The Ancient Period. — As in other sciences, the first notable efforts in economic reflection were made by the ancient Greeks. The leading Greek thinkers who handled economic questions were Plato, Aristotle, and Xenophon, who represented the idealism of the ancient world; Aristotle, the exponent of scientific realism; and Xenophon, who expounded the plain common sense of his time and country. Of the problems which they treated with the insight peculiar to their race we may mention first those relating to the economic aspects of the origin of society; the division of labour; the function of money; economics of slavery, which they considered a natural thing; property and the related question of communism; the dependence of political change and of revolution on economic causes; the population question. On these and other subjects the teaching of the great Greek writers is most valuable; nor is its value lessened by the fact that their discussion of economic facts forms only a part of the science of politics. And, while the conditions of the modern world differ so vastly from the Greek world, the economic views of thinkers like Plato and Aristotle will always have an interest for us, inasmuch as the solid groundwork of human nature continues substantially the same through the changing conditions of history.

Greek economics had no special interest or originality. The main contribution of the Romans in connection with political economy was to give legal form to the prevalent ideas of property.

(2) The Medieval Period. — During this period there was little discussion on economic problems that could now be called scientific. The most interesting feature of the economic views that then existed was the influence exerted on them by Christian teaching. This influence was most profound and greatly affected also the economic thinking of subsequent times. The influence of Christianity was especially manifest in relation to the weak and oppressed classes. It tended to soften and then to abolish slavery and serfdom; it raised the position of women and gave a new refinement to family life; the care of the poor became a first duty of men and of human institutions. The ideas and institutions of property prevalent in the Roman world, which were often harsh, severe, and cruel, were corrected by the spiritual ethics of Christianity. To the struggling and half barbarous feudal world it taught a nobler life and a higher conception of duty in the economic as in other spheres. It was the medieval economy, for a great part, an exalted and exalted poverty and resignation. In their opposition to the rigorous ideas of property some of the Fathers even advocated communism. The medieval period was a time of confused struggle, in which Christian ethics were often opposed not only to the rough and warlike egoism of the feudal races, but to the harsh economic ideas that were incorporated in the Roman law.

(3) The Modern Period. — The feudal communities were superseded by centralised monarchies; and the new system of the army and of the state, one, being attended by important changes in other spheres. The church lost much of its power. The feudal nobles were transformed into courtiers. The feudal militia gave place to professional armies in the pay and in the immediate service of the monarch. For the barons or peers of the realm and of the court and other dependents of the centralising ruler it was necessary first of all to have a sufficient revenue. And, as the old revenue in kind was neither convenient nor effective, it was found particularly desirable to have a revenue in money. Accordingly, it is the greater pressing functions of the statesmanship of that time to foster and to secure an ample revenue in money. The rise of the Colonial System (q.v.) on the discovery of America and of the sea-route to India, the great expansion of commerce thence resulting, the growth of the great commercial and industrial towns, the banking system, all these were regarded as elements in the strength of the centralised state, and were made subservient to its policy. Under these circumstances it was natural that special attention should be paid to the balance of trade; and that taxation should be raised to secure for their own country a good balance of the precious metals. Thus it became a special note of economic theory to place an exaggerated value on the precious metals. The Mercantile System (q.v.) was an expression of this exaggeration in the sphere of political economy. Economists differ as to the precise meaning and application of the phrase, and indeed it had no very precise meaning or application. The meaning of the phrase will naturally vary according as we confine the application of it to the exaggeration to which it specifically relates or extend it to the whole system of which the exaggeration was a conspicuous feature. But there can be no doubt that the system grew out of the needs and circumstances of the time. Its chief expounders were Bacon and Montesquieu de Vattelville in France, Antonio Serra in Italy, and Thomas Man in England. In practical statesmanship it is associated chiefly with the great names of Cromwell and Colbert.

Even during the prevalence of the mercantile system a new way of thinking on economics had arisen in England and France. Its keynote was freedom, and it too was an organic part of the social and political evolution of the time. The expounder of the new system was Adam Smith, but he was only the chief representative and culminating point of a movement which had been growing for more than a century. In England men like Locke, Joshua Child, William Petty, and Dudley North had been struggling more or less successfully towards a similar point of view. In France the school of Physiocrats, headed by Quesnay, had taught many of the new ideas; in particular they had been set forth with perfect lucidity and conciseness by Turgot in his Réflexions sur la Formation et la Distribution des Richesses (1766). In fact, Turgot's little book might be regarded as the first scientific exposition of political economy. Adam Smith's achievement was to give the fittest form to ideas which were becoming current among merchants and manufacturers, and to make commerce and industry the basis of a theory of political economy. His Wealth of Nations was the first thorough and comprehensive exposition of the subject by a man who had ample leisure and capacity, a remarkable knowledge of history, and an idea of the economic truth that no one else could witness.
defined as a system of natural liberty. In view of
of the ill-judged or antiquated regulations of the
past he advocated liberty; and to all that was arti-
ficial in such regulation he opposed a natural order,
that following the will of Rousseau in the return
to nature from a perverted civilisation. Indeed,
both in his assertion of freedom and in the appeal
to nature, Smith was only applying to political
economy principles that were dominant in other
sphere of the post-Roussean era. H e was the
example of his predecessors, and showed himself in
harmony with the new era, in regarding labour as
the source of wealth. With regard to other
economic questions relating to capital, rent, in-
terest, etc. Smith has said much which,
though it has not always gained the assent of subsequent
historians, has at least had the merit of starting
important discussion. Smith's pre-eminence as an
economist lies in the fact that he summed up and
presented in lucid perspective the best economic
thought of the times preceding, while his writings
were the starting-point of all further development.
The greatness of Smith becomes all the more
apparent when we contrast him with his suc-
cessors, for in none of them do we see the same
combination of humanity, moderation, and open-
mindedness, fullness of knowledge, width of view,
and following the school of Adam Smith, adhered to
the same qualities, but he fully applied them only
to the elucidation of a single aspect of the subject,
the population question. In Ricardo the historic
factor almost disappears in the abstract; his theory
of rent, for which he has been most noted, is
particularly abstract and artificial, and has born
much overrated. The main body of J. S. Mill's
economic work was simply a restatement of the
traditional doctrine, and as an achievement for
his time cannot be compared with what Smith did
for the 18th century. His later editions, as well as
the later editions of his Political Economy show a
perception of the fresh problems which are opening
up to the economist, but he never brought his
economic system as a whole into harmony with his
new views. His economic writings represent a
process of transition in which the old was not
fused or transformed by the new.
The political economy of Adam Smith had great
influence on the continent of Europe. J. B. Say
in France, and Ran and Hermann in Germany,
followed Smith more or less faithfully. But
Smith's school has never been altogether rejected
his teaching, has also met with strong opposition.
His doctrines have been variously criticised as
being too abstract and individualistic, as incul-
cating selfishness, as based on doubtful theological
assumptions. It is a special objection that his
tendency to individualism and cosmopolitanism
prevents him from seeing the importance of the
nation as an element in economic development.
Here we find the most fundamental point of differ-
ence between the economics of Germany and of
England. France and Germany are not the same
circumstances of the two countries. The national
element found conspicuous expression in the sys-
tem of List, who has been followed by the Ameri-
can economist Carey, the gist of this doctrine
being that the political economy of each country is
constituted by the peculiar conditions of its national development; in other words, that
circumstances render protection necessary to the
national life and growth of Germany and the
United States.
In the school of political economy which has long
been most prevalent on the continent of Europe
is usually described as historical. It holds that
economic factors must be studied in the light of the
historic conditions of each time and country—condi-
tions legal, political, social, and ethical. The
historical school is a protest against abstractness
and absoluteness in economic science. No reason-
able adherent of the school would deny that there
are permanent factors in economies, but all would
assert that even the most permanent elements are
subject to continual variation. That being so,
much will depend on whether the economist is
disposed to dwell on the stable or the variable
elements in economic development. Roscher
was the founder of historical school. He and Adolf
Wagner are its greatest recent exponent representatives.
Their works are true to the leading principle of
the school; they are studies of economic principles
conducted with all the lights which a vast histori-
ical learning can supply. Schlicht's is more than
historical, and he has given ample recognition to
the evolution principle in his Bau und Leben des
Sozialen Körpers.
At present it will be generally admitted by
students of political economy that the subject is
in an unsettled and unsatisfactory condition.
Various explanations of this may be given, but
the real and substantial grounds must be found in
the following great facts which have emerged since
the time of Adam Smith, and which seem to
necessitate a reconstruction, or at least a large
modification, of the science.
(1) The great increase in the study of history,
and the application of the historical method to all
departments of inquiry. The charge of neglect-
ing the teachings of history can be urged justly
enough against many of Smith's school; against
Smith himself, it is most unfair. It would be
absurd to say that an age which produced Smith
and Gibbon was entirely lacking in the historical
spirit; both men are amongst the finest examples
of it that have appeared. Yet they were only
isolated instances of a method which has now
become universal among competent economists.
The comparative study of history, and especially of
historical institutions, has practically come into
existence since their time, and has thrown entirely
new light on the growth and working of economic
forces.
(2) The general acceptance of the theory of
evolution, especially as taught by Darwin. We
can now see that Smith's theory of natural liberty
really meant that individual struggle for existence
carried on within the limits prescribed by law
which call the competitive system; and that the pro-
teptive system of the exceptional European continent
is only a moment in the struggle for existence
carried on between vast organised communities
like France, Germany, and Russia. In the United
States it may be considered as a moment in the
struggle for a better national existence against the
industrial power of England,
(3) The industrial revolution, whereby hand
labour has been superseded by machinery, and
individual effort has given place to labour organised
in vast industrial and commercial undertakings,
which as factories, railway and shipping companies.
This revolution was just beginning when Adam
Smith wrote his Wealth of Nations, which was
published in the very year when Watt produced
the first effective steam-engine (1776). The change in
industrial technique and organisation have been
vastly greater since Adam Smith's time than they
were in the whole period between Aristotle and
Smith.
(4) The growth of democracy, which took a
fresh start with the American revolution also in
the same year, when the popular edition of the
Wealth of Nations, in 1776, to be followed thir-teen
years later by the great French Revolution of
1789.
(5) The increasing prominence of the social
question, of which we need not further speak here.
It cannot be said that the current English economies have given due recognition to any of the above facts. Professor Marshall's important Principles of Economics (1890), while it is learned, thorough, and progressive in tone, and does considerably show the influence of new movements, is still somewhat the child of the tradition. The only prominent thinkers who give due recognition to the evolution principle in economics are Herbert Spencer and Schille.

It will be clear that the old abstract economics, of which Ricardo was the signal example, is now being replaced by a more realistic science. Most students of the subject will admit that we can best comprehend the present if we consider it as having grown out of the past, and if we can throw any light on the future, we can do so only by studying both the past and the present. In other words, the great function of the economist is to collect and analyse facts and to inquire into the action of the forces, whatever they may be, that determine the economic well-being of mankind. His aim must be on the one hand to avoid a servile adherence to the historical method, through which the doctrine of economic laws is developed by too elaborate apparatus of historical learning; and on the other hand to avoid the assumption that the economic conditions of our own time and country are and must be normal for all other times and countries. While the main body of economic inquiry must be the collection and analysis of facts, the best and most fruitful achievements in political economy accomplished by men like Quesnay, Turgot, Adam Smith, and J. S. Mill have been in forwarding human progress. Thus the ethical or ideal element has not been excluded from political economy but made a part of its subject-matter. It has informed and inspired the science in its noblest efforts. While political economy must start from an adequate basis of facts supplied by the cognate or subsidiary sciences, geology, geography, statistics, history, it must own allegiance to the supreme science of ethics. Progress in economic science will move in harmony with and promote the social and moral progress of the human race.

Political economy may be regarded as concerned with a vast process which is incessantly going on. This process begins and ends with human beings. The subject matter of which is found to stimulate men to those efforts for their satisfaction which are termed labour. But labour can create nothing; it operates by utilising natural objects, or as economists briefly express it, the land, which includes mines and the sea as well as agricultural land. In the history of civilisation a vast system of appliances have, under the name of capital, been developed and accumulated by the labour, ingenuity, and foresight of men for more effective operation on nature; thus we have the three factors of production, land, labour, and capital.

The distribution of wealth prevails in the most advanced countries these three factors of production are supplied by as many different classes of individuals, whose relations to each other are determined by free competition. Hence it is that the problems connected with distribution attain to primary importance in political economy. The share of the results of production obtained by the owner of land is rent; the share of the capitalist is called profits, consisting of interest, wages of management, &c.; the share of the labourer is simply the product of his own labours.

One of the most marked features in the recent economic history of the world is the enormous development of the means of communication and transport both by sea and land. In former times the bulk of the produce of labour was locally consumed by the producers themselves. The growing utilisation of steam and electricity has given rise to the great markets of the world, or we should rather say, to a great world-market, in which the exchange of the most varied commodities is carried on. Exchange had long been an important department of economics; it is now a dominant one. Out of exchange are derived the problems of supply and demand, of price, of value. The medium of exchange is money, also involving a wide complex of questions—banking, credit, &c.

The final aim of the whole economic process is the satisfaction of the needs from which it started. This satisfaction is only achieved when the commodities which are produced, distributed, and exchanged, but that they are used up not only for enjoyment, but for the production and maintenance of human energies. All human activity, whether it be viewed as the activity of individuals or of the great organised communities, such as states and nations, must rest on an economic basis, and must be more or less limited by the economic resources which it can command. As wealth consists of commodities which are derived from external nature and transformed in the process of production, some part of the wealth produced is inevitably returned to nature in a greatly altered form. The subject of consumption has been much neglected by political economists. The utilisation of the materials returned to nature, which are often considered as mere waste, but which could be scientifically applied to the recuperation of the exhausted powers of nature, has also been greatly neglected in economic technique.

The vast process which we have thus briefly sketched is for the most part a private matter. It rests with each individual to determine how he shall rest in the present and in the future. There is also a large public sphere connected with the state, the municipality, and other local bodies. It has almost universally been admitted that the state must provide for defence, justice, education, the larger means of communication, &c., and the necessary revenue is mostly drawn from the wealth of the citizens under the name of taxation. An enlarging set of functions, connected with lighting, water-supply, police, and to some extent education, are generally performed by municipalities and other local bodies, the funds for these being styled rates. Many of the older forms of society were marked by stability or stagnation, and the economic conditions under which they existed underwent little change. Yet economic history has also been a record of development. Labour in particular has gone through a distinct succession of changes, through slavery, serfdom, and the guild system, into the present system of free labour. Discontent has always been the mother of progress, and it is obvious that the economic changes of the present and the future must largely proceed from the discontent of the labouring class, especially from their discontent with the present distributive condition. Hence a group of important questions connected with trade-unions, co-operation, socialism.

It should also be said that the economic process is an organic one, that each link of the chain is connected with every other, and that the whole process is intimately related to the entire social, political, artistic, moral, and religious development of mankind. One of the greatest dangers to political economy (as to other sciences) is the excessive and exclusive attention which many of its facts are studied in isolation from the other branches of the science, and from the cognate provinces of human knowledge.
POLITICAL OFFENCES

Political Offences are generally exempted from the crime of Extradition (q.v.), by which a government agrees to arrest and surrender persons who have broken the law of a foreign state. A political offence may be defined as an offence committed in carrying on a civil war or open insurrection. In November 1839 the English judges had to decide whether the Swiss government could demand the extradition of one Castioni, who was proved to have shot a member of the ministry during a revolution excited by the Liberals in the canton of Ticino. There was some evidence that the murder was committed by private persons, and that the judges held that his act was privati esse political, and gave him the benefit of the exception in the treaty. The Conspiracy Bill of 1858, introduced after Oarain's attempt on the life of Napoleon III., proposed to make conspiracy to murder a felony instead of a misdemeanour. It was intended to secure the French emperor against plotters in England, and caused the fall of Palmerston's government, as being contrary to English traditions. As between a government and its subjects political offences have often been treated with more severity as may be seen on the following pages in the Roman law relating to peritullio and lexu majestas. In France and Scotland the law of treason was framed on the model of those laws which had been made to protect the person and government of the crown from external attack and risk. The ancient Roman state; the old English law of treason was also extremely severe. In modern times the tendency is to treat offences against the state according to the ordinary principles of criminal law. There are, however, two kinds of crime which raise political questions of some interest. (1) Crimes committed in the territory of one state against the government of another. The Foreign Enlistment Acts were passed to enable the British government to deal with persons who levy troops and prepare armaments against a foreign government within British territory. Some members of authority have censured the American government for permitting Fenians within its jurisdiction to levy war against the British empire. (2) Crimes committed by persons who honestly think they have a grievance against a government of their own country. In such cases the political motive is not, in law, regarded as an excuse; if e.g. a member of parliament incites to a breach of the law, magistrates and prison authorities must deal with him as with any other offender. A humane government will often extend special indulgence to political offences. Whether such indulgence should be granted (whether e.g. an Irish member in prison should be exempted from ordinary prison rules) is a subject of discussion for not of legal right. The dynamiwhos who in 1882-83 attempted to the destruction of English public buildings were properly treated as mere criminals, without regard to any alleged political aims.

Politics (Gr. politis, 'city' or 'state'), that branch of ethics which has for its subject the proper model of a government and its tendency to secure its prosperity, peace, and safety, and to attain, as perfectly as possible, the ends of civil society. Among the subjects which political science embraces are the principles on which a government is founded, the hands in which the supreme power may be most safely lodged and vested, the rate and obligation of the governing and governed portions of society, the development and increase of the resources of the state, the protection of the rights and liberties of the citizens, the preservation of their morals, and the defence of the independence of the state against foreign invasion.

While the philosophy of government constitutes the science of politics, the art of politics consists in the application of that science to the individual circumstances of particular states. The ancient Greeks had no concept of politics with reference to an ideal perfect state, which each propounded according to his own speculative views, pointing out the variation of every existing government from his standard. The 'politics of a country' implies the course of its government, more especially in its relations with foreign nations, than in its constitution and institutions.

In the articles on the several countries a sketch of the constitution is in most cases given. See also AMBASSADOR, Anarchism, Anthropology, Aristocracy, Balance of Power, Cabinet, Congress, Democracy, England, History of Political Ideas, International Law, Nationalism, Parliament, Republic, Representation, Socialism, Tribe, Whigs and Tories, &c.; and the articles on the expounders of famous political theories—Plato, Aristotle, More, Machiavel, Bentham, Lassalle, Marx, &c.

Poliziano. See Politian.

Polk, James Knox, eleventh president of the United States, was born in Mecklenburg county, North Carolina, November 2, 1839. His ancestors, who bore the name of Pollock, emigrated from the County of Ireland to his father's grandfather in the 18th century, to the state of South Carolina, and to the state of Tennessee in 1825. He was educated in the University of North Carolina, and studied law with Felix Grundy of Tennessee, an eminent lawyer and statesman. Admitted to the bar in 1829, he was three years after elected a member of the legislature of Tennessee, and in 1835 returned to congress by the Democratic party. In 1835 he was chosen speaker of the House of Representatives, a position he filled during five sessions with firmness and ability. After serving fourteen years in congress, he was in 1832 elected governor of Tennessee; but he failed to secure re-election in 1841 and 1843. In 1844 he was nominated as a compromise candidate for the presidency, against Henry Clay, and elected by a popular majority of only 38,000, out of 175 electoral votes to 105. His cabinet included James Buchanan as secretary of state and Bancroft, the historian, as secretary of the navy. Polk's firm attitude with regard to the annexation of Texas had mainly secured his election, and he carried out the policy to which he was committed, with prudence and firmness. In his first message to congress, in December 1845, he announced that the western bank of the Nueces River, beyond which Texas had not exercised jurisdiction, was already occupied by American troops. On September 12th Texas was admitted to the Union; on the 31st jurisdiction was extended to the disputed territory beyond the Nueces.
These proceedings failing to goad the Mexicans into a declaration of war, the president forced on himself the responsibility of the situation by announcing the suggestion of General Taylor, to the Rio Grande. Palo Alto and Resaca followed, and the Mexican war was successfully started; the capital was taken in September, and its fall enabled the conquerors to dictate terms of peace, by which the United States acquired California and New Mexico.

During Polk’s term the Oregon boundary was settled by a compromise (49°) offered by England, though the party cry (‘Fifty-four-forty or fight’) which helped to elect him was a claim for the entire territory to 49° 40' N. lat. In 1846 a revenue tariff in force from 1827 to 1831, which included specific and minimum duties, was adopted—in the senate, however, only by the casting vote of Vice-president Dallas. Polk consistently denounced the anti-slavery agitation; he did not believe in the possibility of a United States all slave or all free, and considered the modus vivendi between North and South quite satisfactory. Having pledged himself to a single term of office, he refused a renomination, and retired to his home in Nashville, Tennessee, where he died three months afterwards, June 15, 1849. Polk was a man of habits, firm, both in business and religious character. He was devoted to the principles of the Democratic party of Jefferson and Jackson—state rights, a revenue tariff, independent treasury, and strict construction of the constitution.

See Life by J. S. Jenkins (1850), and a History of his administration, by Ennio B. Chase (1850).

Polk, Leonidas, the Antony Belknap of the Confederacy, was born at Raleigh, North Carolina, 10th April 1806. He was a cousin of President Polk, and grandson of Colonel Thomas Polk, an officer of the Revolution. Graduating at West Point in 1827, he received a commission in the artillery, but was induced to study for the ministry, and in 1830 received deacon’s and in 1831 priest’s orders in the Episcopal Church. In 1838 he was consecrated Bishop of Arkansas and Indian Territory, with charge of the dioceses of Alabama, Mississippi, and Louisiana; in 1841 he resigned all these except the bishopric of Louisiana, which he held until the Sixth November, 1843, or ten years, until his death. Soon after the outbreak of the civil war he was offered a major-generalship by Jefferson Davis, and, accepting it, proceeded to strongly fortify strategical points on the Mississippi. At Belmont, in November 1861, he was driven from his camp by Grant, but returned and eventually compelled him to retire. At Shiloh and at Corinth he commanded the 1st corps; in October 1862 he was promoted to lieutenant-general, and in November he conducted the retreat from Kentucky. After Chickamauga, where he commanded the right wing, he was relieved of his command, but in December 1863 he was appointed to the department of Alabama, Mississippi, and Eastern Louisiana, and he afterwards joined Johnston in opposing Sherman’s march to Atlanta. He was killed while reconnoitring on Pine Mountain, 14th June 1864, by a cannon-shot fired by some Northern officers who wished to give the bishop’s party a fright. See the Life by W. M. Polk (1894).

Polka, a species of dance, of Bohemian origin, invented in 1830, and introduced into England in 1843, the music to which is in 2 time, and has the rhythmical peculiarity of being accented on the third, fourth, and seventh measures.

Pollack (Gadus pollachius), a common fish on British coasts, belonging to the cod, haddock, and whiting genus. It is about the size of the coal-fish, is active in habit, and is frequently caught. The lower jaw projects beyond the upper, and there is no barbel. In Scotland and in some parts of Ireland it is called Lythe.

Pollaiuolo, Antonio, goldsmith, medalist, metal-caster, and painter, was born at Florence in 1439, and died at Rome in 1498, whether he had been summoned to cast a sepulchral monument for Pope Sixtus IV., and where he also cast a similar one for Pope Innocent VIII. (died 1492), both in St Peter’s, and both works of great merit. Antonio’s pieces—‘the best being ‘Hercules slaying the Hydra’, ‘Hercules destroying Antaeus’, and ‘St Sebastian’—are distinguished for the life and vigour of their drawing. His brother Pietro, born at Florence in 1448, and died at Rome in 1496, was generally associated with him in his work, though he devoted most attention to painting. To him are attributed an altarpiece introducing SS. James, Vincent, and Eustace (if indeed it is not mainly by the other brother), an Annunciation, a Coronation of the Virgin, and the Five Virtues.

Pollan (Coregonus pollan), a fresh-water fish of the family Salmonidae, a native of lakes in Ireland. It is particularly abundant in Lough Neagh, where great numbers are often netted, and sold in the neighbouring country. The fish is from 10 to 12 inches in length, and is well flavoured. See Coregonus.

Pollanarrua, a ruined city of Ceylon, 60 miles N.E. of Kandy, with a massive dagoba, a rock-cut temple, masses of sculptured stones, and a wide area of ruined buildings that attest the size and importance of the city, which became the capital of the kingdom about 770, after the Malabar invasion ruined Annadhunapura, the former capital. The city stood on the site of an immense tank, still called Topaweva or Topare. The place was first made known to Europeans in 1820.

Pollarding (to poll, to cut off, or shave the head) is the cutting off of the whole crown of a tree, leaving it to send out new branches from the top of the stem. Trees thus treated are called pollards. The new branches are never equal in magnitude to the original branches of the tree, although often more numerous, and when pollarding is often repeated the scars and stumps form a thick ring at the base of the tree, and the sapwood within branches spring. Pollards are not beautiful; but pollarding is practised with advantage in districts where fuel is scarce, the branches being cut off in order to be used for fuel, and the operation repeated every third or fourth year. Willows, poplars, alders, elms, oaks, and limes are the trees most frequently pollarded, chiefly for the sake of the bark of their branches, and the whole treatment very much resembles that of copse-wood. See COPE.

Pol len. See (under Flower) FERTILISATION OF the Flower; also the article STAMENS.

Pollio. Caius Asinius, an orator, poet, historian, and soldier, was born in Rome, 76 B.C. He sided with Caesar in the civil war 49 B.C., with Virgil at Pharsalia, and commanded in Spain against Sextus Pompeius, but was defeated. He sided with the triumvirs against the oligarchic senate, and was appointed by Antony to settle the veterans on the lands assigned them in Transpadane Gaul. It was then that he saved the property of the poet Virgil at Mantua from confiscation. After Antony and Octavian had quarrelled, it was Pollio who effected their temporary reconciliation at Brundisium (40). This year he was consul, when Virgil's fourth
POLL-TAX

1814-16, the Poll-tax was first established to raise funds for the Napoleonic Wars. It was unpopular and soon replaced by the Income Tax. After the defeat of Napoleon, the Poll-tax was abolished in 1842.

1742, a minor Scottish poet, was born in Glasgow. He studied at the University of Glasgow and the Divinity Hall of the Secessions Church, and was licensed to preach in 1827. He published his first book of poetry in 1832, titled Tales of the Covenanters anonymously before his poem. See the memoir by his brother (1843); Rosaline Masson. Pollak and Asytown (Famous Scots), 1890.

Pollok, a minor Scottish poet, was born in 1799 at Muirhouse, in the parish of Eaglesham, Renfrewshire. He studied at the university of Glasgow and the Divinity Hall of the Secessions Church, and was licensed to preach in 1827. He published his first book of poetry in 1832, titled Tales of the Covenanters anonymously before his poem. See the memoir by his brother (1843); Rosaline Masson. Pollak and Asytown (Famous Scots), 1890.

Pollokshaws, a manufacturing town of Renfrewshire, on the White Cart, 3 miles SSW. of Glasgow. It derives its name from the 'shaws' or woods of the estate of Pollak, held for more than six centuries by the Maxwells. It was made a burgh of barony in 1814; and its industries, first started in 1742, now comprise power-looms, bleaching, iron-founding, paper-making, &c. Pop. (1841) 4627; (1881) 9363; (1891) 10,228.

Poll-tax, or Capitation Tax, a tax levied by the poll or head (per capita). In England the imposition of a graduated poll-tax (varying from 4d. to £4, according to rank and wealth) in the time of Richard II. led to Wat Tyler's rebellion in 1381. A simple poll-tax was imposed in 1513; and an unpopular tax (varying from 12d. for a private person to £100 for a duke) was assessed in 1678 and abolished in 1688. In the United States most states impose a poll-tax or capitation tax as a poll-tax, or Capitation Tax, a tax levied by the poll or head (per capita). condition of the sufferage; the sun being generally $1, but in some states only 50 cents, and in others varying from year to year, but not exceeding $8. A considerable number have no such tax; in others the imposition of a poll-tax is expressly prohibited by the constitution. Tax.

Polo, an equestrian game, which may be shortly described as hockey on horseback. It is of oriental origin and of high antiquity; indeed, it has been claimed that it can be traced back to 600 B.C. The accompanying illustration is from a beautifully illuminated Persian MS. of the poems of Hafiz, executed in the year 956 of the Hegira or 1549 of the Christian era, and now in the Bodleian Library, Oxford, by the permission of whose standing what is required of them. It is part of the game so to ride alongside an opponent as to prevent him from hitting the ball, but it is not allowed to ride across in front of an opponent. To become a good player requires strength, good horsemanship, and a keen eye, as well as a sound

See Captain G. F. Youngusband's Polo in India (1890), and the chapter on 'Polo' by J. Moray Brown in Riding (Badminton Library, 1891.).

Polo, Marco, the greatest of medieval travelers, was born of a noble family of Dalmatian origin, at Venice, in 1254. His father, Niccolò Polo, and his uncle, Malteo Polo, both enterprising merchant-adventurers, went on a mercantile expedition, visiting Constantinople, the Crimea, and the court of Bura Khan at Samarkand. They first travelled round the north side of the Caspian Sea to Bokhara, and then fell in with some envoys returning from Hulagu in Persia to his brother the Great Khan Kubilai, and by them were persuaded to accompany them to Cathay. They were well received by Kubilai, then either at Cambaluc (Peking) or his summer residence at Shangtu (Coleridge's Xanadu), north of the Great Wall. He listened eagerly to their reports concerning the trade and government of the four empires, and commissioned them as envoys to the pope, bearing letters requesting him to send 100 Europeans learned in the sciences and arts, to act as instructors to the Mongols. They reached Venice in 1269, found Rome in the confusion of a long interregnum, and, after the new pope (Gregory X.) was elected, could only get two Dominicans, and even these had hardly commenced the journey when they lost heart and turned back. The Polos made their final start in the November of 1271, taking with them young Marco, and arrived again at the court of Kubilai Khan in the spring of 1275, after travelling by Sivas, Mosul, Bagdad, Hormuz, through Khurasan, up the Oxus to the Panir, by Kashgari, Yarkand, and Khotan, Lob Nor, and across the great desert of Gobi to Tungtu, thence to Shangtu. Their second reception was still more honourable than the first, and the Khan took special notice of Marco, from the rapidity with which he learned the customs and language of the Mongols. His wisdom and intelligence also recommended him as a fit envoy to the various neighbouring rulers; and during his residence at their several courts Marco observed with great care the manners of each country, and delivered on his return a detailed report to the khan. In various missions he visited the western provinces on the borders of Tibet, Yunnan, northern Burma (Mien), Karakorum, Champa or southern Cochin-China, and Southern India. For three years he served as governor of the town of Yung-chow, and with his uncle helped to reduce the city of Saiansfu by constructing mangonels for casting stones. The khan long refused to think of the Polos leaving his court, but at length in the beginning of 1295, obtaining permission to join the escort of a Mongol princess, who was travelling to marry Arghun, khan of Persia, grandson of Kubilai's brother Hulagu. They sailed from Chwai-chow in Fuki (Zaitian), but were detained long on the coasts of Indo-China, and finally reached Persia after two years had passed. Two of the three envoys and most of their attendants had perished. Arghun Khan himself was dead, but the three Polos and the young princess were safe, and she married the late khan's brother and successor, Arghun, as the daughter of the native city about the end of 1295, and Ramusio tells the story how like Ulysses they were recognised by none of their kinsfolk, and repulsed from the door. They brought with them much wealth in the portable form of precious stones, the fruits

authorities it has been specially photographed to illustrate this article. It bears the following legend: 'Welcome to the meddian, thou chief of horsemen: strike the ball.' Polo was first played by Europeans in 1863 in Calcutta, whither it had been brought by officers who had been stationed in Cashgar in Assam, where polo has been played since time immemorial by the hill-tribe of Manipur. Almost the same game exists in Tibet; whilst native equestrian games more or less closely resembling polo are played in Japan and other parts of the East. Since 1871 many polo clubs have been started in Britain and, since 1876, in America, as well as wherever Britons are found in the East. The principal British club, which makes the rules of the game, is at Hurlingham, near London. The following is a short description of polo: An oblong space of turf is marked out, of which the proper size is 300 yards by 200 yards; at each end in the centre of the line two poles are fixed 22 feet apart, forming the goals through which it is the object of the opposing sides to strike the ball. The players are mounted on ponies, the size of which has a definite place (numbered one, two, three, and back) in relation to friends and opponents; and in polo, as in most games, combination is perhaps the first condition of success. The ponies have to be carefully trained, and some acquire wonderful cleverness in under-
of their trading. In 1298 Marco fought his own galleys in the great battle of Curzola, in which the Venetians under Dandolo were defeated by the Genoese under Doris, and was taken prisoner and imprisoned for a year on the island of Rapallo; later, in about 1298, Marco dictated to another captive, one Rusticiano of Pisa, an account of his journey through the East. After his liberation he returned to Venice, where he died in 1324, and was buried in the church of S. Lorenzo. The traveller bore among his contemporaries the name of Marco Polo. In 1299 he published his Practica Monilien, most probably from his having frequently used that word in his attempts to describe the wealth and splendour of the khan. The wonders he narrated seem to have excited incredible—

even long after he left Venice. Boucicaut commends the circumspection of the reader who, "shall carry a wary eye on Paulus Venetus, Jovius, Olaus Magnus, Nicerbergins, and many others."

Marco Polo's book consists of two parts: (1) a Prologue, the only part containing personal narrative; (2) a long series of chapters descriptive of notable sights, manners of different states of Asia, especially that of Kublai Khan; and ends with a dull chronicle of the interminable wars of the House of Genghis during the second half of the 13th century. See Marco Polo succeeds in almost entirely eluding the intellective, his subject is how he consciously revealed to the eyes of his reader as a man truthful, brave, shrewd, keen-eyed, grave, of few words, fond of sport, with all the due respect of the prosperous man for wealth. He shows throughout a singular lack of humour—Sir Henry Yule's style is a good instance. But when he has to tell of so strange a custom as the conversation among the Gold-teeth on the frontier of Burma. He is no less sparing of scientific observations, and his geographical data are not infrequently the reverse of clear and adequate. He tells us that he acquired the language of every nation in the Mongol empire, and as many as four written characters, but of these Sir Henry Yule thinks Chinese was not one. His work is poorer in information relating to the Chinese proper than anywhere else. Thus, he does not mention the Great Wall, nor yet customs so striking and distinctive as the use of tea, the compressed feet of the ladies, the fishing concomitant, artificial egg-hatching, nor the printing of books. An absurd assertion has been made that block-printing was carried to Europe by our traveller, by him shown to one Panfilio Castald, from whom it was learned by John Fans, of Mainz; and indeed the printers of Lombardy, misled by patriotic feelings, have stultified themselves by erecting a statue at Feltre to Castald, "the illustrious inventor of movable printing types."

Polyanthus (Gr., 'many-flowered'), a kind of Primrose (q.v.), much prized and cultivated by florists. It is generally believed to be a variety of the Common Primrose (Primula vulgaris), produced by cultivation, in which an amulet of numerous Polyanthus.
flowers is supported on a common scape (leafless flower-stem), instead of each flower rising on its own stalk from the crown of the flower-cluster; a modification to which a tendency often appears in the wild plant itself. Thus in its habitat it somewhat resembles the cowslip and oxlip, whilst in the size of its flowers it is more like the common primrose; but instead of the pale uniformity of the wild plant it exhibits great variety of different shades and colours.

The subvarieties are innumerable, new ones being continually produced from seed, and of short duration. The seed is sown about midsummer, and flowers may be expected in abundance next year, if the young plants are properly protected. The first few years are the most difficult. Polyanthus loves shade and moisture more than its congener, the auricula. It is very hardy, and seldom suffers from the most severe winters. Fine kinds are preserved for a time by dividing the roots. The cultivation of the polyanthus is prosecuted with particular assiduity and success in England. For the Polyanthus Narcissus, see Narcissus.

Polybius, the Greek historian, was born about 204 B.C. at Megalopolis in Arcadia. From his father Lycurgas, one of the leading men of the Achaean League, he received valuable instruction in literature and science, and his early studies were interrupted by war. He was one of the 1000 noble Achaeans who, after the conquest of Macedonia in 168, were sent to Rome on the ground that the Achaeans had failed to assist the Romans against Perses. Without any trial the Greeks were detained in an honourable captivity. Polybius was the guest of L. Aemilius Paulus himself, and became the close friend of his son, Scipio Aemilianus, accompanying him in his military expeditions. Polybius in his turn derived much advantage from the protection and friendship of Scipio, who gave him access to public documents, and aided him in the collection of materials for his great historical work. In 151, after sixteen years in Italy, the surviving Achaean exiles were permitted by the Roman senate to return to Greece; Polybius, however, soon rejoined Scipio, followed him in his African campaign, and was present at the destruction of Carthage in 146. But the outbreak of war between the Achaean and Romans summoned him again to Greece, where he arrived soon after the taking of Corinth. All his influence was now exerted to procure from the conquerors favourable terms for the vanquished; and in his writings and discourses he overlooks several long journeys—to Asia Minor, Egypt, Upper Italy, southern France, and even Spain—where it has been supposed he witnessed the capture of Numantia by Scipio in 133. He died about 122 B.C.

His history, the design of which was to show how and why it was that all the civilized countries of the world fell under the dominion of Rome, includes the period between 220, where the history of Aratus concluded, and 146 B.C., the year when Corinth fell, and with it the independence of Greece. Much the greater part of the work has perished, and only about 9000 of the 300,000 words of the ancient manuscript have been preserved complete; but the plan of the whole work is fully known. Of the two parts into which it was divided the first (books i.-xxx.) ; the introductory books i. and ii. being a sketch of the earlier history of Rome) embraced a period of fifty years, commencing with the Second Punic War and the Social War in Greece, and concluding with the subjugation of the Kingdom of Macedon in 168. The last ten books deal with the years 148-146. The great merits of Polybius are the care with which he sifted his facts, and the evidence of truth, his breadth of view, and his sound judgment, which was materially assisted by his familiarity with political and military life. He was an excellent authority on the art of war. His tone is didactic, dull, and wearisome; he is too anxious to draw consequences and deduce lessons, and has been called 'the first pragmatician.' His method of exposition is careless, somewhat confused, and inartistic; his style, occasionally pithy, but usually dull to a degree, belongs to the period of beginning decadence.

Of the three authors which have not been preserved entire we possess merely fragments or extracts. Fragments were found by Cardinal Mai, and published as late as 1827. Valuable editions have been published by Schweighauser (1795-96; new ed. Oxford, 1831), Bekker (1844), Dindorf (1862-68; new ed. 1882), Hultsch (1868-72; 2d ed. 1888). The portion on the history of the Achaean league has been edited by W. W. Capes, and selections (based on Hultsch) by Strachan-Davidson (1888); there is a readable English translation by W. H. Shuckburgh (1889). See Mahaffy, The Greek World under Roman Swaty (1890); German works on Polybius by La Roche (1867) and Pichler (1880); and R. von Scalla, Die Schriften des Polybius (1899). Polybius was a follower of Cato the younger.

Polycarp, one of the 'Apostolic Fathers,' was bishop at Smyrna in proconsular Asia during the earlier half of the 2d century. He is an important name, for he bridges the little known and much controverted period lying between the age of his master the Apostle John and that of his own disciple Irenæus, and his testimony is the larger, clearer, and more valuable because of his rigid conservatism and lack of intellectual individuality. The 'Life' by Irenæus is utterly unworthy. All that is really known of Polycarp's origin is given by himself; from himself we know that he was born about 60 A.D., and probably of Christian parents. By the migration of apostles and others from doomed Jerusalem, Ephesus and the neighbouring districts became the new home of the faith, and there Polycarp was 'taught by Apostles,' John above all, and 'lived in familiar intercourse with many that had seen Christ' (Irenæus, Hœreses, iil. 3, 4). The further statement that he was appointed bishop in Smyrna by l'Apostles' ("by John"—Tertullian) is probably coloured by the later conception of the episcopate, but it is certain that he appears to have been head of the church from early manhood.

Among contemporaries he was intimate with Papia. More interesting is his brief intercourse with Ignatius, who, on his way from Antioch to martyrdom at Rome, made a short stay at Smyrna, where Polycarp and the church ministered to him. The tone of his Epistle to Polycarp, written shortly after from Troas, is that of a letter to one less experienced, if not younger, and less energetic than the writer, but high respect is paid to Polycarp's steadfastness, piety, and position. In consequence all that is lost which the apostles, the church and the churches to send messages to Antioch, the Philippians wrote to Polycarp asking that their letter to Antioch might be forwarded by the Smyrnaean messenger, at the same time inviting exhortation, and further asking for any of the 'sacred writings' that were藏着 that the Philippians might have Polycarp's Epistle to the Philippians, in which he accedes to their various requests, and solicits further news of Ignatius. His influence on a younger generation, and his importance as a faithful preserver of the apostolic tradition, are vividly depicted by his intercourse with Flavianus in his Epistle to Flavianus, quoted in Eusebius, Hist. Eccl. v. 20: 'I can tell the very place where the blessed Polycarp used to sit and discourse... Whatso-
ever things he had heard from them (John and others) about the Lord... Polygamy, as having received them from eye-witnesses of the life of the Word, would relate altogether in accordance with the wider range of the subject. On this point neither yielded to the other, yet their relations remained so cordial that Anicius allowed Polygamy to take his place in celebrating the eucharist (see Irenaeus quoted in Eusebius, Hist. Eccl. v. 24). After turning many Valentinians and Marcionites from their heresies by his preaching, the aged bishop returned to Smyrna, only to win the martyr's crown in a persecution which broke out during a great festival. Unsatiated with meaner victims, the mob called for Polygamy, 'the father of the Christians.' With true dignity and modesty he despised the man. Betrayed by his servant-boy, but offered his life by the proconsul if he will revile Christ, he answers: 'Fourscore and six years have I been His servant, and He hath done me no wrong. How then can I blaspheme My King, who hath saved me?' As the proconsul were over, a fire was substituted for death by wild beasts, and Jews vied with heathens in providing fuel. But the fire arched itself about the martyr, and he had to be despatched with a dagger. The graphic Letter of the Smyrnaeans tells the story of the martyrdom to the Philippians, and the chronological appendix to this letter has been elucidated by Waddington's skilful dating of the 'proconsul,' and his conclusions have been confirmed by the discovery of inscriptions relating to the 'high-priest,' also mentioned therein, so that the martyrdom may, with strong probability, be dated 29th February 155 A.D.

The only writing of Polygamy extant is the Epistle to the Philippian, incomplete in the original Greek, but complete in a Latin translation. Its genuineness has been assailed, but in itself, it is of great value for questions of the canon, the origin of the church, and the Ignatian Epistles. More New Testament phrases are here inviolate than are found in any other work of the time. The epistles and especially the appendices, given to Paul and his epistles by this disciple of John, tell heavily against Tübingen theories of the origin of the church and the canon. The letter bears so closely on the Ignatian Epistles that, while apart from it the external evidence for their genuineness is weak, with that evidence is very strong. The grounds, however, for assigning the epistles of Ignatius and Polygamy to the reign of Trajan are not beyond question, while among other things a certain reference to heresy in Polygamy's epistle would better accord with a time about 150 A.D., or even later.

For one of the best editions of the Epistle (first edited by Halloix in 1633 and frequently since), see Patrum Apostol. Opera (ed. Gehhardt, 22 vol. ii. 1876) for the date of the martyrdom, Waddington's Fastes des Provinces de Provence, 1872, and the Oxford Studia Biblica (1885 and 1890). But the best and most exhaustive work on all the parts of the subject is Lightfoot's Apostolic Fathers, part ii. (24 octavo vol. ii. 1883), and a scholarly, and able attempt is made by the Rev. J. M. Cotterill in the Cambridge Journal of Philology (1891) to atriute the extant epistle to Antiochus, a monk of St. Basil, which he supposed under the name of Polycrates. But the ground thus alleged under the name of Polycrates is still extant; 'if,' in Gibbon's phrase, 'what no one may be said to be extant,' a dull and feeble work entitled Πάνταδικα τί ἄξων ἀράβιστ, divided into 130 homilies.

Polycotyle'donous Plants are those whose embryos have more than two seed-leaves (cotyledons). Examples are found occasionally, or as monstrousities, among Dicotyledons, in the Pine (Pinus) group of the Conifere. The polycotyledonous condition is the normal one, and the cotyledons occur in whorls of from three to ten. Multiplication of cotyledons occurs in a few other groups of the Conifere. Sometimes the numerous cotyledons unite in pairs, and this leads to the suggestion that they originally sprang from two; but many botanists believe that the cotyledons arise as separate leaves.

Polyerates, 'tyrant' of Samos from about 336 B.C. to 322. He conquered several islands of the Arcipelago, and even some towns on the Asiatic mainland, waged war successfully against the inhabitants of Milletus, and defeated their allies, the Lesbians, in a great sea-fight. His intimate alliance with Amasis, king of Egypt, proves the importance in which this daring island-prince was held even by great monarchs. According to Herodotus these successes were mainly owing to the jealous gods must be preparing for so lucky a mortal, and wrote a letter to Polyerates, earnestly advising him to throw away the possession that he deemed most valuable, and thereby avert the stroke of the sibylline gods. Polyerates, in compliance with his friend's advice, sent a signet ring of marvellously beautiful workmanship into the sea, but next day a fisherman presented the tyrant with an unusually big fish that he had caught, and in its belly was found the identical ring. It was quite clear to Amasis now that Polyerates was a doomed man, and he immediately broke off the alliance. When Cambyses invaded Egypt (525) Polyerates sent him a contingent of forty ships, in which he placed all the Samians disaffected towards his tyranny, hoping they might never come back; but mutinying they returned to Samos, and made war against the tyrant, but without success. Hereupon they went to Sparta, and succeeded in securing the help of both Spartans and Corinthians. A triple force of Samians, Spartans, and Corinthians embarked for Samos, and Amasis hurried the nautical Polyerates became more powerful than ever; but Nemesis overtook her victim after all. Orestes, the Persian satrap of Sardis, had conceived a deadly hatred against Polyerates, and, having enticed the latter to visit him at Magnesia, appealed to his cupidity, he was crucified, and crucified Polyerates.

Polydipsia. See DIABETES.

Polygalaceae. See MILKWORTS.

Polygamous, a term applied to plants which bear both unisexual and hermaphrodite flowers, either on the same or on different individual plants. For example, the maple produces male, female, and hermaphrodite flowers on the same tree; while some wild-plums sometimes bear male, female, and other flowers, as well as hermaphrodite flowers.

Polygamy (Gr. poly, 'many,' gaimein, 'to marry') includes ethnologically the social arrangement by which one wife has many husbands, now usually termed Polyandry (q.v.), as well as that in which a man has or may have several or many wives. To the latter the term polygamy is, however, practically restricted. Formerly polygamy was thought to be probably the original type of the development which has culminated in the marriage relations of civilised peoples; that this is not so is suggested somewhat fully in the articles FAMILY and MARRIAGE.

Polygamy certainly obtained at one time over a very large area of the world's surface; in general it may be said still to be the rule not merely amongst most African races, but amongst the peoples, both
more and less civilised, of 'the East' generally, and to a certain extent in Australia and Polynesia, though it is rare amongst American Indians. That there are many cases of polygamy, even in countries (q.v.) has been always treated as sinful, and polygamy is a crime by the law of Christian states. Greeks and Romans did not practise polygamy within historical times; the ancient Germans were the only barbarians known to Tacitus who were content with a single wife; and even in the East polygamy has been ascribed to merchants and artisans. In China there is but one rightful wife in a household, though a man may, if he will, keep secondary wives or concubines.

In Christian countries, even in those where concubinage and adultery are lightly regarded and divorce very easily obtained, polygamy is dealt with as a criminal offence. In Britain and the United States Bigamy (q.v.) is severely punished; under the same head any polygamous union is included. Nevertheless there have occasionally been found divines to defend polygamy or something like it. The Anabaptists insisted on such freedom; Oehino (q.v.) wrote in defence of it. When in 1540 Philip the Magnanimous, the reforming landgrave of Hesse, resolved with the consent of his wife (then a confirmed invalid) to marry a second wife, Luther and Melanchthon approved the transaction; personal freedom through non-conformity were the doctors of theology; and Bucer (q.v.) promoted, approved, and witnessed the bigamous union. The first wife survived the second marriage for nine years. As late as 1667, when Catherine of Braganza miscarried, some Anglican divines suggested polygamy as the best way of securing a direct heir to the throne.

Morganatic Marriage (q.v.) and Handfasting (q.v.) greatly simplified divorce, and often preceded a more binding and legitimate union; but another union at the same time was not compatible with either. In 1780 the Rev. Martin Madan, chaplain to the Lock Hospital in London, started the world and raised a violent controversy by arguing in favour of polygamy as a means of diminishing prostitution and saving human souls from guilt; the work in which these views were advocated was called The New Cornhill, or a Treatise on Female Ruin (3 vols. 1789–81). In recent times the Mormons (q.v.) by their practice of polygamy created a troublesome question for the administrators of United States law; but in 1890 they agreed to cease from making plural marriages. It has always been a disgust to the missionaries when conversions were made with several wives desired but not. As a rule the convert was treated as married only to the first wife in point of date, and was required absolutely to put away all the others—a rule that was inevitably harsh and inequitable in its operation. Bishop Colenso determined to make the convert part from wives he had married in good faith; so did the American missionaries in Burmah; and M'Farlane, in Among the Cannibals in New Guinea (1888), says that he and the other missionaries of the London Missionary Society 'resolved not to interfere with such social relations in which the gospel had found the people of New Guinea.' See Anthropology, Family, Marriage, Harem, and the works cited there.

Polyglot (Gr. poly, 'many,' and glotta, 'tongue') means a collection of versions in different languages of the same work, but is almost exclusively used in reference to the Greek Bible. The Hexapla of Origen (q.v.) contained, besides the Greek text, several other Greek versions, but is not commonly reckoned among the polyglots. The most famous polyglots are (1) the Complutensian, published under the patronage of Cardinal, nail-; (2) the Antwerp Polyglot, printed at the Plantin press, at the cost of Philip II, of Spain, in 1569–72, edited by Arias Montanus; (3) the London Polyglot, edited by Le Jay in 1645, in 6 splendid volumes; and (4) the London Polyglot, edited by Brian Walton, in 6 vols. folio, 1654–57, and containing the Bible, or parts of it, in nine languages. Of modern works of this kind the most convenient is Bagster's Polyglot, published a successful number at London in 1831 (new eds. 1874, &c.), which gives the Old Testament in eight languages (Hebrew, Greek, Latin, English, German, Italian, French, and Spanish), and the New Testament in nine (the Syriac version being added).

Polygnotus, a Greek painter who flourished in the middle of the 6th century B.C., was born in the isle of Theseus, and belonged to a family of painters. He was a friend of the Athenian general Cinon, and is said to have been attached to his sister, Elpinice. His principal works were at Athens, at Delphi, and at Pterae. In the first-named city he executed paintings in the temple of Theseus; in the Stea Pokiele (or Painted Portico), the Greek Princes assembled to judge of the Violation of Cassandra by Ajax; in the temple of the Dioscuri, the Rape of the Daughters of Leucippos; and in the Propylean on the Acropolis, a series from the old Greek legends. At Pterae he is stated, in the temple of the Athena, Ulysses and the Slain Suitors of Penelope. His greatest work is said to have been in the Lesche, a court or peristyile at Delphi, built by the Cnidians, the walk of which he covered with a series representing the Wars of Troy and the Visit of Ulysses to the Goddesses, or the Return of Ulysses to Polygnotus was a great advance on any of his predecessors. He was the first who gave life, character, and expression to painting. Aristotle extols the dignity and beauty of his conceptions.

Polygon (Gr. poly, 'many,' gonia, 'corner'), a plane figure, bounded by a number of straight lines; it is convenient to consider plane figures whose bounding straight lines are more than four in number. Polygons of 5, 6, 7, 8, &c. sides are denominated pentagons, hexagons, heptagons, octagons, &c.; and when the number of sides exceeds twelve the figure is merely mentioned as a polygon of so many sides.

Polygonaceae, a natural order of plants, mostly herbs, including a few shrubs. The leaves are alternate, with stipules cohering around the stem, though sometimes reduced to a mere ring. The flowers are not infrequently unisexual; the fruit generally a nut, often triangular, the seed with several pericarpaceous albumens which have an economic importance in buckwheat. The genus Polygonum comprises numerous species, of which several are natives of Britain; in North America
twenty-five species are found east of the Missis-
sippi. Knot-grass (P. aviculare) is a very common
British weed, and is found in cultivated and waste
places in all parts of the world from the tropics to the
Arctic regions. The stems of *P. amphibium*, an inhabi-
tant of ponds and watery ditches all over
England, are used by the fisherman for angling. The Spotted Persiania (P. persicaria), a very common
weed on ditches and in waste places in Britain;
but the only species really important on this
account is that called Dyer's Buckwheat (*P. 
tinctorum*), a native of China, the cultivation of
which has been successfully introduced in France
and Flanders. It yields a blue dye scarcely inferior
to indigo. *P. orientale* has long been occasionally
cultivated in flower-gardens in Britain, and is
quite hardy, although a native of the West Indies.
The Bistort (q.v.) belongs to the genus. *Fagopyrum*
was cultivated for buckwheat, abundant
on the mountains of the north of India, affords
an excellent substitute for spinach. *Fagopyrum
exsultans*, or *Polygynum Fagopyrum* (Buck-
wheat), is cultivated for the sake of its fruit, which
fits with its name. The Buckwheat is found in
northern Europe. The Garden Sorrel (*Rumex
acclusa*) and some other species of Runnex have a
singular combination of properties in their roots
and in their leaves. In the former there is greater
or less astringency, due to the presence of tannic
and gallic acid; in the latter, used in dye
less acida-
lous, owing to their containing oxalic acid. Rumbarb
(q.v.) belongs to this natural order; so does the Dock
(q.v.). The root of *Pterococcus aphyllo*, a native of the
sandy steppes of Siberia, when cut exudes a clear
viscid gum similar to Tragacanth (q.v.), which
swells in water and forms a mass of a bright
yellow colour; it is eaten by the Kalmucks in
times of scarcity. Its fruit, which is acid, is eaten
to quench thirst. *Trifaria americana* and *T.
Bomplandiana*, both natives of South America, are
sometimes grown as ornamentals, and are called
Admiralty. It produces racemes of fruit somewhat resembling
grapes or currants, the nut being invested with the
large and fleshy segments of the calyx. The fruit
is sweetish and subacid, and is used for tarts.
Coccoboa wifera is the Seaside Grape (q.v.) of the
West Indies. See also CALLITOXUM.

**Polynhymnia**, one of the nine Muses (q.v.).

**Polymerism.** See ISOMERISM.

**Polynesia** (Gr. *poly*, 'many', *nēos*, 'island'),
a term applied collectively by some writers to all
the Pacific islands of strictly oceanic character—i.e.,
either of volcanic or coralline origin; by others
restricted to the eastern groups inhabited by the
brown Polynesian race. Here it will be taken in
the broader sense so as to include all the Pacific
islands, except the Phylvan, New Guinea, and
Australia, except Japan, the Kuriles, Alentians,
Queen Charlotte, Vancouver, Revillagigedo, and
Galapagos, which are geographical dependencies of
the surrounding Asiatic and American continents.
The term in the narrower sense, or *South
Polynesian* as they are also called, are distributed over a vast space,
stretching across a hundred degrees of longitude
from New Britain (140° E.) to Easter Island (109°
W.), and across seventy degrees of latitude from
Hawaii (22° N.) to Stewart Island at the southern
extremity of New Zealand (47° 20' S.). But the
aggregate extent of dry land in this boundless
expanse of some 11 million square miles scarcely
exceeds 170,000 sq. m., of which nearly two-thirds
are in the South Pacific Archipelago, and the rest
in the total population is probably less than
1,500,000. See the map at World, and also
the physical map at Australia.

Polynesia comprises the three broad divisions of Micronesia, Melanesia, and East Polynesia,
which are distinguished by their geographical position, and partly by ethnological conditions,
and each of which is again subdivided into several
secondary groups. Thus, Micronesia (*Gr. mikros*,
'small', *nēos*, 'island') lies in the extreme north-
west almost entirely north of the equator, and con-
forms exclusively of small volcanoes and atolls,
forming the five archipelagoes of the Marianas
(Ludrones), Pelew, (Palaoa), Carolines, Marshall,
and Gilbert, all inhabited by heterogeneous popula-
tions in which most of the oceanic and perhaps
some of the continental elements are represented.
So also Melanesia (*Gr. melanos*, 'black') lies in
the extreme west entirely south of the equator,
and consists mainly of comparatively large upraised
crystalline, coralline, and volcanic islands disposed
in parallel chains from north-west to south-east,
forming the following divisions: 1. The Fijian,
Bismarck (New Britain and New Ireland),
D'Entrecasteaux, Louisiade, Solomon, Santa Cruz,
Banks, New Hebrides, New Caledonia, Loyalty,
and Fiji, all inhabited by the Melanesian or dark
Oceanic race. Lastly, East Polynesia lies on both
sides of the equator, mainly east of a line drawn
from New Zealand between Fiji and Samoa to
Hawaii, and consists of the twelve volcanic and
coralline archipelagoes of Hawaii (Sandwich),
Phoenix, Elice, Tokelau, Sanoa, Tonga, Ker-
madec, Austral (Taluna), Cook, Tahiti, Tuamotu
(Parimau), and Marquesas. Besides the large sedimentary and igneous region of New Zealand
and numerous sporadic islets, such as Norfolk,
Chatham, Rapaki, Easter, Manihiki, Tongareva,
Uvea, and many others. This division is the
most richly and variously peopled, and by recent white
migrants, of the large brown race, commonly called
'Polynesians' in a special sense.

Subjoined is a table of these multitudinous
island groups, with their areas, populations,
and political status.

</table>
POLYNESIA

Lying almost entirely within the tropics, and consisting nearly everywhere of igneous or coraline groups exposed to the same atmospheric and marine currents, Polynesia presents great uniformity in its climatic and biological conditions. In these respects, however, New Zealand belongs to a separate world, thanks to its large extent, lofty ranges, different geological history, and high southern latitude. But even in Fiji, Tahiti, Samoa, the Solomon and Hawaiian groups, with volcanic cones ranging from 1000 to nearly 14,000 feet, less variety is presented by the different local floras than might be expected from their great altitudes, compared with the prevailing world trade winds which are the moist south-east trades, which in summer veer round to the west and north-west. But these winds also bring moisture-bearing clouds, so that the rainfall is generally high, in the Solomon's excessive (150 inches), in Hawaii 60 to 80, and in New Caledonia over 40. But many of the atolls, being too low to arrest the currents, receive very little moisture, and in some places constitute a rainless zone, as indicated by the accumulated deposits of guano. The mean temperature is about 70° F. both in Hawaii and New Caledonia (about the same as on the equator from 5° S. to 10° N. to 90° F. But the climate, except in New Caledonia and New Zealand, is everywhere relaxing, and in the Solomons and other large islands malarias up to considerable altitudes.

In the coraline groups the flora is essentially oceanic, the prevailing species being the cocoa-nut and one or two other palms, the pandanus and bread-fruit tree, and such edible roots as yams, taro, and sweet potatoes. Besides these forms, the large archipelagoes have a rich forest vegetation, mostly belonging to the Papuanian and Australian zones, with some American and Pacific elements. Hence the prevalence of casuarinas, drimmaras, araucarias, tree-ferns, besides myrtles, ebony, and the banyan fig. Highly specialised forms are the New Caledonian niaudi (Melaleuca lanceolata), which yields the cajetut-oil, and the Hawaiian olenhons kula and gigantic kulaepo (Branch.)

In contrast with the relatively rich flora is the remarkably scanty fauna. The dog and pig were found both in the Solomons and Hawaii at the time of their discovery; but both appear to have been introduced in comparatively recent times. The only undoubtedly indigenous mammals in these and the other Polynesian groups are two or three species of rodents (rats and mice) and a few varieties of the bat family. Even reptiles and insects are rare, being chiefly represented by three small lizards in Hawaii, one snake, one scorpion, one centipede, and a spider in New Caledonia, a few snakes and frogs in Fiji, and in Hawaii a few snakes, one centipede. Fiji is the easternmost limit of the frog and the Solomons of the crocodile, which here adapts itself both to fresh and salt water about the rivers and estuaries. Birds are everywhere more numerous, 107 species occurring in New Caledonia, 46 in Hawaii, 30 in the Carolines, generally only ten in Tahiti. The 80 (Moho nobiltis), whose lovely black and yellow plumage is used for decorating royal mantles.

In recent times no branch of ethnology has been more carefully studied than that which deals with the origin, migrations, physical features, languages, and customs of these islands, and the intricate are their mutual relations that the difficult anthropological and linguistic problems suggested by a comparative study of these peoples are still far from solved. There is, however, a general consensus that Polynesia has been occupied from prehistoric times by two distinct races, the dark Melanesians, who belong to the same stock as the Papuans of New Guinea and Malaysia, and the brown Polynesians, called also Mahor and Savaior, whose racial affinities have not been satisfactorily determined. By different writers they have been classed to the Mongolian, Malays to the Aryans, Caucausians, to the American aborigines, and even to the Melanesians. But the difference between the Polynesians and Melanesians must be regarded as fundamental. The former are brachycephalians (round-headed, with high cephalic index), orthocephalians (with a flat head), dolichocephalians (long-headed, with the lowest cephalic index of any race), prognathous, broad-nosed, of a sooty black colour, with low orbits, black frizzly hair, and low stature (mean height, 5 feet 5 inches). The Melanesians are dolicocephalians (long-headed, with the lowest cephalic index of any race), prognathous, broad-nosed, of a sooty black colour, with low orbits, black frizzly hair, and low stature (mean height, 5 feet 5 inches).

The Polynesians, who closely resemble the Indonesians of the Malay Archipelago (see MALAYS), seem to be later arrivals almost certainly from Malaysia to Samoa, whence they gradually spread from island to island in a series of migrations. After the Polynesians, more recently sending colonies westwards to Melanesia and even to New Guinea. Hence Savaior settlements and mixed Savaior-Melanesian communities are now found in the eastern parts of Fiji, in the New Hebrides (Ninot, Fatuna, Mel, and Fili), in the Loyalty group (Uvea), in British New Guinea (Motu), and generally in Micronesia. That Samoa was the centre of dispersion is shown by the recurrence of such geographical terms as Samoan and Savaii (originally Savai), the largest island of the archipelago, under a title of common use, and the American Hawaii, Haivaiki, Haivaiki, Aivaiki), either in the geographical nomenclature or in the traditions and mythologies of all the Polynesian islands from New Zealand to Hawaii.

In Easter Island (Rapanui) and the Carolines (Ponape, Lele, Ualan) are found many cyclical monuments, with monolithic pedestals, stone avenues, ramparts or walls of basalt blocks over 30 feet long, brought from great distances. None of the present races could erect such structures as these, all memory of which has died out. They have been erected in the same way by the ancient peoples of America, and the features of the Easter Island (q.v.) statues are said to resemble the Balivan Aymarans, though others have recognised a Papuan cast in the specimens preserved in the British Museum. Skulls of a Papuan type have been found in the Carolines, and in the Tahitians the monuments were erected by these natives, it must have been under the direction of builders such as the Hindu missionaries who raised the stupendous temples of Java and Indo-China by training Mahay and Cambodian craftsmen for the work. The Polynesian languages appear to be members of the great Malayo-Polynesian family, which stretches across two oceans, from Madagascar to Rapanui. However it is to be explained, the fact is now established that both the dark and
brown peoples speak idioms derived from a common stock; and Mr. Colrington has even shown that the Melanesian are of a more archaic type than the Polynesian tongues. Perhaps this is the most inexplicable of all the problems presented by the Oceanic peoples, for here anthropology and philology are found to be in direct antagonism. An air of mystery appears as the theory has imposed its speech on the higher race, by whom it became profoundly modified both in its phonetic system and grammatical structure. But the reverse and less violent process is conceivable, and it may be seen in the blending of their own migrations over the Pacific that the more surprising fact that the intelligent Polynesians transmitted their speech to the more passive Melanesians at a very remote period, the former afterwards modifying it in the direction of greater simplicity and harmony, the latter preserving it in its more pristine inflectional form.

For over a century the Oceanic peoples have been in contact with Europeans, and nearly all the Polynesians, as well as many of the Melanesians, profess some form of Christianity—the first mission established by the Society Church was in 1797 (Cook's visit)—but the history of that Mission is left in the hands of the London Missionary Society. But as western influences increase the races themselves appear to decrease. Thus, the population of Hawaii had fallen from about 300,000 at the time of Cook's visit (1778) to 40,000 in 1854; the Maoris of New Zealand, from 400,000 in 1769 (Cook's first visit), were reduced to 42,000, including half-castes, in 1886, and the Tahitians from 240,000 in 1776 to less than 10,000 in 1888. Here and there the returns show an apparent increase, as in some of the Ellice and Marshall islands, but these are half-castes. Everywhere the pure Polynesian race seems to be rapidly disappearing, a phenomenon attributed partly to the introduction of alcoholic drinks, partly to the abrupt change of habits, dress, diet, &c. enforced or encouraged by the missionaries, but mainly to the ravages of leprosy, smallpox, syphilis, measles, and especially pulmonary affections, by which whole communities have been decimated.

Formerly the political organisation was based on a distinction between two classes, the nobles and the commoners. The Maoris of New Zealand have a system of democracy; but elsewhere the archipelagoes constituted one or more monarchies of a somewhat feudal character, with powerful hereditary rulers under a king, whose authority had been much reduced in Samoa, the Marquesas, and the other islands. Their subjects were gay, pleasure-loving people, engaged chiefly in fishing, agriculture, and navigation. Their diet was largely vegetarian (yams, taro, bananas, cocoa-nuts, &c.), varied with fish, pork, poultry, and, in some places, human flesh. Human victims were also offered on solemn occasions, and a prominent feature of the primitive religion was the so-called Tabu (q.v.), in virtue of which certain persons and objects acquired a sacred character. But there was nowhere a distinct sacerdotal class, and most of the old beliefs had resolved themselves into a system of ancestor-worship. Other distinctive institutions were certain orders of knighthood, secret societies with peculiar semi-religious rites, and tattooing, which, especially in Micronesia, acquired the character of a fine art and resulted in systems of Japanese systems in its elaborate designs and skilful execution. Few other arts were practised, and letters were unknown, although a national folklore, tolerably rich in historic legends and myths, was orally preserved, and has now been mainly recorded by scholars and missionaries. See CORAL, and the articles on the several Polynesian islands or groups of islands; and for the first navigators in Polynesia, see GEOGRAPHY, PACIFIC OCEAN.

Polyn., a name usually applied to an animal like the fresh-water Hydra or like the Sea-anemone, having a tubular body and a wreath of many tentacles around the mouth. The name is equally applicable to an isolated individual or to a member (zoon or person') of a colony. Thus, the individuals which make up a zoophyte or a coral colony are called polyps, and the term is seldom used except in reference to Cenolateral animals. But the Greek and Latin work on natural history the term polygon or polygonus is usually applied to the octopus (poulpe), or some other cuttle-fish, though sometimes to the many-footed wood-locust, Ommus. Réanemur and Jussieu were the first to apply the word to zoophytes and the like; Lamarck used it more loosely, but gradually it has been narrowed to the signification above noted. See ANEMONE, CENOLATERA, CORAL, HYDRA, HYDROZOA, &c.; and POLYPUS, for the surgical use of the term.
Polyporus. See Amadou, and Dry Rot.

Polyporus, a genus of Ganoid fishes, of which only one species (P. bicirri) is known. It lives in the Nile and western rivers of tropical Africa. It may attain a length of 4 feet, and is esteemed as food. Very characteristic is a series of dorsal spines, with attached fillets, which extend almost the entire length of the back. Of its life very little is known. The only nearly allied living form is Coleochothys calabaricus from Old Calabar.

Polypus, in Surgery, is an ancient term employed to signify any sort of pedunculated tumour attached to the surface of a mucous membrane, to which it was supposed to adhere like a many-footed animal, as its name indicates. The most common seats of polypus are the nostrils and the uteri; but these tumours are also found in the rectum, the larynx, and the external auditory passage of the ear. The only satisfactory mode of treatment consists in their removal, which must be effected in various ways, according to their position, as by the forceps, écrasément, ligature, &c.

Polytechnique, or Polytechnic School (Gr. polye, 'many'; techné, 'art'), is an institute in which the technical sciences that rest in great part upon a mathematical basis, such as engineering, architecture, &c., are taught. The first school of the kind was established in Paris (1794) by the National Convention, under the name of School of Public Works. No students were admitted but those who intended to enter the public service, especially the corps of civil and military engineers and the artillery. The Polytechnic School, as it was called from 1795, has been repeatedly reorganised as the different political parties have succeeded to power. At the present time it is the Institute in which France trains her artillery and engineer officers, her naval engineers, her directors of roads and bridges, and of mines, her telegraph officers, in short, all her officials who require to know something of the higher branches of technical science. Germany too has her polytechnics. Those that came into being during the first half of the 19th century were in great part training-schools for the higher branches of the industrial arts; but since Zurich established (1855) a polytechnic modelled on the plan of the German universities, most of the German polytechnics have followed suit. Of these establishments, thus increased in scope (now called also Technische Hochschulen), Germany has nine or ten, and Austria-Hungary half a dozen; though Germany has also several other colleges which might fairly claim the name of Polytechnicum in the old sense. In the U.S. in America the oldest institutions of the kind are the Rensselaer Polytechnic Institute, at Troy, New York, and the Franklin Institute, at Philadelphia, both founded in 1824. There are now nearly a hundred technical schools in the United States, more than half of which were endowed with a national land-grant. See Technical Education; also Art; and Pinti, Histoire de l'Ecole Polytechnique (1886).

Polytheism. See Religion.

Polytrichum, a genus of Mosses (q.v.).

Polynya, or Brizozoa, a class of small animals which, with one exception, form colonies, and are almost always fixed. Most familiar are the sea-mats or horn-wrackes (Phustra), east-up pieces of which are sometimes found on the beach. On these will be seen the hundreds of separate chambers in which the minute individuals live. Each individual has a sac-like or cup-shaped body, traversed by a food-channel bent like a U, crowned around the mouth by a wreath of tentacles, controlled by a single nerve-centre. The cuticle which surrounds the body is usually horn-like, not so much asyndetic as gelatinous (Cellepora, Lepaila, &c.), and sometimes gelatinous (Alcyonidium, Lophosporium). The individuals of a colony are not always all alike; thus, some of them are occasionally modified into strange bird's-beak-like or whip-like structures. All Polynya multiply by budding, and thus the colonies increase. The individuals in the older parts of the colony usually degenerate or die. Fresh-water forms reproduce by peculiar winter-buds or statoblasts, which are liberated on the death of the parent, are floated away by currents, and after some months' quiescence develop into young buds. But all Polynya also reproduce sexually; the sexes may be separate or united; the larvae developed from the eggs are free-swimming. The Polynya used to be ranked with zoophytes (among the Hydrozoa), but the individual animals are much more complex and are independent of one another. Often they are called mulluscoids, because of apparent affinities with lamp-shells or Brachiopods, which used to be regarded as allied to molluscs. Most modern zoologists rank them as a distinct class, the Brachiozoa, in the great assemblage of 'worms' or 'Vermes.' Representative genera are Cristatella, Lophosporium, Pluma- tella—in fresh water; Flustra, Membraniporium, Alcyonidium, Cellepora—marine; Pedicellina and Loxosponia—two marine genera, simpler than the others, the latter non-colonial. R. hudsonia, a remarkable genus sometimes included in this class, shows at least hints of vertebrate affinities.

See Allman, British Fresh-water Polynya (Lond. 1886); Buck, Challenger Report, X. (1884); Hincks, British Marine Polynya (Lond. 1880); E. Ray Lankester, article 'Polynya' in Brit. Encyclopædia.

Pomacea, or Pomer, according to some botanists, a natural order of plants, but more generally regarded as a sub-order of Rosaceae (q.v.). The plants of this order are all trees or shrubs, abundant in Europe, and chiefly belong to the
temperate and colder regions of the northern hemisphere; they are rare in very warm climates, and are not found at all in the southern hemisphere. They have the botanical characters described in the article Rosaceae (q.v.), and in addition are distinguished by having the pericarp usually referred to as the teasel, the very fleshy and juicy, lined with a thin disc, its carpels adhering more or less to the sides of the calyx and to each other; the fruit a \textit{Pome} (q.v.), 1- to 5-lobed, in a few instances spuriously 10-lobed; the ovules in pairs, collateral. Many of the species are prized for the beauty and fragrance of their flowers, some produce valuable timber; but the order is chiefly remarkable as producing a number of the very finest fruits of temperate climates. See \textit{Apple}, \textit{Pear}, \textit{Quince}, \textit{Medlar}, \textit{Loquat}, \textit{Hawthorn}, \textit{Crataegus}, \textit{American Chokecherry}, \textit{Rowan Tree}, \textit{Service}.—There are about 200 known species.

\textbf{Pomade}, or \textit{Pomatium}, is a preparation of fine inodorous fat, such as lard or suet, used instead of liquid oil for the hair. It may be perfumed with various essences.

\textbf{Pombal}, Sebastião José de Carvalho e Melo, marquis of, the greatest of Portuguese statesmen, was born 18th May 1699, at the castle of Soure, near Coimbra. In 1739 he was appointed ambassador in London, and six years later was sent to Vienna in a similar capacity. Just before Joseph I. ascended the throne of Portugal (1750), Pombal was appointed secretary for foreign affairs. He was afterwards re-appointed to the crown a number of domains that had been unjustly alienated. When the great earthquake happened at Lisbon in 1755 Pombal displayed great calmness and fertile resources, so that next year the king made him prime minister. He crushed a revolt instigated by the great nobles and the Jesuits, and in 1756 abolished the latter from the kingdom. Then he abolished slavery in Portugal, set himself to establish good elementary schools, and published a new code of laws. Besides this, he effected the reorganisation of the army, the introduction of fresh colonists into the Portuguese settlements, the establishment of an East India Company, and another for Brazil. The tyranny of the Inquisition was broken. Agriculture, commerce, and the finances were all improved. In 1758 he had been made Count of Oeiras, and in 1759 became the marquis of Pombal. On the accession of Joseph's daughter, Maria I. (1777), who was under clerical influence, Pombal, who had himself been high-handed, if not despotic, especially towards the Church, was banished from court, while many of his institutions were abolished. He died at his castle of Pombal, 8th May 1782.

\textbf{Pome} (Lat. \textit{pomum}, 'apple'), the form of Fruit (q.v.), produced by the \textit{Pomaceae} (q.v.)—a fleshy, indehiscent, syncarpous fruit, with calyx attached.\n
\textbf{Pomegranate} (\textit{Punica granatum}), a fruit much cultivated in warm countries, and apparently a native of the warmer temperate parts of Asia, perhaps also of the north of Africa. It has been cultivated in Asia from the most ancient times, and is mentioned in the Old Testament. It has long been naturalised in the south of Europe. In a wild state the plant is a thorny bush, and in cultivation it is a low tree, with twiggy branches, flowers at the extremities of the branches, the calyx red, the natural astringent to the natural astringent. It is a medium-sized orange, having a thick leathery rind of a fine golden yellow, with a rosy tinge on the sunny side, not bursting when ripe; the cells filled with numerous seeds, each of which is surrounded with pulp, and separately enclosed in a thin membrane; the upper and lower series of carpels being differently attached. Thus the pomegranate appears to be formed of a great number of reddish berries packed together and compressed into irregular angular forms. The pulp is sweet, sometimes subacid, and of a pleasant delicate flavour, very cooling, and particularly grateful in warm climates. It is often used as a substitute for the preparation of cooling drinks. A kind of pomegranate without seeds is cultivated and much prized in India and Persia. Pomegranates have long been imported in small quantities into Britain from Portugal and the north of Africa, but have never become an article of general demand and commercial importance like oranges. There is an ornamental variety of the pomegranate with double flowers. The rind of the fruit is very astringent, and a decoction is used as a gargle in relaxed sore throat, and as a medicine in diarrhoea, dysentery, &c. Deriving its astringency from tannin, it is used to tan leather. The finest Moroccan leather is said to be tanned with it, and small quantities are imported into Britain from the north of Africa for the preparation of the finest kinds of leather, under the name of \textit{Pomacrate Bark}. The bark of the roots is used as an anthelmintic, and is often successfully administered in cases of tapeworm. It contains a peculiar principle called \textit{punigen}, having the appearance of an oleo-resin, an astringent taste, and affecting the parasite (\textit{Vermiculus Calci})—its value was known to the ancients, and it has long been in use in India. The pomegranate tree is occasionally cultivated in hothouses or greenhouses in Britain. It bears the winters of the latitude of London in the open air, and is very ornamental, but the fruit is worthless. In some parts of the south of Europe it is used as a hedge-plant. In northern Mexico it grows to great perfection, and in some of the southern states of the American Union; even as far north as New York it will, if protected in winter, bear fruit, and in some seasons ripen it.

\textbf{Pomerania} (Ger. \textit{Pommern}), a province of Prussia, bounded N. by the Baltic, E. by West Prussia, S. by Brandenburg, and W. by Mecklenburg. Area, 11,620 sq. m. It is one of the lowest and flattest regions in Germany, and has few hills of even moderate height, but many small lakes and ponds. The river Oder divides Hither Pomerania (next Mecklenburg) from Further Pomerania. The shores of the latter are lined with sand-dunes. The islands of Wollin and Usedom form the northern side of the Stettiner Haff (Lagoon); and farther to the north-west lies the island of Rugen. Pomerania is essentially an agricultural province, more than 55 per cent. of the total area being in tillage, whilst meadows cover another 19 per
cent, and forests nearly 29 per cent. Rye and potatoes are the principal products; in a secondary degree come wheat, barley, oats, flax, beet-root, tobacco, hops, and fruit. More than 55 per cent. of the soil is owned by the nobility, as in Mecklenburg (q.v.). Commerce flourishes in the coast towns, Stettin and Stralsund being the most important. Apart from shipbuilding, machine-working in the metals, manufacture of sugar, chemicals, bricks, &c., which are carried on principally in the coast towns, the only industries are paper, tobacco, glass, and wooden wares. The fisheries are valuable. Much poultry is reared, especially geese, in Farther Pomerania. The coast of the Gulf of Bothnia is the heart of its university; Stettin is the capital.
Pomerania sends fourteen members to the imperial Diet, and twenty-six to the Prussian Lower House.

POMEROY

Pomeroy, capital of Meigs county, Ohio, between the Ohio River and a range of precipitous hills, 133 miles by rail SE. of Columbus. The quarrying of coal and the manufacture of salt are the chief industries. It also contains foundries, a woolen-factory, &c. Pop. (1880) 5560; (1900) 4639.

POMFRRET

Pomfret, See Pontefract.

POMONIA, the Roman divinity of the fruit (pomum) of trees. She was beloved by several of the rustic deities, as Sylvanus, Panns, and Vertumnus. Propertius tells us that the last, after vainly trying to approach her under various forms, at last succeeded by assuming the figure of an old woman. In this guise he recounted to her the lamentable histories of women who had despised love, and, having touched her heart to pity, suddenly transformed himself into a blooming youth. Varro tells us that at Rome the worship of Pomona was under the care of a special priest, the Flamen Pomonalis. In works of art she was generally represented with fruits in her lap, or in a basket, with a garland of fruits in her hair, and a pruning-knife in her right hand.

POMONA, or MAINLAND. See ORKNEY.

POMPADOUR, JEANNE ANTOINETTE POISSON, Ma mère, who provided for her education the magnificent treasuries of Louis XV., was born in Paris, 29th December 1721. She was baptised as the child of François Poisson and his wife Madeleine de la Motte, but it was suspected that her father was Le Normant de Tourneham, a wealthy fermier général. For five years she grew up a woman of remarkable grace and beauty, devoted to music and painting, and charming every one by her vivacity and wit. But her mind was early depraved by her mother, who constantly dinned into her ears that she was 'un moreau de ro,' and habituated her to see in the rôle of royalty the idea of female domination. In 1741 she was married to her protector's nephew, Le Normant d'Étioles, and soon became a queen of fashion in the financial world of Paris. But neither this nor a devoted husband's love could satisfy her heart, and, as it was impossible to hope for an introduction at court, for two years she sought to attract the eye of the king by waylaying him when he went out hunting. At length in February 1745 she attained her object at a ball given by the city on the occasion of the dauphin's nuptials, and ever long she was installed at Versailles, and courted by the Duke of Marigny and Maréchal de Pompadour. Her husband, to whom she had already borne a daughter, was removed from Paris, but later had his place recouped with lucrative offices; her brother was afterwards made Marquis de Marigny. Ever long she assumed the entire control of public affairs, the king being nearly an inconstant frondeur who assisted at the spectacle of his reign without even taking an interest in it. For twenty years the mistress swayed the whole policy of the state, and lavished its treasures on the gratification of her artistic tastes, and in carrying out her ambitious schemes. She brought the traditional policy of France because Frederick the Great lampooned her, and the proud Maria Theresa addressed her in a letter under the royal style as Ma maîtresse. She filled all public offices with her nominees, corresponded with the generals in the field, and made her own revolutions. She was a favorite of the arts, and heaped her bounty upon poets and painters, yet did not eschew showers of lampoons—the famous Poissardes, for a suspected share in which a wit went to the Bastile. She loved china, fine buildings, books, and sumptuous bindings, and it is said she kept at her hands a fine edition of the Redingue of Corneille. Indeed, she was an artist in everything—'elle était des mères,' as Voltaire said truly when he heard of her death. The king remained faithful to her from habit rather than affection, and from the rôle of mistress she retreated into the rôle of senior, and retained her difficult position to the end, by relieving him of all business, by diverting him with private theatricals in her famous 'théâtre des petits cabinets,' where she acted charmingly, and at last even by contravening his infamous débâcles and providing him with mistresses too insignificant to be rivals. She herself said with the pathos of truth, 'ma vie est un combat;' and at last her nerves gave way under the strain, and after a languor of twenty days she died, 15th April 1764. She met the inevitable with that queenly dignity that made everything she said the more muffled on the wings of a playful salut—'Stay, Monsieur Curé,' she said to the priest who was leaving her room, 'wait a little; we shall go out together.' Madame de Pompadour was the last mistress of the king worthy of the name; the descent from her is interrupted by a blank. The leniency of the North-agencies of Durbary was profound. She was 'froide comme une mèreuse,' says Madame du Hausset, her femme-de-chambre, in her silly but interesting memoirs, and there can be no doubt that throughout her lifetime ambition was the one passion of her heart. She secured this for herself and her son. When the sooner had she closed her eyes than she was forgotten.

The Mémoires (Liége, 1700) attributed to her are of no value. See the studies by Capefigue (1858) and Campardoun (1867): E. and J. de Goncourt, Les Mémoires de
Pompeii, a seaport at the mouth of the Sarnus, on the Neapolitan Riviera, founded about 600 B.C. by the Oscans, and, after them, occupied by the Tyrrheno-Pelagians, and by the Samnites, till these, about 80 B.C., were dispossessed by the Romans. From that time down to its destruction, 79 A.D., it became (with Herculaneum) a sort of Roman Pompeii, frequented by the aristocracy, if not by Caligula and Nero, in whose honour it erected triumphal arches. Fed from the capital with every luxury and distinction, it included temples in which the inhabitants were encouraged to make costly sacrifices with all their adjuncts of festivity and banqueting; indeed, its public monuments, out of all proportion to its size, were in number and magnificence such as we can now but dimly estimate. On February 5, 63 A.D., by an earthquake in the vicinity, these buildings were all but levelled with the ground, and some years elapsed ere the fugitive citizens recovered confidence enough to reoccupy and rebuild what was once Pompeii. Reconstruction was carried out with a waste and disregard of architectural law contrasting strongly with the earlier work—the Forum especially exhibiting the inferiority of its Roman to its Greek builders. Tawdri ness replaced simplicity of decoration—the columns, capitals, cornices, being ornamented with reliefs in stucco picked out with parti-coloured designs, while private houses, fantastically restored and adorned, infringed every artistic or aesthetic canon to favour the grotesque style of the Decadence. Reuniformised as it was for the worse, the city, however, retained a good deal of Greek character and colouring, and had relapsed into more than its former gaiety and licentiousness, when on the 23d August (or, more probably, on the 23d November) 79, with a return of the shocks of earthquake, Vesuvius was seen to throw up a column of black smoke expanding like some umbrella-pine of the neighbourhood, till it assumed the proportions of a great swarthy cloud, dense with ashes, pumice, and red-hot stones, settling down on the doomed cities with a force increased by the rain-torrents that intermittently fell. Amid the impenetrable gloom that veiled land and sea, the panic of the citizens was aggravated by repeated shocks of earthquake, and for three days the flight continued till Pompeii was abandoned by all who could effect their escape. By the fourth day the sun had partially reappeared, as if shining through a fog, and the more courageous of the citizens began to return for such of their property as they could disinter. Much was doubtless recovered or possibly stolen; but the desolation and distress were such that the reigning emperor Titus organised relief on an imperial scale, and even undertook the clearing and rebuilding of the city. This attempt was soon abandoned, and Pompeii remained a heap of hardened mud and ashes, gradually overgrown with grass—the wall of the great theatre and the outline of the amphitheatre alone marking its site—till 1592, when the architect Fontana, in cutting an aqueduct, came on some ancient buildings. These were long believed to mark the old Stabiae; and only in 1748, under the Bourbon Charles III., were they recognised as part of Pompeii. Unsystematic, unscientific excavations proceeded fitfully till 1860, when the Italian kingdom took in hand the unearthing of the city. This was carried out with admirable ingenuity, care, and success—all treasure-trove being vigilantly preserved, and an archaeological record kept by the official excavators Fiorelli and Ruggiero, till now Pompeii possesses a distinction unknown to it in the zenith of its imperial favour, and attracts the pilgrim from every clime for the object-lessons it is unique in affording as to the public and private life of antiquity.

We cannot give more than the merest indication of the outline and distribution of Pompeii as now exposed. In form an irregular ellipse, extending from east to west, in circumference about 2843 yards, it had eight gates to which archaeology has given names mostly conjectural. It had outgrown its walls, however, particularly towards the sea, and developed considerable suburbs. Its most important part—not quite one-half, including Forum, adjacent temples and public buildings, two theatres with colonnades, amphitheatre, and many private houses—has already been exhumed, and five main streets made out and (provisionally) named. It has been divided, by official arrangement, into nine regiones (quarters), seven of them wholly or partially excavated, and each is subdivided into insulae (blocks), bounded by four streets and provided each with a number, as are also the streets of each quarter. A trottoir borders the streets, which are straight and narrow—the broader 24 feet wide, the narrower 14 feet only—and admirably paved with polygonal blocks of lava. High stepping-stones, placed mostly at the corners, lead across from one trottoir to another, and these retain the impressions of horses' hoofs, while in the causeway between the wagons have left deep ruts. The street corners are provided with fountains, ornamented usually with the head of a god or a mask. Notices painted in red letters, and referring to municipal elections for which some particular candidate is recommended,
occur frequently on the street walls, while trade-signs are few and far between. An occasional 'phallus,' to avert the evil eye, projects from over a doorway, and, much more common, one or two large stone blocks, especially at the corners. These were two-storied, sometimes three-storied houses are numerous, though the upper floors, built of wood, have been consumed by the eruption. Shops usually occupied the ground floors of dwelling-houses, on their street aspect, let out to merchants or dealers as at the present day, but not connected with the back part of the house. They could be separated from the street by large wooden doors, while inside they had tables covered with marble, in which earthen vessels for wine or oil were inserted. The shopkeeper had sometimes a second room at the back of his shop, with a floor over another part of the town. Retail traffic must have been considerable at Pompeii, to judge from the number of those shops along the streets, which, when not so flanked, presented bare walls, occasionally enlivened with a painting. Only a person of some importance, or with an idea of trade, like the Pompeians, with whom the absence of glass, the fewness of the openings in the street aspect of the house-wall, and the protection of these with iron gratings are among the points noted by the most casual visitor. Models of the interior of an entire house in its entire length are given in the fuller guide-books to Pompeii—the feature that most strikes the northerner being the smallness of the rooms, particularly the dormitories—quite intelligible, however, when he realises that the Pompeians led an open-air life, and performed their toilets at the bath, public or private. As rebuilt after 63, Pompeii shows little marble, the columns being of tufa or brick cemented by mortar. A coating of stucco was laid over wall or column, and presented an ample field for ornamental painting. This must have given to Pompeii its bright, gay appearance, with the blues, greens, yellows, on column and capital, on wall and partition, harmonise so well with the glowing sunlight of the south. On the centre of the interior walls is generally seen a painting unconnected with the others—often of a nymph, or a genius, when not decorated erotic in theme, typifying faithfully a voluptuous sensuous life of this pleasure-haunt of paganism.

Thanks to photographs, to the excellent plans in the best guide-books, and to models, the reader, as the next best thing to a personal visit, can make a tour of the excavated portion of Pompeii, and, from the minute and trustworthy descriptions of the temples, basilicas, public buildings, and private houses, form a vivid realisation of the city in its most frequented and animated quarters. Here the phenomena which struck such a man as E. Neville Rolfe's 'Pompeii, Past and Present,' illustrated by photographs of the ruins as they are, with sketches of their original elevations (Lon. 1884). The student who wishes to enter fully into the whole subject should read Maizis, Les Ruines de Pompei (4 vols. Par. 1812-23); Nissen, Pompeian. Studien zur Städtekunde des Alterthums (Leip. 1877); Funck, Geschichte der dekorativen Wandmalerei (Hamb. 1882); and Th. Overbeck's Pompei (Leip. 1884); K. Lange, Haus und Hall (Leip. 1885); while Professor Fiorelli's great work, Gli Scavi di Pompei del 1861 al 1872, is a mine of information, supplied at first hand by the official excavator, and bearing witness to the immense ingenuity of the method by which, pouring in liquid plaster of Paris into the hollows occupied by the skeletons of the victims of the eruption, and allowing it to harden, he obtained a 'perfect cast, consisting of the bones of the deceased Roman citizen, clad no longer in flesh, but in plaster of Paris.

Pompeii, the rival of Caesar, was born in 106 B.C., and at seventeen fought along with his father in the Social or Italian war on the side of Sulla against the faction of Marius and Cinna. When Sulla returned from Greece to Italy to oppose Marius (84) Pompey hastened into Picenum, and there raised an army of three legions, with which he drove the soldiers of Marius out of the district, and then joined Sulla. For his prudence, valour, and good fortune throughout the civil wars he was awarded the Marian faction in Africa and Sicily. On his triumphant return to Rome he was honoured with the name of Magnus, or the Great. His triumph was an unprecedented distinction for one who had not yet held any public office and was merely an owner of a few estates, some 300 acres, outside Rome. With the followers of Lepidus, whom he drove out of Italy, and the extinction of the Marian party in Spain under the brave Sertorius (75-71), Pompey suffered some severe defeats from Sertorius, and, indeed, put an end to the war only after his assassination, but his successor, his adopted son, the agent of his political establishment, fell in with the remnant of the army of Spartacus, and thus closed the Servile war. He was now the idol of the people, and, though legally ineligible for the consulship, was elected for the year 76, the senate relieving him of his disabilities rather than provoke him to extremities. Hitherto Pompey had belonged to the aristocratic party, but of late years he had been looked upon with suspicion by some of the leading men, and he now publicly exposed the people's cause. He carried a law restoring the tribunial power to the people; and sided largely in introducing the Lex Aurelia, by which the judicatores should for the future be taken from the senate, the equites, and the tribuni curiae, instead of from the senate alone. In 67-66 Pompey cleared the Mediterranean of the pirates who infested it; and during the next four years (65-62) conquered Mithridates, king of Pontus, Tigranes, king of Armenia, and Antiochus, king of Syria. At the same time he subdued the Jews and captured Jerusalem. On his return to Italy he disbanded his army, and entered Rome in triumph for the third time in 61. But now his star began to wane, as before. He had the two Julia died in 54, and thus father-in-law and son-in-law were
Pompey's Pillar

Poniatowski

sundered by a yet wider gulf, which no bridge could span. Pompey now returned to the aristocratic party, whose great desire was to check Caesar's views, and strip him of his command. Caesar was ordered to lay down his office and retire to Italy, which he consented to do, provided Pompey, who had an army near Rome, would do the same. The senate insisted on an unconditional resignation, and ordered him to disband his army by a certain day, otherwise he would be declared a public enemy. To this resolution of the triune nobility, Pompey objected; they therefore left the city and cast themselves on Caesar for protection. It was on this memorable occasion that he crossed the Rubicon, and thus defied the senate and its armies, which were under Pompey's command. The events of the civil war which followed have all been recorded in the life of Caesar. It remains only to mention that, after being finally defeated at Pharsalia in 48, Pompey escaped to Egypt, where, by order of the king's ministers, he was treacherously murdered by one of his former centurions as he was landing from his boat. His head was cut off, and afterwards presented to Caesar on his arrival in Egypt. But the magnificent order of execution of the murderer of Pompey. The body lay on the beach for some time, until it was buried by a freedman, Philorus, who had accompanied his master to the shore.

Pompey's younger son, Sextus, by his third wife, endeavoured after his father's death to prolong the struggle with Caesar. He secured a large fleet, manned largely by slaves and political exiles, and occupying Sicily, ravaged the coasts of Italy. But in 36 B.C. he was defeated at sea by Agrippa, and the next year was slain at Mitylene.

Pompey's Pillar, a celebrated column standing on an eminence about 1800 feet south of the walls of Alexandria. It is a red granite monolith, of the Corinthian order, 73 feet high, or with pediment, 93 feet 9 inches; circumference, 23 feet 8 inches. On the summit is a circular depression for the base of a statue. The Greek inscription on the base shows it to have been erected by Publius, prefect of Egypt, in honor of the Emperor Diocletian, supposedly to reerect the famous Pillar of Alexandria. 29320. The popular name was erroneously applied by old travellers.

Ponanu, a seaport town of British India, in the district of Malabar, 30 miles S. of Calicut. Pop. 12,241, mostly Mohammedans.

Ponapé. See Caroline Islands.

Ponce, a seaport of Porto Rico, the second in importance, about 45 miles SW. of San Juan. The harbor is spacious. Pop. (1899, 52,296; 1909, 86,546) produces sugar, cocoa, tobacco, oranges, &c.

Ponce de Leon, Fray Luis, a celebrated Spanish poet, was born in 1527, probably at Granada. He studied at Salamanca, entered the order of St. Augustine, and became professor of Theology there in 1561. His translation and interpretation of the Song of Solomon, later his De los Nombres de Christo (1583-85) and La Perfecta Cassada (1583), full of imagery, eloquence, and enthusiasm, and both in prose. Shortly before his death, which occurred in August 1581, he was taken apprehended of his order. His poetical remains were first published by Quevedo at Madrid in 1631, under the title Obras Propias y Traducciones. The latter consist of translations from Virgil's Eclogues and the Georgics, the Odes of Horace, and the Psalms. His original poems are few, but they are among the masterpieces of Spanish lyrical poetry.

There are German monographs by Wilkens (1866) and Beneck (1873); also a Spanish Life by Tejeda (1863).

Ponce de Leon, Juan, the discoverer of Florida, was born at Sanlúcar de Barrameda, in Spain, in 1496, was a court page, served against the Moors, and in 1562 sailed with Ovando to Hispaniola, and became governor of the eastern part of the island. In 1510 he obtained the government of Porto Rico, and had conquered the whole island by 1512, when he was deprived of his post. He then, broken in health, set out on a quest for the fountain of perpetual youth, and on 27th March 1512 found Florida, landing a little to the north of where St. Augustine now stands. He secured the appointment of adelantado of the country, and, after staying on his way back to drive the Caribs out of Porto Rico, he returned in 1521 to conquer his new subjects; in this, however, he failed, and lost nearly all his followers. He retired to Cuba, and died there in July from the wound of a poisoned arrow. His remains and a monument are in San Juan de Puerto Rico.

Poncho, an important article of male attire in Chili, the Argentine Republic, and some other parts of South America (see Gauchos). It consists of a piece of woollen or alpaca cloth, 5 to 7 feet long, 3 to 4 feet broad, having in the middle a matting through which light weather passes his person so that the poncho rests upon the shoulders and hangs down before and behind.

Pond. See Water-supply.

Pond, John, astronomer-royal, was born in London in 1767, studied at Cambridge, and succeeded Maskelyne as astronomer-royal in 1811. His name is identified with numerous improvements in the methods and instruments of observation; he translated Laplace's Système, and published a star catalogue and many valuable papers. He died 7th September 1836.

Pondicherry, the chief of the French settlements in India, situated on the Coromandel Coast, 33 miles S. by W. of Madras City, is divided into two parts by a canal. White (European) town being next the sea. It has handsome streets, a government house, a college, a lighthouse, and a cotton-mill employing 1500 hands, besides native dyeing establishments. Pop. 41,856. It exports chiefly oil-seeds. The French colony of Pondicherry has an area of 115 sq. m. and a pop. of 140,945. The governor of Pondicherry is governor-general of the French possessions in India. The French first settled here in 1674. The Dutch took the town in 1695, but restored it to the French in 1697. In 1748 Admiral Boscawen besieged Pondicherry for two months, but was compelled to raise the siege. Eyre Coote, however, took it in 1761, yet it was restored to the French in 1763 with reduced territory. It was once more taken by the English by Sir Joseph Banister in 1772, and once more given back in 1785. In 1773 the English again repossessed themselves of it, but it was a third time restored to the French in 1816.

Pondoland, a district of Kaffirland, on the Natal frontier, South Africa, 65 miles long by 30 wide, was annexed to Cape Colony in 1884 and 1887, except Port Natal (Zululand), which (with a pop. of 200,000) was annexed in 1884.

Pond-weed. See Aquatic Plants.

Pongwe. See Pungwe.

Poniatowski, a princely family of Poland.Stanislas (1677-1762) joined Charles XII. of Sweden in supporting Stanislas Leszczynski, and was the chief instrument in saving the Swedish king at Pultowa. He held his administrative
of Capec, with 5172 inhabitants. It has an old cathedral and a castle. It was long attached to the State of the Church. Napoleon I. gave the title of Prince of Pontecorvo to Marshal Bernadotte, afterwards king of Sweden.

**Ponta Delgada**, the largest town of the Azores (q.v.), on the south coast of São Miguel. Pop. 17,940.

**Pontefract**, or POMFRET, a pleasant market-town in the West Riding of Yorkshire, on an influx of the Calder to the Aire, 13 miles SE. of Leeds, 8 E. by N. of Wakefield, and 14 NNW. of Doncaster. It stands on the line of a Roman road, but seems to have arisen round its Norman castle, which, founded about 1076 by Gilbert de Lacy, was the scene of the execution or murder of the Earl of Lancaster (1292), Richard II. (1409), and Earl Rivers (1453), was taken in the Pilgrimage of Grace (1536), and during the Great Rebellion sustained four sieges, being finally dismantled in 1649, after its capture by Lambert. There are two old churches, a town-hall (rebuilt 1766), a good grammar-school of Edward VI. (1549), and large market-gardens and nurseries, the growing of gingerloes for the lozenges called ‘Pontefract cakes’ being a specialty as old as about 1652. At Ackworth, 3 miles south, is a large Quaker school (1778). Pontefract, called ‘the Gulf in the footpath’ was first time it has received its present name between 1086 and 1135. Why is uncertain, but there is a very full discussion of this difficult question in Notes and Queries for 1886–87. The borough, which was chartered by Richard III., lost one of its two members in 1721. The parliamentary borough (1831) 11,515; (1881) 14,767; (1891) 16,407, of whom 9702 were within the municipal boundary. See works by Paulden (1702), Tetzl (1769), and Boothroyd (1807).

**Pontarlier**, a French town (dept. Doubs), 35 miles SE. of Besançon, on the main Jura route from Switzerland to France. Pop. 6759.

**Pontchaillou**, in the department of Loire, France. The drainage of New Orleans (q.v.) is carried into the lake through canals.

**Pontecorvo**, a city of the Italian province of Caserta, on the river Garigliano, 37 miles NW. of Capua, and 5172 inhabitants. It has an old cathedral and a castle. It was long attached to the State of the Church. Napoleon I. gave the title of Prince of Ponte corvo to Marshal Bernadotte, afterwards king of Sweden.

**Ponta Delgada**, the largest town of the Azores (q.v.), on the south coast of São Miguel. Pop. 17,940.
Pontificial, one of the service-books of the Church of Rome, in which are contained the several services, whether in the administration of sacraments or the performance of public worship, in which the bishop or a priest delegated by the bishop officiates. There were many such collections for the various national churches; but that which is now in universal use throughout the Western Church is the Pontificale Romana, first issued in 1435, revised under Clement VIII. in 1596, and repeatedly republished since that time. The Pontificale contains the services for ordinations, for religious professions and receptions of monks and nuns, consecrations, benefications, and similar functions. It is handed over to the incumbent of a church by a bishop of those sacraments which are ordinarily administered by priests. Besides the prayers to be recited, the Pontificale also lays down the ceremonial to be observed.

Pontifical, a village of the French department of Yonne, 18 miles SE. of Auxerre, with a famous Cistercian monastery, dating from the 12th century. Three English archbishops retired hither, Becket in 1164, Beaulieu Langley in 1195, and St. Edmund of Canterbury in 1240, the last being buried here. The monastery was devastated by the Huguenots in 1657, and finally destroyed at the Revolution; but the church (mainly 1150-70) is the most perfect Cistercian church in existence. To the shrine of St. Edmund (18th century) in this church came in 1874 a pilgrimage of English Roman Catholics.

Pontine Marshes (Lat. Pontinæa Paludes), a low-lying district, the southern part of the Campaign of Rome, extending south-east from Velletri to the sea, at Terracina, 20 miles inland. The district is separated from the sea by sandunes, and is traversed by the Appian Way. Herds of cattle, horses, and buffaloes feed on its pastures. Many attempts have been made to drain these marshes, from that of Appius Claudius (312 B.C.) to the proposals of Captain von Donat (1857), amongst the promoters of these drainage schemes being Augustus, Trajan, and the popes Boniface VIII., Martin V., Sixtus V., and Pius VI.

Pontoon (Fr. ponton; Lat. pons, 'a bridge'), the name given to buoyant vessels used in military operations for supporting a temporary bridge. Marlborough used clumsy wooden pontoons. Napoleon and Wellington had them lighter of tin and copper. They were flat-bottomed, rectangular boats, open at the top. Tin cylinders were then used for some time, but light open boats are now carried by the pontoon troops of the Royal Engineers for large bridges capable of carrying artillery, and Berthon's collapsible boats are sometimes used for small infantry bridges. See BRIDGE, Vol. II. p. 447; and for pontoons in connection with floating-docks, see Dock, Vol. IV. p. 32.

Pontoppidan, Erik, Danish writer, born at Aarhus on 24th August 1688, was appointed professor of Theology at Copenhagen in 1738 and bishop of Bergen in Norway in 1747; there he died on 20th December 1764. His writings are principally historical and theological; amongst them must be mentioned Annales Ecclesiæ Danicae (1741-52), and his Historical Dictionary of the Danish Language, and still of use as a book of reference; Det Danske Atlas (1781), an unfinished historical and topographical account of Denmark; Glossæster Norwegicæ (1749), a work on Norwegian dialect words; Explanation to Anther's Catechism, used as a text-book in Town of the present day; Moreres Danica (2 vols. 1739-41), a collection of Danish inscriptions; and Norges Naturtids Historie (2 vols. 1752-54; Eng. trans. Natural History of Norway, 1763), containing accounts of the Kraken, the sea-serpent, and other marvels.

Pontresina, a tourist centre in the Swiss canton of Grisons, stands in the Upper Engadine, on the road connecting with the Bernina Pass, and is much frequented by Alpine climbers. Pop. 383.

Pontus, the name given by the ancient Greeks to a country in the north-east of Asia Minor, bordering on the Pontus Euxinus (whence its name), and extending from the Black Sea west to the frontiers of Colchis and Armenia in the east. Its southern limits were the ranges of Anti-Taurus and Paryades, so that it corresponded pretty nearly to the modern pashalikks of Trebizond and Sivas. The name seems to have come into use after the time of Alexander the Great, and it is obvious that Pontus was governed by a satrap for the empire of Persia. One of these satraps, Ariobarzanes, early in the 4th century B.C., laid the foundations of an independent sovereignty. He
POOLE

A game played on a billiard-table. Any number may play. Each is provided with a coloured ball, taken at random from a pool-basket. The first in order (white) is spotted on the billiard-table. The next (red) plays from hand on the white. Red is called white's player. The next (yellow) is red's player, and so on, in the order indicated by the marking-board. The owner of each ball has three lives. If the player holes the ball he plays on, or any other ball, after having hit first his own ball he plays on, the owner of the ball hole loses a life, and has to pay to the player a sum previously agreed on. The player plays again, from where he stopped, on the nearest ball; and so on until he fails, when the next player goes on, or until there are no other balls on the table, when the striker's ball is spotted. After the stroke from hand the player, unless spotted, always plays from where he is on the table; when he is holed he plays his next stroke from hand. If the player holes his own ball or gives a miss he loses a life, and plays his next stroke from hand. When the owner of a ball has lost all his lives he is declared, and plays no more that pool. The first dead may star—i.e., may come in again with the smallest number of lives on the board. In the end one or two of the players, who have not lost all their lives, remain in. They continue to play until they have an equal number of lives, when they divide the pool (a sum contributed by each player, generally equal to the value of three lives, the star paying an extra pool). If one of the two who remain in has more lives than the other, and kills his adversary, he takes the whole pool. The above describes briefly what is called following pool. The principal varieties are selling pool, where the player may play on any ball he likes; and black pool, where an extra ball is spotted on the centre spot and has to be played on under certain conditions, about which there are no fixed rules. When the black is holed black pool each of those in has to pay a life; if missed or run off in the player has to pay a life all round. There is no pool, and no one has any specified number of lives, the game continuing for a given time (generally half an hour). Snooker pool is played in the same way as moorder (see PYRAMIDS), the players following each other as at pool, and the order of play being determined as at pool.

POOLE

A sea-port in Dorsetshire, 5 miles W. of Bournemouth and 30 E. of Dorchester. It stands on the north side of Poole Harbour (7 by 43 miles), an irregular inlet, formed by the projection of the 'Isle' of Purbeck, almost dry at low-water, and having a day. On Brownsea or Brownsea Island, just within the narrow entrance to the harbour, is a castle dating from the time of Henry VIII. Poole itself has an old town-hall (1572), a guildhall (1761), a town-house (1822), considerable shipping, some yacht-building, and a large trade in pottery's for the clay. The men of Poole are great fighters in days of old by land and sea, as buccaneers, smugglers, and Cromwellian soldiers. There was 'Arripay,' or Harry Page, who about

1400 kept the seas against France and Spain; and there was William Thompson, who, with a man and a boy, captured a French privateer in 1683. Till 1867 the borough returned two members, and the town till 1851 (1831) 923; (1811) 12,310; (1891) 15,405. See works by Hutchins (1789), Sydenham (1839), and Brannon (3d ed. 1859).

Poore, John, playwright, born in 1792, died in February 1879 at Kentish Town, London, wrote the immortal Paul Pry, first produced at the Haymarket in 1821, and several other pieces and comedies, such as Turning the Tables, Dead as a Post, Twouid Puzzle a Conjuror, The Wife's Stratagem. Besides these theatrical pieces he wrote also the satirical Little Pilottington (1839), The Comic Sketch Book (1839), Comic Maccaroni (1843), Comic Almanac (1845), and other books of a light, humorous kind.

Poole (or Pool; Latinised Polus), Matthew, divine, was born at York about 1624, educated at Emmanuel College, Cambridge, and held from 1648 till the passing of the Act of Uniformity (1662) the rectorcy of St Michael le Querne in London. He died in London and was buried there in 1679. His principal work was his Synopsis Criticorum Biblicorum (5 vols. fol. 1669-76), in which the opinions of 150 biblical critics were summarised. In his English Annotations on the Holy Bible he had only reached Isaiah when he stopped, but his work was completed by his friend (2 vols. fol. 1683). Effective contributions to the funerary controversy were The Nullity of the Romish Faith (1666) and Dialogues between a Popish Priest and an English Protestant (1667).

Poore, William Frederick, the compiler of the Index to the Salem at Salem, Massachusetts, 24th December 1821, and graduated at Yale in 1849. While there he was librarian of a literary society, and prepared an index (pp. 154) of periodical literature, enlarged in the 2d and 3d editions (pp. 1469), the latter published in 1882, with the assistance of the American and British Library Associations. A supplement (pp. 496), by Poole and W. J. Fletcher, of Amherst, was issued in 1888. A similar one was promised for every five years; further issues are in 1893 and (after Poole's death) 1897.

Poole was librarian of the Boston Athenaeum, and the library of the New Haven Library 1869-73, the Chicago Public Library 1873-87, and the Newberry Library, Chicago, from 1887 until his death at Evanston, Ill., 1st March 1894.

Poonah, or Punna, a town of British India, 119 miles by rail SE. of Bombay, is the military capital of the Deccan and the seat of the government of the presidency during the last half of the year. The city is embrowned in gardens, but its streets are mostly narrow or crooked, and the houses poor. The ruins of the pasha's palace, burned in 1827, still remain. Under the pasha the city was the capital of the Mahratta princes and power; it was occupied and annexed by the British in 1818. Here have been built the Deccan College and the College of Science, the latter for training civil engineers, a normal school and normal college, a high school, and other educational establishments.

The Europeans live chiefly at the cantonments, north-west of the city. The natives manufacture cottons and silks, gold and silver jewellery, ivory and grass ornaments, and clay figures. Pop. (1851) 73,203; (1872) 90,430; (1881) 119,062, of which must be added 20,000 in cantonment; (1891) 160,460. The visitations of the sanitary authorities to native houses during the plague here in 1897 led to riots and murderous assaults.

Poonowood is the timber of the Pooon trees of India and Burma (Calophyllum inophyllum and C. magnifolium). It is very commonly used in the East Indies, particularly in shipbuilding, for planks and spars. See TACAMAHACA.

Poor Clares. See Clare (St).

Poor-laws. Charity, like Christianity, had its origin, or earliest development, in the East. Among the primitive nations of the world almsgiving was inculcated as a religious observance, and is prescribed as such in their sacred records. Among the European nations of antiquity we find a provision for the poor adopted as a matter of state policy. In early times Athens could boast of having no citizen in want; nor did any disgrace the nation by begging. But war at length brought poverty and the paupers, and the state decreed the maintenance of those who were militated in battle, and, at a later period, of the children of those who fell. Pintarch mentions Pisistratus as the originator of the first decree, though others derive it from Solon. By the latter decree those who had armies and the distribution of grain to their soldiers up to their eighteenth year, and then sent them into the world with a new suit of armour. The bounty given to the disabled is mentioned by Lysias, Harpocration, Aristotle, Isocrates, and others; it is variously stated at one, two, and three obols, and it is said that the expenses of the money advanced to them when they had raised themselves to better circumstances. But it must be remembered that these so-called democratic states were in reality slave-holding aristocracies.

Among the Romans the Agrarian Law of Licinius Stoilo (367 B.C.) is the first in which the system is elaborated. It limited the extent of property in public land to be held by each citizen, and directed that all such land above the allotted portion should be taken away from the holders, and given to the poor. The distribution of grain at reduced prices, which at length became gratuitous, was introduced by Caius Gracchus, and lasted till the fall of the Roman empire. Augustus in vain tried to suppress it. In his time 200,000 citizens were thus relieved.

The provision was not administered as a charity, but the latter term is in great favour with the Roman people, because it furnished them with an abundant subsistence without labour; other Roman writers describe its results as disastrous both to agriculture and to manners, creating a nation of mendicants, and causing the land to fall out of cultivation.

In the middle ages the great body of the labouring classes were in a state of serfdom, and looked to their feudal lords for maintenance. The obligation to provide for their slaves, or serfs, seems to have been fully recognised, so that many, encountering in a state of freemen the miseries of want, went back to bondage as a refuge from destitution. The vassals in Saxon England were attached to the soil, and received from their lord a portion of land for the support of themselves and their families. But the Church of Rome constituted herself the great receiver and dispenser of alms. The rich monasteries and abbeys distributed doles to the poor, as is still done at the masques under the Mohammedan system.

In most states of continental Europe the church remains to a larger or smaller extent the public almoner, the state only stepping in to supplement the offerings of the church and voluntary charity when they become deficient. The disincarnation from the church is hardly anywhere so complete as in England. The laws of different countries vary as to the degree of want enabling a pauper to
relief, the extent to which the right to relief is matter of positive right, the conditions which give rise to the claim of relief, the incidents of taxation, and the obligation of the relieving authority.

It is only in Prussia, Denmark, and Sweden that there is any legislative declaration of the right to relief; and only in Britain and Denmark is any special tax imposed for this purpose. On the continent of Europe, generally speaking, the administration of relief falls on the parishes or commune, but the responsibility of supervision undertaken by central departments varies greatly; no workhouse test is applied; and the statistics are not reliable. In northern Europe there has been a more decisive separation of poor-law functions from the rest of social duties. In Denmark the old poor department in 1867–68 to one of elective unions in rural districts, the burgomaster and town-council becoming the poor-law authority in each considerable town. The overseers are amateurs, and medical aid is universal. In Sweden the law formerly rested on the Church Ordinance of 1571, but the statutes of 1871 (translated by Nassaum Jocelyn and criticized by Lamasses) have made great changes, the relief of the able-bodied being prohibited, a direct liability being placed on the larger employers of labour, and a system of poll-taxation introduced. In Norway the location of the district (consists) the poor-law of 1845 was altered in 1863 in the direction of greater strictness, relief being restricted in theory to orphans and persons of unsound mind, and a maximum assessment fixed. Among other sources of income there is an excise duty on beer. In north Germany the old law of 1577 was gradually enlarged—e.g. by the Convention of Gotha and Agreement of Eisenach, dealing with the matter of settlement. In 1867 a law of free settlement was passed, and in 1870 by a general law the period of two years was fixed for pauper domicile. In Prussia this is further developed by a statute of 1871, which connects the Bezirksregierung, or local government, with the parish poor-law authority. The peculiar system of Leipzig (founded on that of Hamburg) is carried on by an Armensdirektorium, amateurs of good social position, who make inquiries and attempt to settle cases by means of a Fragebogen, or question-paper.

In the Hanse towns there was introduced in 1788 a system of voluntary contributions aided by fixed subsidies from the government. This at length resulted in government supply all deficiencies, with a yearly expenditure of 1 per cent. of the cost of the general poor relief. At the treaty of Versailles (1870) Bavaria preferred to remain under her own law of 1816, amended in 1829. In Belgium, known as the classic land of pauperism, there is no poor-rate, but large parochial endowments exist. As in France, there are hospices civiles for indoor relief, and bureaux de bienfaisance for outdoor relief. The law may be enforced on communes by the Deputation Permanente of each province. One-third of the Belgian proletariat are inscribed on the poor-lists (see Laurent, Le Pauvrehomme et les Associations de Prévoyance). In Russia the poor-law has been modified by the communal system of land-tenure and the large amount of unoccupied crown-land. Down to 1864 the landlord was bound to feed the serf, and there were also provincial charitable societies, which supplied regularly 10 per cent. of the poor-law, however, was in that year handed over to the new Zemstvos, or local representative assemblies, who tax real property for this purpose. There is in St Petersburg a Grand Philanthropic Society with numerous branches; and many of the poor-law charity was transferred in the time of Catherine II. with the property of the monasteries. In Italy there is a remarkable absence of compulsory provision, except for lunatics and foundlings, but the charitable foundations amount to more than thirty millions sterling. The laws of 1870 are the last attempt to make a corporation to submit to the supervision of the representative provincial assembly. In Rome the Commissione di Carità has many peculiar features. Holland has no law of settlement.

In Austria each commune is charged with the relief of its poor. All who have legal domicile, or who, being unable to prove their domicile, are resident in the commune, are entitled to relief out of the general assessment. There is no special rate, and the administration is strictly municipal. In many provinces private charity is associated with public; the commune and overseers allow a few chosen inhabitants, who are called 'Fathers of the Poor,' and an officer accountable to the commune. This system is called the 'Pfarrarmen Institute,' and their funds are principally derived from private sources; but they receive a third part of the property of ecclesiastics who die intestate, and certain fines, &c. The 'enlarger system,' or boarding-out system, obtains to a large extent as regards both old and young paupers.

In France the law of 1798 distinctly negatived the right to relief. The present system rests mainly on the ordinance of 1807. The poor-law of 1872. The law of 1867 secured the intervention of the prefect. The relief of the poor is not compulsory, in as far as its distributors may, after making inquiry, refuse relief, except in the case of foundlings and lunatics. The minister of the Interior has a general superintendence of the machinery of relief, as well as the immediate administration of many large hospitals and refuges. The departmental funds are called upon for compulsory relief, but the commune is the main source of public assistance. It encourages and stimulates voluntary charities, and receives gifts for the benefit of the poor. The administration of the hospitals, and of the relief given at the homes of the poor (secours à domicile) is under the separate management of unaided commissions, who co-operate with the communal authorities. The dépôt de mendicité is a large establishment for registering cases of vagrancy, and like the criche is departmental. The work of the public dispensary is largely done by societies of charity at a small salary and with unsatisfactory results, as at Boulogne.

In Holland pauper colonies have been supported by the government. Vagrants, after a short imprisonment, are sent to one of these, under a rigorous system of discipline. Panpers of good character are sent to maintain themselves and their families by agricultural labour in free colonies. The working of the system is pronounced costly and unsatisfactory. A description of the chief voluntary experiments in dealing with the poor in Europe will be found in The Charities of Europe, by John de Liefde (1863).

The annals of the poor in England are neither short nor simple. Severe enactments for the repression of vagabondage and mendicity date from a very early period. In ancient Saxon times the householder was bound to provide for the labourer, and men who had no master were, by the Folknote, assigned to some householder; but when freedom began to prevail this state of things gradually fell into disuse. It is now thrown on the ratepayers to provide for the freeman, and when he failed to provide for himself, by honest labour, he generally took to vagrant begging, often to violence. The statute of Winchester (13th Ed. I., 1285) shows the poor utterly-neglected by the law, and allowed to prey on the unfortunate. Up to the reign of Richard II. the sole idea of English rulers was to treat pauperism as a crime, and repress it by punishment, and by the
most unjust and absurd restrictions on the freedom of labour. The 23d Ed. III. forbad giving alms to vagrants, on pain of imprisonment; and then the laws of settlement had their origin in the attempt to drive the poor labourer to the land. The 12th Rich. II. (1385) was the first statute that makes provision for the impotent poor. The statutes of Henry VII. endeavoured to carry out, by the severest measures, the system of repression. The 27th Henry VIII., chap. 25 (1540), established the principle of compulsory assistance. Each parish was to receive and provide for the impotent, and set the able-bodied to work. Alms were to be collected into a general fund, and indiscriminate almsgiving was forbidden, on pain of forfeiture of ten times the value given. The sturdy beggar was to be whipped when first caught, next to have his ears cropped, and for a third offence to suffer death as a felon and enemy to the commonwealth. In 1547 the following penalties were substituted—viz. branding, on first conviction, with a V on the shoulder, and being adjudged a slave for two years, to be claimed by any one, fed on bread and water, and caused to work by beating, &c. Running away from this tender treatment was punishable with S branded on the face, and slavery for life to the town or parish, on the roads of which the incorrigible beggar was now found necessary to obtain funds for the maintenance of the poor. The collectors were gently to ask every man and woman at church what they would give; but if one could not be persuaded, the bishop was to send for the recusant, and use charitable wiles and means. At last, in the 5th Elizabeth, chap. 3 (1563), provided that he who obstinately refused to give should be handed over to the justices, who were empowered to tax him at their discretion, and send him to jail for default. Ten years later the power of compulsory assessment is given to the justices, and abiding-places are ordered to be provided for the aged and infirm. These statutes culminated in the 43d Elizabeth, chap. 2 (1601), which has formed the basis of the poor-law system of England up to the present time, and was adopted by almost all the parishes of every town and village for the relief of the poor. It directed the justices in every county to appoint three or four substantial householders in each parish to be overseers of the poor, along with the churchwardens. It ordered the relief of the impotent, and the support of old people, and the peaceable able-bodied for the able by means of a convenient stock of flax, hemp, wool, thread, iron, and other necessary ware and stuff.

The great Act of Elizabeth came but slowly into operation. Up to the reign of Charles I., there were many parishes in which no rate was assessed, and which turned away their poor; but the great evils had been remedied, and there is little legislation on the subject for the next hundred years. The 3d William and Mary, chap. 2 (1691), provides that the vestry shall examine the rates, and the parishes pay the rates according to the result of the examination by the vestry, because evils had arisen out of the unlimited power of the churchwardens and overseers giving relief 'for their own private ends,' by which the charge on the parish was greatly increased, contrary to the true intent of the statute. This set the principles of the 23d Ed. III. to the justices to order relief in cases of emergency, a provision which afterwards became a fruitful source of difficulty. The evils henceforth complained of were that many had thrown themselves on the rates, which were paid by a few of the parish; that the parish was found interfering with and displacing industrial labour; that the overseers were acting with unchecked dishonesty; and justices, with restrained liberality, ordering the money of the industrious and prudent to be spent upon the idle and improvident. Efforts were made to remedy these abuses throughout the reigns of the first three Georges, by making the justices act with the overseers, by removing them when necessary, and compelling the parishioners by means of returns and the power of inspection, and by the offer of the workhouse to all applicants for relief. This last provision, made in the reign of George 1. (1728), substituted what is called indoor relief for the allowance made to the poor at the workhouse, and the workhouse system. The workhouse established on Locke's suggestion by Carey at Bristol was one of the earliest. All who refused to be lodged in the house were to be struck off the poor's roll and refused relief. A great increase in the number of workhouses took place; guardians were appointed to guard the pauper children from neglect and improper conduct, and other attempts to improve their administration made. Workhouse Unions were also introduced by Gilbert's Act, 1782, and a succession of acts passed for the protection of parish apprentices. Towards the close of the 18th century a great relaxation took place in the treatment of the poor. The famous Spenhamland Act of 1793 meant the establishment by justices of a minimum rate of wages. The 36th Geo. III., chap. 10 and 22 (1815), ordered the extension of the point, and tended the application for relief. It repealed the workhouse test, and allowed relief to be given in aid of wages. Henceforth outdoor relief became the rule under a variety of systems, which practically turned the poor-laws into a mode of paying wages. In 1891 the amount of these rates was reckoned at £4,000,000. In 1820 it had risen to £7,300,254, the justices being now the 'rating' as well as the 'relieving' authority.

In 1817 a commission of the House of Commons stated their opinion that, unless checked, the assessment would swallow up the profits of the land. Though the two Vestry Acts, which resulted from the commission appointed in 1817, seem to have done something to remedy the evils complained of, a new commission to inquire into the operation of the poor-laws was appointed by Parliament, and this in February 1832. The evidence brought before this commission, with which the names of Bishop Blomfield, Sturges-Bowme, Edwin Chadwick, and Nazaar Senior are always connected, revealed disastrous things. There was want, deficiency, poverty, exhaustion, debtor, and domestic virtue of the lower classes were in some places nearly extinct. The great source of the evil was shown to be the relief afforded to the able-bodied in aid of wages. This aid at first reduced the expenditure in wages, and found favour with farmers and magistrates, who framed scales of relief in accordance with the wants of the people. Five modes of outdoor relief were found in operation: (1) Relief without labour; (2) allowance given, in aid of wages, according to the number of the labourer's family; (3) the Roundman system, in which the labourers were let to the parish, among the employers round; (4) parish work, generally on the roads; (5) the labour-rate, the ratepayers preferring to divide among them the parish, and to pay for it, however valueless, instead of raising a rate. Diminished industry ate away the very root of capital. Farmers turned off their men, or refused to employ them at fair wages, thereby causing a surplus of unemployed labour; they then took them back from the parish at reduced wages, paid out of the rates. From starving the parish came the reply to the queries of the commissioners: 'All our able-bodied labourers receive allowance.' No poor man in such parishes could save; if it was known that he had a fund of savings 'he would be refused work till the savings
were gone, and he had come down to the pauper level. In many places pauperism swallowed up the upper class; discipline, and employment. Poor-law administration confined to the rural districts; it extended all over the country, and into the manufacturing towns, where outdoor relief was a source of constant imposture. The administration of indoor relief was also full of abuses, from want of classification, discipline, and employment. Better food and lodging were provided for idle paupers than working people could procure—better, even, than could be afforded by many of the ratepayers.

In 1834 the commissioners reported that they found the administration 'opposed to the letter and spirit of the act, and destitute of all idea of the well-being of the community.' The commissioners laid down the principle that the condition of the pauper ought to be below the lowest condition of the independent labourer, because every penny bestowed in rendering his condition more eligible is a bounty on idleness and vice, and recommended (1) the cessation of outdoor relief; (2) a central authority to control the administration; (3) unions for the better management of workhouses, and the classification of their inmates; and (4) a complete and clear system of accounts. The bill embodying those recommendations, April 23, 1834, passed its second reading in the House of Commons with only twenty dissenting votes, and became law on the 14th August, as the 4th and 5th Will. IV. chap. 76. This act was not a change of law, but of administration. The orders of the new board restricted overseers, on the formation of a union, to the collection of rates; appointed paid relieving-officers to dispense relief under the directions of the unpaid Boards of Guardians; required the gradual withdrawal of outdoor relief; and enforced classification and discipline in the workhouses. A rapid formation of unions took place under the new board. In the first eight months 112 were formed including 2066 parishes. The pauperised districts experienced a great and immediate relief, numbers of paupers going off when they found that relief involved adequate work or the strictly-disciplined workhouse; wages rose, and the expenditure was reduced on an average 20 per cent. At the accession of George 1. in 1714 the poor-rates amounted, as nearly as can be estimated, to £500,000, equal to 3s. 4d. per head on the population of 5,750,000. At the accession of George 11. the poor-rates were £2,000,000, equal to 6s. 8d.; while in 1834 the population, estimated from the last census, was 14,372,000, and the money expended in relief £2,317,255; equal to 8s. 9d. per head.
